In keeping in touch with the situation it has been found desirable to use a map showing graphically sales conditions in the territory. Installations of trucks are posted by means of pins which are colored to represent makes of our leading competitors. Where there are too many trucks in a given territory to make it impossible to put in a pin for each vehicle, a tack is used, on the head of which is written the name of the vehicles. From this map the sales manager can see at a glance the various kinds of trucks in the different parts of the territory. He can detect any change in conditions from day to day and see that special attention is directed where it is needed.

The advantages of this system in the period of vigorous competition and sales effort upon which we are entering can hardly be over-stated. They have been so great that the extension of the system to cover the entire country is inevitable. The cost has proven very small in comparison with the increased sales, increased earnings and decreased cost, both for selling and manufacture.

Less Gasoline from Natural Gas

DR. R. P. ANDERSON, chief chemist of the United Natural Gas Co., who spoke some time ago before the Western New York Section of the American Chemical Society on natural gas and the natural gas-gasoline industry, brought to light the interesting fact that the probable decrease of natural gas-gasoline during the next year or two will be felt in the gasoline industry, because natural gas-gasoline is a volatile constituent of many commercial gasoline mixtures. By the use of the highly volatile natural gas-gasoline, it is possible to make use of the gasolines of low volatility in even cold weather. The failure of natural gas through Ohio and Pennsylvania, which are the two leading natural gas States, is naturally going to have a similar effect on the natural gas-gasoline industry.

Dr. Anderson also pointed out the increasing use of the absorption methods of manufacturing natural gas-gasoline. This, he stated, is a result of experiments during the war on the high absorption qualities of charcoal. This development is going ahead very rapidly and plants using it are running at 50 to 75 per cent efficiency, which is higher than by previous methods. It is also found possible by this method to extract the gasoline from natural gases which are very lean in gasoline and from which it is practically impossible to get results with the compression method which was previously used.

Conditions in Bulgaria Favorable to the Tractor

In this interesting article the writer makes very clear the need of long term credits if we are to sell our products in the war worn countries of Europe. Here is a country that needs tractors, but cannot buy them.

A. M. Gheorghiew*

BULGARIA is essentially an agricultural country. Eighty-two per cent of her population are peasants and the economic life of this country depends in the first place on its crop. In spite of this the methods of cultivating land are relatively primitive and the use of modern machines is limited. The causes of this unfavorable situation are of different kinds. The short period since the liberation of the country from the Turks (1878), whose régime always paralyzed any development of productive forces; the division of the land into small parcels, resulting in the insufficient purchasing power of the farmers and the difficulties in using machines in a profitable way on such limited areas; the lack of technicians and adequate workshops.

Change in the Situation

Nowadays conditions are changing in many respects. Owing to the almost uninterrupted wars since 1912 to 1918, the country is economically exhausted; we need to increase production to the utmost and, conforming to our conditions, firstly by speeding up our agricultural activity, in order to cover our liabilities and to rehabilitate our finances. On the other hand, during the war a big percentage of our cattle was lost and must be replaced in some way. Our farmers already understand, that our ground, being fertile, requires intensive working. Lastly, the lack of transport facilities outside the railroads handicaps the development of export, especially of cereals. All these requirements could be satisfied by introducing on a larger scale up-to-date and proper agricultural machines, tractors and also trucks.

In the present article we shall consider only one of the most important machines of modern agriculture viz, the motor-plough. Bulgaria is now just entering the phase of "industrializing" her agriculture, a situation which has been experienced by more advanced countries many years ago. As we have already mentioned, there are serious hindrances in the way of modernization of agricultural methods, but the necessity of efficient machines is so evident that all obstacles will be overcome. It is also of importance that our present government created by the "Agrarian party" is paying particular attention to the strengthening of our farming activity.

Trials and Their Results

The first serious trials with motor plows were made in our country during the last war, especially on the Dobroudja, called the "gold" country and "granary" of Bulgaria. The results were excellent. Unfortunately, Dobroudja with its vast and fertile plains, highly suitable for motor plowing, no longer belongs to this country, as a result of the peace treaty. However, we have still important districts where motor plows could be utilized successfully. The principal point is to proceed systematically, to supply the farmers with the best types of machines for this country and to show them how to extract the largest profit from them. With this object in view, our government arranged in August last, in the neighborhood of Sofia, the first systematic trial of motor plows.

The following firms were represented there: Case, 10/18 hp., plow with three shares and 15/27 hp., plow with four shares; Fiat, Romeo, 24 hp.; Moline; Frick, 25 hp., plow with three shares and Traga, 40 hp., plow with five shares.

In these trials the Case tractor gave the best results, the second place being taken by a Fiat. The opinion of both the expert commission and the Director of the Agricultural Bank, who was president of the commission and with whom I had the chance to have an interview, could be summarized in the following statement.

1. In view of the particular working conditions in this country, tractors of medium power with plows of 2-3 shares are the most suitable.
2. The tractor system with detachable plow is preferable to the rigid one.
3. Apart from plowing, the tractor must be suitable for the transport of goods, driving of threshing machines, pumps, etc.
4. The consumption of fuel must be reduced to the lowest possible (very important), taking into consideration the extremely high prices of petrol, etc. (chiefly due to the depreciation of our money; the price of a litre of benzine rose from 0.35 Leva in pre-war time to the fantastic figure of 14 Leva). A more expensive machine with reduced consumption will be in general preferred to a cheaper one, which wastes fuel.
5. The carbureter must be adapted for benzine, benzol and kerosene.
6. The whole machine must be suitable for plowing in a rough country.
7. Two types of shares to each motor plow—one for heavy and the other for medium and light ground —are desirable.
8. In view of the lack of technicians, the construction, and especially the operating of the machine, must be simplified to the utmost.

In order to obtain the most efficient use of the motor plow, and for its rapid introduction, it will be also advisable to carry out the following suggestions:

a. Facilitate repairs in well-organized workshops, distributed in the most important centers of agriculture.

b. Provide a technical control by means of traveling mechanics.

*Mr. Gheorghiew is connected with government promotion of automotive equipment in Bulgaria.

c. Secure fuel and lubricating oils of good quality, at reasonable prices.

d. Propaganda accompanied by demonstrations. The best way for meeting the above mentioned suggestions will be, apart from the co-operation of the government institutions, the establishment of agencies of important manufacturers in Bulgaria.

After the trial in the past year the general opinion was that the introduction of motor plows in this country would give the best results. But the rate of exchange being greatly against us (the nominal value of the dollar is 5.25 Leva and during last year it rose on the average to 80 Leva), the prices of the machines and the fuel were too high and, therefore, motor plowing seemed to be, however, not profitable. Thus, the purchase of motor plows was postponed. But as the exchange remains still in the same state and the need of the machines in question for our farms is acute, the government decided to repeat the trial in May this year and then to start modernizing farming in our country.

The conditions in the judging of the motor plows will be almost the same as at the preceding trial. The strength and the suitability of the construction, the efficiency of the machine, working cost, quality and quantity of the work, repair facilities secured by the firms, will be of first importance.

The depth of the furrows will vary from 8 to 24 cm. when working on a gradient of 7 per cent, the required depth will be 17 cm. It deserves to be mentioned that the results of the trial, as was the case last year, depend, in a great degree, on the skill of the mechanics. It seems that the next trial will be organized on a larger scale and that more firms will compete.

Suggestions and Conclusion

As we have already stated, all the difficulties of a technical and financial nature in popularizing and extending the use of motor plows will be overcome by the necessity of increasing production by improved farming methods. This opinion will be endorsed, especially when one bears in mind that the general state of education in Bulgaria is very good. There are almost no illiterate people in Bulgaria so that the utility of the machines is rapidly understood by all the classes of the population. But manufacturers and dealers interested in this line could considerably facilitate and expedite the industrializing of Bulgarian agriculture both to the profit of the country and to their own advantage.

Besides the technical facilities needed for that purpose, it would be of great importance to hasten this process also from the financial standpoint. It is true that as a consequence of the war, the purchasing power of the farmer increased considerably in comparison with that of the citizens.

But, on the other hand, the depreciation of our money hampers the sale of foreign articles in the Bulgarian market.

The credits granted to our farmers by manufacturers of agricultural machines had, as a result, the remarkable increase of orders for such machines during the last years before the outbreak of the war. Such credits are now still more required (because of the unfavorable rate of exchange) in order to enable the farmers to acquire machines. On the other hand, the Bulgarian peasant and citizen were known in the Balkans as good payers, so that no risk would be faced, when allowing such credits, if conducted in the proper way.

Finally, we should emphasize that the Bulgarian market could play a much more important rôle in the near future than could be expected of it in proportion to its limited area. The nearness of Bulgaria to Southern Russia—this enormous field for agriculture, which, in normal times, feeds the great empire and in addition to that exports large quantities of cereals—could favor, firstly, the organization of the supply of machines to Russia (when she will open) and, secondly, **would allow her to make use of Bulgaria as a big trial field for farming machines destined for Russian markets.** Before the war (and undoubtedly some time later again) many Bulgarian peasants used to go to the Southern Russian districts for temporary work and they were there received always in the best manner as good agriculturists. Those people are also capable of facilitating the introduction of such machines in Russia as proved to be adequate in the Balkans. And it is doubtless that, when Russia recovers, its market will be of extreme importance for the exporters and in the first place for those interested in the agricultural machinery and implements.

We hope that the facts pointed out in this article will serve to awaken the interest of the makers engaged in the manufacture of agricultural machines to the attractive prospects of this country.

Trucks Used in Warehouse Industry

THE warehouse and transfer industries offer a lucrative field for the sale of motor trucks. *Distribution & Warehousing*, the business paper of the warehousing interests, recently compiled information for incorporation into its 1921 Warehouse Directory and in the questionnaire which was circulated there was included an inquiry as the use of motor trucks and horses in the distribution of manufacturers' products and in the transport of household goods. The responses indicated that the horse is being retired from warehousing and that the motor truck is generally favored.

The direct inquiry about teaming facilities was answered by 1064 warehouse and transfer companies. Every one of the transfer interests operates one or more warehouses.

This tabulation shows an average of nearly six trucks to a company. The inquiry as to teaming service was left unanswered by many of warehouse companies which are employing the commercial vehicle, but the tabulation is definite in its indication of the field that is there for the truck manufacturer.

The replies from these 1064 companies supplied the following statistics:

Tons Capacity	Number in use
1	952
1½	416
2	1343
2½	484
3	387
3½-5	716
Above 5	479
Unclassified	1272
Total	6249

Some warehouses are operating fleets which run as high as fifty or sixty trucks. These are used for distributing shippers' spot stocks held in the storage plants or goods which have arrived in carload lots. Some of this distribution is carried on in zones which extend several hundred miles from the warehouse.

In the 6249 trucks there were 176 different makes represented.

Why Southern Ports Cannot Compete for Export Shipments

Financial arrangements, say the practical men, are of more importance than the saving of freight costs by using the shorter and more direct route. Experience shows that rail shipments are preferred to water when rails reach the destination.

By H. H. Dunn*

THE fact that virtually all automobiles manufactured in the United States and sold in foreign countries are so sold to be paid for with drafts on New York, sent with the bills of lading, has practically eliminated the gulf ports as points of export for either passenger cars, trucks or tractors. During the period of freight congestion in New York, a few months ago, a number of Wichita trucks were shipped through New Orleans to India, being handled down the Mississippi on barges, and transshipped here, while about 100 Dodge, Ford and Hudson passenger cars were sent through New Orleans to Latin-America, but as soon as the congestion was relieved at New York these shipments stopped and no further shipments were made.

While shipment of automobiles and trucks from the factories in the upper Mississippi Valley, by the all-water route to New Orleans, and thence on steamer, especially to Latin-America and the Orient, is somewhat cheaper as regards freight costs than the shipment by rail to New York, with the added distance from that port to the Panama Canal, lack of suitable financial arrangements at Gulf Coast ports more than offsets this freight saving.

The majority of the automobile manufacturers of the United States maintain export departments or agencies in New York, and have no such departments on the Gulf Coast. The actual technical business of exporting, arrangements for packing and crating, and for short-time payment for exported cars and trucks, are thus far more easily carried on from New York, and until such departments are established in New Orleans, Mobile, Galveston, Houston, or other Gulf Coast ports, there is little prospect of automobile export traffic worth mentioning from any of these ports.

Recently the company which manufactures the Ranger car in Texas shipped a number of its cars to Mexico City dealers. Despite the fact that this company is located in Houston, and that Houston is virtually a deep-sea port, the cars in this consignment were shipped by train to the border and thence over the National Railways of Mexico to Mexico City and other points of distribution in the southern republic. This would indicate that, in addition to lack of financial and other shipping conveniences at gulf coast ports, automobile shipments by train are more satisfactory than by steamship.

These are the opinions of the shipping men and steamship agents of New Orleans, as voiced by A. N. Floyd, general manager of the New Orleans and South American Steamship Co., one of the principal lines operating into the ports of Latin-America, and connecting with Pacific Mail and other steamers on the western side of the Isthmus of Panama.

"We have tried, and other steamship companies and agencies in Gulf Coast ports have tried, to lay the foundations for an automobile export business from these southern ports," said Floyd, "but so far we have been unable to do so. We sent trained men into the automobile manufacturing centers through the upper Mississippi and Ohio valleys and around the Great Lakes, but we found that financial and shipping arrangements were so much better through New York that we could not compete with the north Atlantic port, at least until we had similar arrangements as to export departments and financing in the southern ports.

"All automobiles sent by sea have to be crated, costing approximately $100 for each car. The trucks and other cars shipped through New Orleans during the period of freight congestion in New York some months ago were sent unpacked to New Orleans, crated here, and then placed on board the ships.

"While the rate by barge line down the Mississippi River, from St. Louis to New Orleans, is some 20 per cent cheaper than the rail rate, the manufacturers seem to find that rail shipments to New York are more satisfactory than by water southward to these ports. Whatever the cause for this, there is little prospect of increased automobile export business from any of the Gulf of Mexico ports of the United States until payment can be made by drafts on bills of lading through the banks of these ports, and until export departments of the various automobile manufactories are established here."

The automobile dealers, and distributors, some of whom have tried, in a limited way, to export a few cars to Latin-America, hold the same opinions as the shipping men, but go somewhat further in their discussion of reasons for the lack of such exports.

"There is no use in attempting to export cars or trucks from the gulf ports," said one distributor, "until the gulf ports wake up to this great industry and are willing to operate 'fifty-fifty' with the would-be exporter of automobiles, the way the banks in New York do. If we handle cars out of here to any Latin-American country, instead of getting paid with New Orleans, or Mobile, or Galveston drafts, we have to take New York drafts on our bills of lading. This slows up the deal and inconveniences the New Orleans exporter.

"Then, too, the business of exporting automobiles, trucks or tractors to Latin-America is precarious because of the lack of facilities for making collections through New Orleans banks. Most of the dealers and distributors of automobiles in Latin-America, unless they are American

*Class Journal correspondent at New Orleans.

or British firms, want all the time they can get, and they figure on 30, 60, 90, or 180 days from date as exclusive of the time required for the automobile shipment to travel from the point of shipment to them, and as exclusive of the time required by their remittance to come from their city to New Orleans. In cases where such time amounts to 15 to 30 days each way, as it does between the gulf ports and some of the cities on the west coast of South Africa, or in the interior of Mexico or Central America, this is a serious matter. More frequently than not, the local exporter has to put up his own money for from 30 to 60 days, no matter how good the Latin-American firm may be or how promptly it may remit.

"If we had branches of the export departments of some of the automobile and truck manufacturers here in New Orleans, or even in Galveston, Houston, Mobile, or some other of the gulf ports, or if we had foreign bank connections here which would handle the paper of these Latin-American buyers, we might do some business, but as matters stand, I'm off the auto export end of it for life."

Still another dealer, who operates in New Orleans on larger capital than most dealers, and who has been able to swing some export deals through the use of his own money, talked along another line about the matter of exports from the gulf ports. Said he:

"I doubt if the shipment of passenger cars by boat to Latin-America ever will be as successful as their shipment by rail. Every day a car stays on the water damages it; there is no question about it, and I have had to knock many a hundred dollars off the price of cars I have sold in Latin-America because of rust and other damage from the salt water and salt air. This is especially true when shipments are made far south on the east coast of South America, or when they are made to almost any point on the west coast of that continent, involving trans-shipment at Panama.

"Experience has taught me that is is impossible to so crate or pack an automobile, whether entire or 'in the flat,' to protect it from the effects of this dampness, and, to be perfectly frank with you, I should like to have seen those trucks which were shipped through New Orleans to India a few months ago, though, naturally, the heavier and coarser metal of the truck or the tractor suffers less from this corroding salt air than does the finer passenger car."

A Removable Track for Rubber Tired Road Vehicles

THE present development of army combat transportation requires cross-country vehicles which are also able to travel on good roads at the speed of conventional motor trucks. Previous forms of caterpillar tracks were usually developed for low-speed agricultural purposes, and high speeds were difficult to maintain, due to the wear and the mechanical losses in the track itself. Increased efficiency is attributed to the fabric track illustrated. Running on its wheels, the car can make about 45 miles per hour. With the tracks applied, a maximum speed of 37 miles per hour on good roads has been attained, which, so far as is known, is the highest speed ever developed by a track-laying type of vehicle.

Each track consists of two rubberized fabric belts which are connected together by steel stampings riveted to the belts, the ends of the stampings being turned over to the inside so as to form a guide into which the tires fit. Any clogging material which may lodge on the upper side of the track is forced through the large opening in the track, which is a feature of this type of construction.

Ford Runabout Equipped with the Chase Track

In addition to the regular wheels of the car, there are provided four extra wheels, two on each side, of the same size as the regular wheels and located between the front and rear regular wheels. These extra wheels serve as carriers, the track under the regular wheels being normally off the ground. Standard regular 3½-in. pneumatic tires are used, and after 1300 miles of operation, under conditions which would have damaged the tires of a regular Ford, the tires and fabric track showed no wear. There was a nominal amount of wear on the replaceable steel cross links.

For steering, a pair of separate brakes is provided which permit of locking the driving wheel on either side. The regular gear ratios of the Ford are too high for this vehicle to operate satisfactorily in soft ground, deep mud, wet marsh, etc., and a commercial auxiliary transmission, which doubles the gear reduction, is introduced in the drive shaft directly in front of the rear axle housing. For operation on improved roads, the regular Ford ratios are used. For cross-country running, the lower set of ratios is used.

In the accompanying photograph a Ford car is seen equipped with the removable tracks to adapt it for use on deep snow, "bottomless" roads, plowed ground, etc. The track was developed for the Tank, Tractor and Trailer Division of the Ordnance Department by A. M. Chase, who is in charge of its Syracuse engineering office.

The FORUM

Tire Pressures as Affecting Car Life

Editor AUTOMOTIVE INDUSTRIES:

The following paragraphs in the February number of *The Automobile Engineer* attracted my attention:

"Although under-inflation of tires is in direct opposition to the most explicit instructions issued by the tire manufacturers, there is little doubt that harmful results are confined almost entirely to the tires of heavier cars, and the tires of lighter vehicles do not evidence the rapid depreciation threatened by tire makers. In any case, it is better that the tires should be damaged rather than that the chassis and components should suffer.

"Apart from the usefulness of the flat tire on demonstration cars, those who have driven cars with relatively under-inflated tires would on no account return to the old practice of running their tires at catalogue pressures. The point of road contact being the place where the shock commences, it is evidently the correct place to absorb any but the largest movements, and the contact spot on the tire, with its minimum inertia, is particularly suitable for this purpose. If tires as now produced are not manufactured to resist this continued flexing, then there is need of further development."

This is a subject I have talked about a great deal and which I believe is worthy of consideration.

Of course, I do not believe in carrying tire pressures ridiculously low, but at the same time I feel that the tire pressures at present recommended by the tire manufacturers are entirely too high. They may save on tires somewhat, but I believe that they do more damage to the car, and decrease the riding comfort so much that the extra tire mileage to be gained is not worth while.

On experimental cars, when we want to abuse them, we pump the tires up real hard, and when we want to ride with comfort, and travel for pleasure, we deflate them to 50 lb. pressure for a 32 x 4 cord tire.

I have seen owner's cars come into our service department that have been pumped up so hard as to give the impression of riding on solid tires. Give a man a set of tires inflated to the tire manufacturer's recommendation, and then put him on the average macadamized or paved road, in its usual run down condition, and he is pretty sure to find himself in the repair shop in a very short time.

RUSSELL BEGG,
Jordan Motor Co.

Suggestion to Bus Builders

Editor AUTOMOTIVE INDUSTRIES:

Having occasion to ride in various motor omnibuses of either the front-entrance type or such as have no open rear platform, I have almost invariably been conscious of a strong odor of exhaust gas, particularly in the after part of the body. Due to the peculiarities of the air currents about the moving vehicle, such gas enters the body chiefly at the back and somewhat through the floor, the sides being swept by fresh air.

Since this gas is lethal, I believe it should be obligatory on those who outfit buses to render them gasproof, even to the extent of sealing the floors and backs airtight; further, the chassis builders should pipe the exhaust to a point whence it will not be swirled along in the wake of the machine.

The next step, of course, is for the engine and carbureter makers so to adapt their products to the fuel as to secure more complete combustion with less noxious residue; but this will take time and cannot be counted on as an immediate palliative of the poisonous conditions in buses.

It would be a unique achievement if bus makers and owners both could take gas-exclusion measures on their own initiative before statutes and local ordinances compel them to; certainly, these considerations should not be overlooked.

KEITH ROLLIN MANVILLE.

Hempstead, N. Y.

Swash-Plate (Inclined Disk) and Z-crank Engines

Editor AUTOMOTIVE INDUSTRIES:

IT seems that at present a great deal of labor and money are being spent on the construction of engines, in which no ordinary crankshaft is used, but an inclined disk, fixed to a shaft, or a Z-crank with wobbling member.

This type of engine seems especially fitted for very high speeds, and may be designed to give very attractive engines. However, there is a hidden difficulty, and one so serious that these engines don't seem to have any future. As this difficulty may well escape even the attention of a thorough designer, and in most cases will only appear during tests of the completed engine, and as writer has himself for years been connected with the manufacture of such an engine, he thinks it useful to all who are planning in this direction to call attention to this difficulty.

To prevent the member, to which the connecting rods are attached, from turning, it is connected to the engine frame by some kind of universal joint. This results in the necessity for this member to perform very quick oscillations; as the frame does not revolve, and the axis of the wobbling member constantly changes its direction, it may be easily seen that because of the well-known periodical speed fluctuations of a universal joint, the wobbling member itself will slightly oscillate around its own axis. For each revolution of the engine the wobbling member oscillates two times to and fro. Though the oscillations are very small, in most cases only a few tenths of an inch, the forces which come into play are excessively high on account of the enormous speeds, and rather big inertia.

The problem of the construction of these engines is hidden in the construction of a universal joint which will transmit motion absolutely uniformly. H. C. O.

THE Geological Survey Branch of the Canadian Department of Mines reports that the oil fields of northern Canada comprise 300,000 square miles.

Uses and Abuses of Organization and Associations

We have organized ourselves into a confusion of effort that is likely to retard the adjustment of our own knowledge. Mr. Tipper commends an organization recently established for purposes of research, but points out the excess of organizations devoted to the development of systems.

By Harry Tipper

IN the March 31 issue of AUTOMOTIVE INDUSTRIES I wrote an article entitled "Standardization Without Understanding Is Harmful," and in the fore part of that article I quoted from the New York "Times" concerning a meeting sponsored by Mr. G. K. Parsons, which was apparently called for the purpose of standardizing methods of selecting individuals.

Since that time Mr. Parsons has brought the matter to my attention and explained the plan of the committee. The plan as it has been started is different from the report in the "Times," and it is evident that the account which was printed failed to secure the right attitude as to the proposals.

The committee was called for the purpose of considering all the different methods for selecting men adopted by various concerns and organizations, and attempting to evaluate these methods by research and experiment. The idea of the committee is to find out what elements of value there are in each of the methods adopted and suggest the use of the things which have been found of fundamental importance and the elimination of those things which cannot be considered in that light.

This purpose is a worthy one, and one which can be of benefit in connection with a study of humanity in industry. Glaring errors in our present methods may be determined by a series of researches along these lines, and whatever is done in this direction will be on the lines of progress.

The difficulties which face such a committee are very great. In order to evaluate there must be a basis of appraisal, and our knowledge of human qualities, variations and necessities is very meagre. The most difficult part of a work of this kind will be the discovery of any basis upon which the valuation can be determined, and it will be unfortunate if the weight of organized opinion approves a method without a careful determination of the basis upon which that method is valued. However, the object of the committee is worthy, and it is interesting to discover an organization which is gathered together for the purpose of research rather than standardization.

This reference to organization reminds me that papers concerning three new organizations, having to do with the human side of industry, have passed across my desk this week. The number was sufficiently interesting to induce me to trace previous records of such organizations. At least thirty have been formed in the last year, and at the present rate of progress they will reach over a hundred in a very short time.

This craze for organization is leading to such a multiplicity in the organized work connected with co-operation, management, employment, personnel, industrial relations, human engineering, so called, and other elements of the human side of industry that the present confusion of mind is likely to be greatly enlarged by these endeavors.

We have considered organized effort as so vital a part of research experiment and propaganda that every idea, every method and every suggestion must be made the object of a committee, a conference or an association with its formal organization and its formal methods of examination and development. In the belief that organization as such is necessary to progress, we have organized ourselves into a confusion of effort that is likely to retard the adjustment of our own knowledge. In reality this is another visible symptom of the way in which we have depended upon system and systematized work to take the place of understanding and thorough definition.

The functions of these organizations interested in the human developments of industry are very much alike, none of them covering the field basically, and most of them devoted to the development of systems and methods rather than of examination and research. Committees, associations and conferences are excellent organizations for the purpose of arriving at agreements upon known facts, standardizing known practices and developing orderly methods. They have not proved themselves of value in research and they are not likely to be of much service in this respect.

It is not in the number of authorities who may discuss a subject that new principles are discovered, but in the patient research of some man who is willing to devote his life to the development.

Discoveries and improvements in the mechanical arts have not been due to the efforts of committees or associations; they have been the result of individual research in each case. When the discoveries have been made and the basic elements of practice established, the organized bodies have been of great value in standardizing and developing the operations by which these discoveries could become valuable to the general public. There is no reason to suppose that the methods of advancement will be any different in our progress in the human side of industry. In fact, our ignorance of the matter, the meagre amount of knowledge we possess and the large amount of conjecture in our method make it unlikely

that organized bodies can be of any great value in the development of our knowledge upon these subjects.

Very few men in industry, even among those who are especially interested in the human side, have studied deeply the fundaments of human necessity, progress and reaction. The work of these men is not likely to be forwarded by the actions of organized groups composed largely of men who are versed in methods of examination, but have not studied the fundaments upon which those methods should be based.

We have so much machinery of co-operative organization that it has become unwieldy and cumbersome. The objects of our organized effort are but poorly defined, and in many organizations few of the members have a clear idea as to where they are going or what they are attempting to do.

Co-operative organization presupposes a co-operative object and method. In discussions with the officers and secretaries of many organizations it is impossible to discover any well-defined reason for their existence or any well-defined method for their development.

One good organization with a clearly defined object in front of it and with a definite method of development would be worth a dozen of the present organizations and of more value to business.

In the meantime it is well to remember that conclusions of an organization as to the validity of present methods and their use are the result of the average intellect in such an organization, and cannot be in accordance with the best practice of the most advanced students.

The man of sound knowledge and wide experience is ahead of any organization in the development of his practice. The value and purpose of the organization is limited to a comparison of individual methods and the general dissemination of those methods, so that all interested men may be able to avail themselves of the studies. So long as they are limited to discussion for the purpose of clearing the individual experience and practice, they have great value in enabling each practitioner to enlarge the horizon of his practice. So long as they are content to organize the known factors and to recommend methods valued upon known bases, they have their place in the industrial necessity.

Unfortunately, on the human side of industry, methods have been standardized without a proper knowledge of the fundamental bases, practice has been organized without the proper examination of its objects and purposes, and the present actions have tended to solidify the errors in the endeavor to standardize the values.

It might be an excellent thing for us in our co-operative associations in industry to consider the advisability of organizing our associations, eliminating those which are unnecessary and defining those which are of value so that the objects and purposes are clearly understood.

Good Roads Essay Contest

VARIOUS Government agencies and national organizations are announcing to-day the new Good Roads and Highway Transport national essay contest, to be open to all pupils of high school grade. The national prize is a four-year scholarship in the university or college chosen by the successful contestant. It is offered by H. S. Firestone.

The contest will be conducted by the Highway and Highway Transport Education Committee, Dr. P. P. Claxton, United States Commissioner of Education, chairman, who announced to-day rules governing the contest.

Essays must be not more than 500 words and must be written on the subject, "Good Roads and Highway Transport." All essays must be in the hands of local committees not later than June 15.

Local and state prizes are to be announced soon but, according to the committee, essays winning first honors in local and state contests will be eligible to compete for the four years' university scholarship whether local and state prizes are offered or not.

Among Government agencies and national organizations co-operating to make the contest successful are the Bureau of Public Roads, of the Department of Agriculture; the Bureau of Education of the Department of the Interior, and the National Automobile Chamber of Commerce; the Firestone Ship by Truck Bureau; the National Grange; women's clubs, chambers of commerce, and automotive associations everywhere.

The contest is a renewal of the Ship by Truck-Good Roads essay contest held among high school students last year, in which more than 200,000 essays were submitted.

Miss Katharine F. Butterfield, pretty 16-year-old high school pupil of Weiser, Idaho, was the victor in this contest and is enjoying the scholarship at a famous Eastern school. As a result of her conquest, Miss Butterfield will receive a four years' college education.

Back of the idea of the essay contest is the wish of the Highway Transport Committee and co-operating organizations to bring to the attention of the high school pupils of the country the urgent need for immediate improvement in the national highway system.

Training Office Employees

THE idea of training office employees is usually connected with the idea of a large organization employing a great number of persons. New employees in the small office, however, need training if the organization is to function efficiently. This training can easily be carried on without elaborate preparation and equipment.

Three fundamentals are suggested by W. H. Leffingwell, president of the Leffingwell-Ream Co.

1. Teach the worker the purpose of the business.
2. Teach him the purpose of the operation upon which you have started him.
3. Teach him the operation itself.

"These steps," Leffingwell says, "are necessary in all training, and every one of them can be undertaken in even the smallest office, but on the other hand, in very few offices will this training be found."

LANCIA, the Italian manufacturer, has evolved a construction, recently patented in England, by which the width of V-type engines is decreased. In a twelve-cylinder engine, for instance, the axes of the two sets of cylinders do not meet at the center of the crankshaft but a distance below the crankshaft about equal to the length of the connecting rod. The axes of the connecting rods at dead centers make an angle of 20 degrees and the cranks of each pair of cylinders make an angle of 40 degrees. In this way it is hoped to obtain a fairly good balance.

Present Action Will Influence Future

THERE has been an almost universal increase in the efficiency of labor during recent months. This is due partly, of course, to the scarcity of jobs. It is, however, in some cases due to a more careful study of production problems, with a resulting weeding out of inefficients.

Other firms have taken this time as a definite opportunity to gain the active co-operation of their remaining workers and thus form a firm foundation for the future building up of an efficient working force. There has been very great variation in the attitude taken toward such problems by the various manufacturers. Speaking of efforts in connection with employees to reduce costs, for instance, one employer said he had adopted the method of trying to have the employees feel that they are working with him rather than for him. In reply to an inquiry along similar lines another said: "We are employing efficiency engineers to suggest efficiency methods," while still another believes the important thing is to "use great care not to reduce wages and salaries as fast as commodities decline. We did not raise them as fast as prices advanced."

The results of the various methods of handling the labor problem during recent months cannot be determined until sometime in the future. Much importance unquestionably attaches to the present approach to and administration of industrial relations matters.

Conscious and Unconscious Education

AN interesting statement appears in a bulletin recently sent out by the Department of Domestic Distribution of the Chamber of Commerce of the United States. The statement refers to the results of a questionnaire answered by two thousand business men through the country. It reads as follows:

"One-fifth reported that they had done away with bonuses. . . . This form of reward was, perhaps, very largely an outgrowth of war conditions, and it may be fair to guess that it is fast disappearing with return to more settled times."

The statement indicates what is probably true, that many of the bonus and similar plans installed during recent years were given not on a sound basis of reward for service or through any fundamental belief on the part of the manufacturer that the worker was entitled to a larger share in the profits of industry, but merely as a bribe. Bribery has often been known to effectively obtain temporary ends, but it is never of any value to the permanent progress of industry or society.

When wages are adjusted on this basis and in this spirit, the workman is almost certain to accept the adjustment in the spirit in which it is given. Judging on the basis of the facts presented, he comes to believe that wages are the result of economic power rather than service rendered, consequently he attempts to obtain wages on the former basis rather than the latter.

In discussing the matter of educating the worker, it must be recognized that certain factors and information go before the worker from the employer which the latter is perhaps unconscious of having given as well as does that "education" which the employer consciously transmits through speeches and house organs.

Speed Not Always Efficiency

THERE was a note in a recent talk made by J. B. Bartholomew before the Tractor and Thresher Group of the National Implement and Vehicle Association that is worthy of consideration by those connected with merchandising efforts for automotive products. Mr. Bartholomew, a veteran in the field of farm equipment operations, was speaking of salesmen. He is quoted as follows:

"We used to call them salesmen, but now they are travelers and some I call Cook's tourists."

His explanation of this was that too many of the

men on the road to-day judge their efficiency by the number of calls they make, or the number of towns they visit. Their sole ambition appears to be to jump from one town to another.

This view is not a new one to many executives. It has probably grown out of the call for more efficiency from salesmen. There was a time when salesmen were entirely too leisurely in their travel, but in making the change it is a frequent complaint that many of them are now moving about the country so fast that they really do not have an opportunity to get acquainted with their dealer customers and to learn what the dealer's troubles may be and why he has troubles.

During the period of order taking, many abuses of the merchandising systems gained a foothold and it is going to be difficult to eradicate some of them. Over speed and too little attention to the complete understanding of the deal was one of these evils. The best seal on a business deal is a complete understanding of it before signing on the dotted line, whether the customer be a consumer or a dealer. Especially is this true in Mr. Bartholomew's field. His consumers are farmers. They buy leisurely and the deals that lead up to the final purchase must be tempered with this knowledge. Some salesmen get so busy they do not have time for an understanding of business.

The Best S. A. E. Meeting

THE success of any convention depends largely upon the support and co-operation of the members of the organization who attend, and engineering meetings are no exception to this rule. At the coming summer meeting of the Society of Automotive Engineers there will be ample opportunity for recreation, but the prime object of the meeting is to afford opportunity for interchange of engineering information, and this fact should not be lost sight of by those who are planning to attend.

Members of the Society will shortly receive advance copies of most of the papers to be presented, and should come prepared to discuss these papers fully, for the life of a meeting depends largely upon the discussion, and the value of the paper often depends upon the discussion it creates. The Society and the author have discharged the bulk of their responsibility when the paper is placed in the hands of the membership. Then the responsibility of the member for making the meeting a success begins. In order that the interchange of information be carried into effect the membership must respond with pertinent comment or criticism. If the views or data set forth in the paper are incorrect or biased, let the fact be known. If they are incomplete or inconclusive, and you can supply from your own experience or records particulars which should be added, go to the meeting prepared to contribute for the general good. If you agree with the author, say so, for this adds weight to information given and assists those with less experience to arrive at safe conclusions. Finally, if you hesitate to speak at the meeting, or if you cannot attend, contribute written discussion.

Authors of papers and members of the staff of the Society spend many hours in preparing papers and arranging to place them in the hands of members prior to the meeting. After that it's largely "up to" the membership, if they purpose to make the forthcoming meeting the best in the history of the Society.

Facts and Fences

THROUGH basing every action in connection with employee relationships on utter truthfuness, as to facts, and fair reasoning, as to principles, the manufacturer can go far toward building up confidence among his workers and obtaining the good results which accrue from such confidence.

It does not assist in the ultimate solution of the labor problem to say in "boom" periods that labor costs are a very large part of manufacturing costs and that, therefore, the price of the product must vary directly in accordance with labor costs; and then to state in depression periods that labor cost is a very small part of total costs and that consequently a reduction in wages has a very slight effect upon the cost of the product.

Facts are not altered by the side of the fence upon which the speaker happens to be. The question is sometimes even given a different shade to the consumer and to the workman at the same time. Wages are reduced, and the consumer is told that wages are a small part of production costs and do not materially affect the price. The workman is told that wages must be cut so that the price can be reduced to meet competition.

Costs in one typical automobile plant are divided roughly something like this:

Materials 54 per cent.
Labor, 14 per cent.
Sales, 7 per cent.
Other expenses, 25 per cent.

This would indicate that wage reductions would not constitute anything like a dominating factor in the reduction of costs.

In any case the essential thing is to base actions upon considerations of fundamental justice and moral obligation as opposed to expediency.

Credit Standards

A NUMBER of manufacturers have been scrutinizing credits with more than usual care during recent months. Many are lowering overhead expenses partly by reducing the volume of their credit business. When asked about the methods he is using in accomplishing this reduction, one big business man said recently:

"We are more lenient on credits based on moral standards than those based on financial standards."

Here is a practical recognition of the fundamental necessity for a moral obligation between manufacturers. So strong is the interdependence of the various units of modern industry, that the whole structure rests primarily on the ability of these units to co-operate successfully. Such co-operation can be brought about only through a widespread recognition of the moral obligation in industry.

Mellon Proposes New Motor Taxes

Suggests Imposition of Federal License

Treasury Head Would Retain Excise Fees and Add Further Burden

WASHINGTON, May 1—Retention of excise taxes and establishment of Federal license taxes on automobiles was suggested by Secretary of the Treasury Mellon in recommendations for internal revenue revision which were submitted to the House Ways and Means Committee to-day. The application of these taxes was not explained in detail in the letter of submittal, but the Secretary announced that he would appear before the committee to supply further information regarding the Treasury tax program.

It will be noted that Secretary Mellon's proposals differ widely from those of his predecessor. Secretary Houston had suggested additional tax levies on the automotive industry calculated to yield $290,000,000 over and above the present rate of return. The Houston plan intended to double excise tax, levy a horse-power tax and two cents per gallon on gasoline. No mention was made of these propositions in the Mellon letter to Chairman Fordney, but it is expected that Treasury experts will discuss the suggestions in testifying before the committee next week. Dr. Adams, chairman of the tax advisory board of the Treasury under Houston, framed the former Secretary's recommendations, but did not include them in the latest report.

General Sales Tax Opposed

Mellon advised Congress that the only way to stop these additional internal taxes on automobiles and stamp assessments to an aggregate of between $250,000,000 and $350,000,000, would be to cut Federal expenditures. The Treasury believes the miscellaneous specific sales taxes and excise taxes, including transportation, amusement, tobacco and capital-stock taxes, should be retained, but fountain drink assessments and other minor tax should be abolished. The Secretary made clear that he could not recommend at this time any general sales tax, particularly if it were designed to supersede the highly productive special sales taxes now in effect on many relatively non-essential articles.

In proposing repeal of the excess profits tax, Mellon urged that loss of revenue should be overcome by modified taxes on corporate profits of a flat additional income tax on corporations with repeal of existing $2,000 exemption applicable to corporations. He said flat tax on corporate income at the rate of 5 per cent and exemptions removed would yield $400,000,000. Furthermore, the Treasury recommended readjustment of the income tax rates to a maximum combined normal tax and surtax of 40 per cent for taxable year of 1921 and 33 per cent thereafter. Secretary Mellon declared in favor of carrying forward net losses of one year as a deduction from the income of succeeding years.

The question of tariff levies was discussed briefly by the Secretary in connection with proposals for imposing sufficient new or additional taxes of wide application, "such as a license tax on the use of automobiles." He stated that if economies in Government operation were impossible, "it might be feasible to provide perhaps as much as $100,000,000 or $150,000,000 of the necessary revenue from new duties on staple articles of import, and the balance by taking more effective steps to realize on back taxes, surplus war supplies and other salvageable assets of the Government."

Would Stop Tax Exemptions

The Secretary deems it advisable for Congress to take action by statute or by constitutional amendment to prevent further issues of tax-exempt securities.

With the National Automobile Chamber of Commerce demanding that the floating debt be retired without delay, it is significant to note that the Secretary of the Treasury advised Congress that "if the country can not look to any plan for funding the floating debt to reduce the burden of internal taxes during the next two years. Substantial cuts in current expenditures offer the

(*Continued on page* 985)

TREASURY HEAD ASKS TAX ON HORSEPOWER

WASHINGTON, May 2—Secretary Mellon's proposal to place a Federal license on automobiles is a much discussed topic. Mellon said he understood about 9,000,000 automobiles would be subject to the tax, the number depending upon whether motor trucks were taxed. He believed that they should be subject to the Federal tax which he proposed.

The plan now being considered involved a tax of about 50 cents per horse power on the lower priced and lower powered cars, and a tax which might reach a maximum of $50 on high powered, expensive cars. Such an arrangement would call for a sliding scale of rates.

Aluminum Exemption Now Up to Congress

Final Appeal for Tariff Reduction Is Made by N. A. C. C. Representative

WASHINGTON, April 30—Automobile manufacturers made their final appeal to the tariff framers to-day for a reduction of the present rate of 2 cents on aluminum and crude aluminum. It was pointed out that manufacturers would find it difficult to fall in line with general price reductions, if higher tariffs were enacted, because of the increased cost of aluminum. Statistics were submitted by George F. Bauer, of the foreign trade committee of the National Automobile Chamber of Commerce, showing that the cost of aluminum in this country has increased in about the same proportion as the duty has advanced.

He declared that in 1914 when the tariff was fixed at 2 cents, aluminum sold at an average price of 19 cents per pound, and with a duty of 7 cents, under the tariff act of 1913 the average cost of aluminum was 23 cents per pound, representing a difference in the increased price of 4 cents, or nearly the amount of difference between the duty prevailing in 1914 and 1913 respectively.

Bauer stressed the fact that increases were reflected in the prices of automobiles. He submitted several illustrations showing the increased use of aluminum in the medium priced and high priced cars because of the lightness of the metal. The committee was informed that automobile manufacturers would be forced to turn to substitutes for aluminum and thereby put them at a disadvantage with foreign competitors.

Bauer accompanied Milton Tibbitts of the Packard company, and A. B. Whitbeck of the Chandler company in presenting their views to numerous Congressmen who have asked for information on the subject.

DESIGN AIRSHIP SLIDE-RULE

WASHINGTON, April 30—The design of a slide-rule for use in airship navigation has been completed by the Bureau of Standards and a report made to the three military and naval bureaus interested in this problem. Each report was accompanied by a model slide-rule. The report contained, in addition to the general description of the rule and its use, detailed instructions for laying off of all the scales and some thirty illustrated problems showing how to use the instrument. It is understood that a considerable number of these rules are being ordered by the air service.

Receiver Is Named for Austin Company

Insufficient Capital for Operation of Big War Plant Held Responsible

(*By cable to* AUTOMOTIVE INDUSTRIES)

LONDON, May 2—The appointment of a receiver for the Austin Motor Co. was not unexpected because it has been in financial difficulties for some time. The company has been handicapped since the war with too large a factory for the capital available, and it was unable to reach the heavy production needed to carry the burden. Its prospects were good and steadily improving as the output of tractors and cars increased. The Colonial trade also promised well.

Before the war the stock issued consisted of 400,000 ordinary shares and 250,000 7 per cent preference shares of $5 par value. This was increased by an issue of 1,000,000 6 per cent preference shares in 1919 and 1,500,000 10 per cent preferred shares in 1920. Ordinary stockholders last year received an allotment of 200,000 shares as a dividend. It had been said recently that the financial status of the company was assured by the backing of a private financier. Prospects improved on that statement, although creditors were none too hopeful of the situation. Quotations for ordinary stock have dropped to less than $1 and on preference stock to 50 cents.

An official legal statement reporting the negotiations for financing the company admits the difficulty in view of the continued stringency of the money market, but states that negotiations are proceeding, although it was considered necessary to conserve the interests of the business by appointing a receiver and manager.

Has Many Orders on Hand

Orders on hand are sufficient to keep the works going for some time. A special meeting of stockholders will be called to reconsider readjustment and finances.

The chief problem is to avert action by creditors, any one of whom may sue for compulsory liquidation which leaves the onus of resistance on other creditors.

The rapid fall in British car prices increases the difficulty of raising money for Austin. The outlook depends rather on personal confidence in Herbert Austin than on the economics of the situation for the coal strike is having an adverse effect on the demand for automobiles.

Austin recently announced that it had organized for the production of a light 10-hp. car on the lines of its 20-hp. model, which the new model would supplement. The new line was promised at a popular price.

Humbers have also introduced an improved and enlarged edition of their 10-hp. chassis, which has attained great popularity since it was originally put forward in 1913. The new model has an engine of 3 mm. larger bore (68 x 120 mm., 23 b.hp. at 2000 r.p.m.), and with both two and four-seated bodies is a production falling but little short of the highest grade in chassis, bodywork and equipment. It is, in fact, put forward very largely to meet a pronounced current demand for high-grade small cars.

First Mexican Show Stirs Wide Interest

(*Special to* AUTOMOTIVE INDUSTRIES)

MEXICO CITY, May 2—The first automobile show ever held in Mexico City opened at noon Saturday with a large attendance and every indication of being remarkably successful. There is keen enthusiasm among the exhibitors and dealers are optimistic over sales prospects. Even those dealers who contended it would be impossible to stage a successful show admit they are greatly surprised at the interest displayed.

Factory representatives from the United States also are delighted with the success of the exhibition, and declare the show would be a credit to New York or Chicago. There are numerous attractive displays together with a considerable number of special chassis cars.

Sales closed the first day totaled 32 passenger cars and six trucks.

The feature of the opening day of the show was a brilliant dinner in honor of President Obregon which was attended by all high Government officials, diplomatic representatives of the United States, England and France, presidents of all the chambers of commerce in Mexico City and prominent business men and financiers.

Exhibits 65 in Number

Sixty-five vehicles are displayed at the show, which is held in the New National Theater. This includes 48 passenger cars, 11 trucks and six tractors. The exhibition includes three Haynes, three Moons, three Overlands and two each of the following cars: Auburn, Cadillac, Chandler, Cleveland, Dort, Franklin, Kissel, Lexington, Lone Star, Mercer, National, Pierce-Arrow, Ranger, and Studebaker.

Single car displays are made by Apperson, Chalmers, Bour Davis, Essex, Hudson, Maxwell, McFarlan, Gardner, Mercedes, Premier and Willys-Knight.

There are two Federal trucks, two Rangers, two Service, one G. M. C., one Gary, one L. M. C., one United States and one Wichita.

The tractors shown are Ranger, Titan, Oilpull, Case, Hart-Parr and LaCrosse.

Fiat Workers Agree to Company's Terms

Factory Down Since April 1 to Resume Production—Berliet to Liquidate

(*By cable to* AUTOMOTIVE INDUSTRIES)

PARIS, May 2—Eight thousand of the 12,000 employees in the Fiat factory have signed an agreement to return to work under the owners' conditions, and it is probable that the factory, which has been closed since April 1, will resume operations in the near future. The lockout was declared by the management over the question of who should have authority to dismiss workers. The men asserted this authority should be vested in shop committees. The workers also protested against production of war material to be used against Soviet Russia. The Fiat company contended that this war material was for South America.

The Berliet company has made application to the courts for voluntary liquidation. Attempts to escape from its financial difficulties by abandonment of Marius Berliet's founder shares failed. The government opposed this plan because Berliet has not yet paid its war profits taxes.

The retail price of gasoline in France is expected to drop 20 cents a gallon this week when the Government will abolish the import monopoly and liquidate large war stocks at the present market prices, getting compensation for this loss by a tax on importation. A further drop is expected when the new law goes into effect.

The Packard Motor Car Co. is abandoning its French sales service organization.

To Reorganize Parts Service

NEW YORK, May 3—Officials of the Packard Motors Export Corp. here stated to-day that they had learned only yesterday of the discontinuance of the Packard service station at Paris. This station, which was quite extensive, has been under the supervision of the factory at Detroit and did not come within the jurisdiction of the export company. It was closed, according to information here, pending a possible reorganization by which it would come under the export division, whose general offices are centered here. The French market, it was said, would not be left unprotected long but it was too early yet to announce a definite policy.

Goodrich Sets Pace in Tire Price Cuts

Reduction of 20 Per Cent Restores 1913 Price Level—All Lines Included

AKRON, April 30—With the B. F. Goodrich Co. announcing a 20 per cent flat decrease in prices of cord and fabric pneumatic automobile tires, effective Monday, May 2, substantially all of Akron's tire companies are expected to make similar announcements within the next few days.

Admittedly the Goodrich action was entirely unexpected by other rubber companies at this time, and came as a surprise to most motorists and tire dealers. Inquiry at the Miller, Goodyear and Firestone factories reveals the fact that the Goodrich cut had not been anticipated and that these companies had not so far considered any similar action. With the Goodrich announcement, however, production and sales departments of all these companies were called into conference to discuss the advisability of following suit.

At each one of the three concerns it was stated that no prediction would be ventured as to what action may be taken, although from a standpoint of competition, if none other, it is regarded as apparent in Akron that all other tire companies will be compelled to drop prices to a level of the new Goodrich price sales.

The Goodrich price slash is admitted by officials to be a frank bid for additional business. Whether or not the cut is justified by decreased manufacturing costs is a matter of considerable debate. The cut is not regarded as justified, in view of the raw materials situation, although the price of raw materials has dropped substantially 100 per cent from peak. Small tire concerns may benefit by this, but such concerns as Goodrich, Goodyear and Firestone are known to have on hand large supplies of raw materials, purchased at peak prices last year, while Goodyear, and possibly the others, are obligated to pay the peak prices for supplies contracted for at that time, and yet to be delivered.

Price Back to Pre-War Basis

The Goodrich price reduction carries tire prices back to their pre-war level, and virtually restores prices existing in 1913. Tire prices dropped in 1913, but in 1914, due to the war, were slightly increased. From that time until last year they increased on an average of 37 per cent. Prices were cut within the last six months by practically all companies, the cut averaging about 15 per cent. Thus with the latest 20 per cent reduction, the prices of Goodirch tires, at least, go back to the 1913 level.

This is considered significant for the motorist, as the 1914 tire gave an average service of 4000 miles, while the tire of to-day has greater durability and gives a fair average of 8000 miles. A tire costing $50 in 1914, and giving 4000 miles service, made the tire cost per mile of motor travel one and one-quarter cents. The 1920 price of the same tire was about $70, but the tire gave at least twice the mileage, reducing the tire cost per mile to seven-eighths of one cent, despite the fact the tire cost $30 more. But with the present 20 per cent drop, in addition to the cut made a few months ago, the 1921 tire, giving an average of 8000 miles service, costs no more than the 1914 tire, which gave only half the mileage. This then reduces the cost per mile, per tire, to five-eighths of a cent.

The comparison of mileage costs is

(*Continued on page* 984)

Jordan Prices Down $400 on All Models

CLEVELAND, May 2—Effective today, prices on Jordan cars are reduced $400. The new schedule of prices follows:

	New Price	Former Price
5 passenger touring	$2250	$2650
Roadster	2250	2650
7 passenger touring	2475	2875
4 passenger closed brougham	3300	3700
5 passenger sedan	3300	3700

Speaking of the reductions, President E. S. Jordan said:

"The automobile business is coming back. We are very fortunate in that we have liquidated all our inventory and we are buying and producing on a quantity basis.

"Our production has now reached 100 per cent and the new price will justify itself by doubling our production, thereby greatly reducing our overhead. We find that the purveyors of materials are willing to grant price concessions when a firm order for material is offered to them. The Jordan company always had been in a strong financial condition. In spite of slow production during the winter all obligations were met in a satisfactory manner."

W. D. Riley, sales manager, said salesmen and distributers would be instructed to emphasize that Jordan has made a bonafide revision of prices downward. "Since September, 1920," he said, "it cannot be shown that this company raised prices after announcing cuts."

VICTOR DEFERS PRICE ACTION

SPRINGFIELD, OHIO, May 2—Directors of the Victor Rubber Co. made an inspection of the plant here and were advised by President H. S. Berlin that prospects are encouraging for a busy season. The daily production is 500 tires, which is the normal output of the works. General conditions are excellent, according to Treasurer H. H. Durr. There is a good demand for cord tires, it was stated. All of the present policies of the company were confirmed by the directors at their conference Friday at Hotel Shawnee following the plant inspection. So far no reduction in the price of tires has been announced. Berlin said that some announcement would probably be made soon.

Marmon Cuts Price to New Cost Basis

Reductions Range from $1,015 to $1,400—Look for Business Stimulation

NEW YORK, May 2—Reducing the price of the Marmon 34, seven-passenger, four-passenger, and club roadster cars from $5,000 to $3,985, effective today, is the most important action in the price field that has taken place since the reductions last fall. The Marmon reduction of over $1,000 makes the new price of $3,985 one based on the lower production cost of the next eighteen months, and is a complete reduction rather than a series of minor ones, and as such should have a stabilizing influence. Reductions on the other body models are:

Model	Former Price	New Price
4 and 7 passenger	$5000	$3985
Speedster	5300	4185
Coupe	6150	4875
Sedan	6600	5275
Limousine	6800	5400
Town car	6800	5400

Commenting on the reduction, Vice-President Moskovics said:

"We believe that the spirit of our reduction is in keeping with the demands of the American public and in accord with the spirit of the times. We do not believe that any company can sit tight on its inventories purchased during the period of high prices and assist in starting the prosperity in this country.

"A stand-pat price policy is not in accord with the recent announcement of a 14 per cent reduction in steel.

"Material can now be purchased for less than was the case a year ago. Present inventories are worth only their reproduction value. So we have disregarded prices paid for present inventories and figured instead what materials and labor can be purchased for now or in the immediate future. We believe the public is entitled to purchase its needs at present day valuations and my company is willing to sell its motor cars regardless of the necessary sacrifices.

Increased Buying Expected

"Not only this, but Marmon believes that this radical price reduction will broaden its market four fold and enable it to utilize the tremendously increased manufacturing facilities of its Indianapolis plant."

Marmon has made no changes in discounts to distributers, sub-dealers or direct dealers under the new prices. One reason back of the heavy reduction is that of not making any provision for long trades and thereby encouraging the over-appraising evil at a time when the used car market is heavily overstocked throughout the country. From many parts of the country have come reports of too high appraisal on cars which has brought severe criticism from many distributers handling various lines, and a decisive price reduction should stabilize rather than disturb used car values.

Receiver Is Named for Hartford Parts

Friendly Action Is Undertaken to Permit Company to Continue Operations

HARTFORD, CONN., April 30—Judge Edwin S. Thomas in the United States District Court has granted the application for the appointment of a friendly receivership for the Hartford Automotive Parts Co. so that the assets of the company may be preserved from unfriendly creditors and the company be permitted to secure its finances. R. E. Carpenter, president of the company, and Cyrus C. Chamberlin of Southington, are named as temporary co-receivers. It is anticipated that application will be made shortly to have the receivers permanent.

The company has a factory in Hartford and another in Kalamazoo, and has a large amount of stock on hand and many orders. In the opinion of Peter A. Frasse & Co., who maintain a distributing office in Hartford, the Hartford Automotive Parts Co. could reestablish itself financially if permitted to complete its orders. The Frasse company through its attorney made the application for the receivership.

The receivers have been ordered to file their bonds of $100,000 and they are permitted to conduct the business as long as it can be conducted at a profit. R. E. Carpenter was recently made president of the company, which has been one of the leading manufacturing enterprises of the city. The company some time ago removed to the former Billings & Spencer plant.

URGES AIRCRAFT FOR NAVY

WASHINGTON, April 30—Establishment of a bureau of aeronautics in the Navy Department has been recommended to the Senate in the report of the Senate Naval Affairs Committee. The Keyes bill which the committee favored provides for a central authority with the bureau independent of the other aviation groups of the Government. Passage of the bill is expected at the special session, for nation-wide interest has been aroused by demonstrations of the efficiency of aircraft as naval auxiliaries for offense and defense.

MARATHON TAKES OVER BURLOCK

WAUSAU, WIS., April 30—The Marathon Rubber Products Co. of Wausau, Wis., a new $300,000 corporation, which takes over the plant and business of the defunct Burlock Rubber Co. of Wausau, has resumed the operation of the plant. The officers of the new company are: President, J. H. Elliott; vice-president, F. G. Schneider; secretary, Roy E. Chellis; treasurer, Harold E. Damon. E. B. Helwitz, an expert in rubber manufacture, has been appointed general works manager.

The company begins operations under favorable financial conditions, being free from debt and having from $75,000 to $100,000 worth of raw material on hand, paid for, besides some finished goods. Practically all of the 200 stockholders held shares in the defunct company and pooled their issues to purchase the property for $65,000 in cash at receiver's sale. The old Burlock company was a $250,000 corporation and its liabilities at the time of bankruptcy a month ago were $164,-507.65.

Small Stockholders to Advance $200,000

INDIANAPOLIS, April 29—Steps are to be taken immediately to rehabilitate financially the William Small Co. of this city, automobile manufacturers. At a recent meeting here of the stockholders it was decided to refinance the company immediately. The stockholders, after looking over the plant and seeing what has been done, agreed to subscribe the additional money on one, two, three and four-year notes, non-interest bearing to the extent of $200,000. According to William P. Small, founder of the company, this amount will enable the company to discharge the receiver through payment in full of the creditors and will put the plant back on its feet.

The stockholders, through the directors, declared, following the meeting, that the company was solvent and all it needed was some emergency money. Production has never been stopped and will be increased as the sales department is developed. The new directors elected at the meeting are William P. Small, Walter G. Todd, John Rau, Elmer E. Stout, J. F. C. Martin, E. L. Jacoby, T. A. Lavelle, D. L. Fryer, Carl Rost, W. A. Moore and D. H. Lockwood. Small, Todd and Martin were re-elected. The number of directors was increased from five to eleven.

Miniger to Continue As Auto-Lite President

TOLEDO, April 30—The election of C. O. Miniger as president of the United States Light & Heat Corp. has given rise to the belief that he had resigned as president of the Electric Auto-Lite Corp. On the contrary, Miniger retains his position at the head of the Auto-Lite, and D. H. Kelly, who has accepted the vice-presidency of the United States Light & Heat Corp., will take active charge of that plant at Niagara Falls. Kelly formerly was with Miniger at the Toledo plant.

TO BUILD NEW SNOW PLOW

MILWAUKEE, April 30—The Milwaukee Snow Conveying Co. has been incorporated with a capital stock of $25,000 to develop an invention of A. F. Krueger. This consists of a high speed rotary snow plow mounted on motor truck chassis. It plows a swath 10½ ft. wide, throwing the snow from 20 to 35 ft. to one side.

Ruggles Organizes New Truck Company

Will Start Manufacture with Two Models in Saginaw—Has $2,000,000 Capital

SAGINAW, MICH., April 28—Following the completion of the organization and the election of officers, announcement was made here to-day of the formation of the new Ruggles Motor Truck Co., with a capitalization of $2,-000,000, to manufacture a light truck and two-ton truck, which will be followed ultimately by a complete line. Frank W. Ruggles, former president and general manager of the Republic Motor Truck Co., is president of the new company.

Ruggles is recognized as a leader in the motor truck industry. Under his guidance the Republic company of Alma, Mich., grew to be the largest motor truck manufacturer in the world. The new company has ample financial backing, and, with Ruggles' truck manufacturing knowledge and experience, the new Saginaw enterprise looms as a new giant in the truck field. Production on the models will start immediately and the first truck models it is expected will be ready for showing in July.

The officers and directors elected are as follows: Frank W. Ruggles, president; W. J. Wickes, vice-president; Ezra L. Smith, secretary; Walter C. Hill, treasurer; Charles T. Kerry, assistant treasurer; John F. O'Keefe, counsel. The directors are Ruggles, Wickes, Smith, Hill, Kerry, O'Keefe, Benton Hanchett, Julius B. Kirby, H. T. Robinson, Otto L. Dittmar, John J. Thorne and Harry H. Price.

Connersville Factories Find Business Growing

CONNERSVILLE, IND., April 29—There is no longer question that business is coming back in this automotive center. The Rex Mfg. Co., the pioneer winter-top manufacturers, was nearly out of business sixty days ago, but the orders are weekly increasing. The engineering department has been exceedingly busy the past thirty days. Then will come the production rush. This company has now taken up in earnest the California top and the demand for it equals the old standard top.

The blower companies that produce more than 50 per cent of the world's rotary blowers, gas exhausters, etc., are holding to about a 33⅓ per cent basis. President John T. Wilkin of the Connersville company will visit Europe in June in the interest of his company.

The Wainwright Engineering Corp., makers of pistons, rings and cylinders, some two years ago saw the future in replacement pistons in rebored cylinders and now have the entire United States covered through the jobbing trade. It is the busiest shop here.

Farmer Buyers Back in Columbus Market

Good Crop Prospects Bring Return of Rural Business—Unemployment Lessens

COLUMBUS, April 30—With the arrival of better weather, followed by a period of heavy rains and changeable conditions, demand for automobiles in Columbus and central Ohio territory is showing quite an increase. All of the dealers located in Columbus report a gradual expansion in their business with much brighter prospects for the future. Business is more settled than formerly and it is the consensus of opinion that the worst of the slump is over and that there will be a gradual increase in business during the coming two months.

All lines of cars are selling better than was the case during the month of March and early in April. This applies equally to the higher priced cars as well as to the medium priced and lower priced machines. One of the best features of the trade is the fact that rural dealers are now experiencing better business as there is more buying among the farming population. With prospects for good crops this year, the farmers are now coming into the market. All rural dealers are more optimistic, and the remainder of the year is expected to show good results.

City dealers are also having a better run of business as industrial conditions are righting themselves slowly. There is not quite as large an unemployment problem as formerly and this is having a good effect on every line of business, the selling of automobiles included. It is found that not as much work is required now in the sale of an automobile as formerly, people are inclined to go ahead and are not playing a waiting game as was the case several weeks ago.

The enclosed car is still one of the most popular types of passenger vehicles. All of the local dealers report a big increase in the sale of enclosed cars, while touring cars are not showing as well as the enclosed models. Runabouts still continue rather popular, as is shown by an analysis of the demand.

With business slowly improving in every line and also because of the fact that Columbus was not as badly hit as some other cities by the depression, the automobile industry is now getting on its feet with a vengeance. Dealers who have been somewhat pessimistic during the early parts of the year are coming out and their sales forces are hustling for business. These things have caused a better feeling in automobile circles generally.

SNOW HITS DES MOINES TRADE

DES MOINES, April 29—The first half of April has been a disappointment to the motor car dealers of central Iowa and has not produced the business that had been expected after the March spurt. Des Moines distributors almost without exception declare that April business for the first fifteen days was considerably behind the pace set by March. The falling off is largely attributed to weather conditions as a greater part of the month so far has been rainy and cold. Last week it started to rain early in the week and kept it up until Friday night when the rain turned to snow, and Saturday Des Moines had the heaviest snowfall of the winter. Nine inches of snow fell Friday night and Saturday.

G.M.C. Makes Changes in Unit Management

NEW YORK, May 3—General Motors Corp. announces that John L. Pratt has been appointed general manager of the accessory division of the corporation, with headquarters in New York City. He relieves Alfred P. Sloan, Jr., vice-president of the corporation, of direct supervision over the activities of the accessory units as follows:

Hyatt Roller Bearing	New Departure Mfg.
Remy Electric	United Motors Service
Jaxon Steel Products	Delco Light
Dayton Eng'r'g Laboratories	Klaxon
Harrison Radiator	Champion Ignition
Lancaster Steel Products	Frigidaire
	Dayton Wright

Pratt was formerly special assistant to the president of the corporation and chairman of both the inventories committee and the appropriations committee. Prior to coming with General Motors he was director of the Motors Development Division of the DuPont Co. His position now is similar to that held by Sloan under the Durant regime.

E. F. Johnson has been appointed general manager of the inter-company parts division of the corporation, with headquarters at Detroit. Johnson assumes direct supervision over the activities of the inter-company units as follows:

Saginaw Parts	Canadian Products
Saginaw Malleable Iron	Northway Motor
Central Foundry	Central Forge
Michigan Crankshaft	Central Axle
Central Gear	Lansing Axle
Saginaw Products	Muncie Parts
	Muncie Products

KOKOMO NEARS 1000 A DAY

INDIANAPOLIS, April 29—Announcement was made yesterday by Randolph Mitchell, assistant secretary of the Kokomo Rubber Co., that the record production for one day since the recent resumption of operation was 998 tires, while each day during the past week averaged 950 tires, and they expect soon to produce 1000 tires a day.

REVERE TO BE REORGANIZED

FORT WAYNE, IND., May 2—A new organization to take over the plant of the Revere Motor Car Corp. of Logansport, Ind., is now apparently certain. The plan is for the organization of a company with a capital stock of $500,000 among the old stockholders. This plan is meeting with approval.

Perrin to Direct Stevens-Duryea Work

Noted Designer and Engineer Is Chosen Manufacturing Executive of Company

CHICOPEE FALLS, MASS., May 2—John G. Perrin, one of the foremost engineers and manufacturers in the automotive industry, has been elected a director and vice-president of Stevens-Duryea, Inc., in charge of engineering and manufacturing. He has been serving for several months in a consulting capacity and now has consented to become permanently identified with the company.

The business career of Perrin was started as a draftsman in the Lozier bicycle factory in Toledo. He soon evinced a desire to learn the practical side of shop practice and apprenticed himself as a toolmaker. He filled various positions with the Lozier company and at one time was in charge of the plant at Thompsonville, Conn., where its screw machine work was done.

In the early days the Lozier company built bicycles and marine engines, but Perrin's inclination was toward motor cars. He aspired to design a fine car and in preparation for this work made an intimate study of all foreign cars. He went so far as to spend six months in the repair shops of the larger New York companies selling foreign automobiles.

He then designed the first Lozier car, but as the company was not ready to take up its manufacture he went for a short time to the Waverly Electric Car Co. at Indianapolis and designed for it a new model electric. The Lozier company soon recalled him, however, as its chief engineer. He later was made vice-president in charge of engineering and production.

When the Lozier company went out of business, Perrin became chief engineer for the Timken Detroit Axle Co. During the war he served in various capacities and finally was called upon to help the Willys-Overland, Ltd., of Toronto to fill a contract for Sunbeam airplane motors. Under his direction the company reached a production of five complete 8-cylinder Sunbeam engines a day before the war ended.

Perrin left Overland last fall to devote his time to personal interests. He had made definite plans for the future, but became interested in Stevens-Duryea and now has cast his lot definitely with that company.

DELIVERIES HANDICAP TRADE

TORONTO, April 29—Much more grousing is heard in the trade regarding deliveries than sales. Indeed, a recent canvass showed that almost without exception distributors and dealers have been agreeably surprised with the "comeback" of business, several leading companies reporting better business than last year—"every month so far ahead of corresponding month of 1920."

Cotton Financing Cuts Car Credits

New Orleans Dealers Feel New Stringency as Crop Selling Plans Materialize

NEW ORLEANS, May 1—Somewhat improved conditions in the sugar market; the working out of cooperative plans for selling the $18,000,000 to $20,000,000 worth of cotton now held in warehouses in this part of the South; heavy planting of crops other than cotton and sugar, and the general feeling that Louisiana, Mississippi, Texas and Alabama have suffered less from the recent business depression than most other sections of the country, helped to keep the retail automotive business in New Orleans for April up to the good figure set in March.

Sales of standard cars were about 80 per cent of those of eighteen months ago; sales of the higher priced cars about 65 to 70 per cent, while, like Abou Ben Adhem, the Fords "led all the rest," with sales of between 95 and 97 per cent normal. There is no denying that Ford dealers, combined with Ford price-cuts, have "put one over" in the automotive industry in this part of the South. Scores, probably hundreds, of men in Louisiana who had intended to buy higher priced cars on time payments are driving Fords—the little sedan especially having been the hit of the season—for which they have paid in full about what they would have had to pay for the first payment on a more expensive car.

Reports from the country, and especially from the city centers of distribution outside New Orleans and Jackson, indicate that the dealers in those cities and in the country have not fared so well as their New Orleans brethren. The reason seems to be that the city dealer learned a rather expensive lesson on the used car during the war period and is cutting his allowances for used cars down to a minimum or not taking them at all, while the country and small-city dealer is still over-stocking himself with used cars, and is trying to get rid of some of them, to the exclusion of his new car business.

Used Cars Pile Up

This condition also complicates the used car situation, and the purchase of a car has become a matter of haggling on both sides, concessions on the part of the dealer, and a stiff position held by the prospective purchaser, since this is essentially a buyers' market, as it has been for several months. The banks have been calling on the dealers for close margins on their loans, and—despite the impression the bankers are trying to make, that they are "helping the automotive industry"—renewals are difficult, and the majority of the banks look with anything but favor on automobile paper. This being the case, the dealer who is loaded up on used cars simply HAS TO MOVE HIS STOCK.

Obviously this is a situation which is full of dynamite for the industry, but it has worked out in favor of the city dealer as against his country brother, because the city dealer, having taken in used cars at a minimum price and still held his figures on the new cars he has sold to these used car owners, is in a better position to put out "bargains" in used cars, and even to reduce prices under those of his bargain sales, than is the country dealer. One city dealer estimated to the writer that 65 per cent of the automobile dealers in Louisiana outside New Orleans are to-day overstocked on used cars.

St. Louis Makes Ready for Big Buying Period

ST. LOUIS, April 29—A general survey of retail trade conditions in this city reveals the fact that the sales and and trend of indications of the past two months are leading dealers throughout the entire territory toward the expansion of their sales forces and the perfection of systems for the efficient handling of what they believe will be a great buying period. In preparation for the expected prosperity many local firms are holding special training schools for their new and veteran salesmen; many new service stations and gasoline filling stations are being erected, and many innovations are being intrdouced by various dealers.

Robert E. Lee, secretary of the St. Louis Automobile Dealers' & Manufacturers' Association, declared that the past seven weeks have given sufficient indication of a marked improvement in the motor car business.

"Many firms in this city," he said, "have done a larger business in April than they did in April of last year. And the sales are not confined to the small and inexpensive cars, many of the larger and more costly machines being greatly in demand. The banks are in a splendid condition. In fact, better than they have been for some time."

IMMEL PLANT TO BE SOLD

COLUMBUS, April 29—Robert H. Schryver, receiver for the Immel Co., makers of automobile bodies, has applied to the courts for authority to sell the plant and all assets. Schryver states in his petition that there are no orders on which work can be started. The plant has been closed for several months and the organization has been disrupted as a consequence. It is believed that the sale will occur about June 1.

DU PONT CUTS VARNISH PRICE

WILMINGTON, DEL., May 2—Substantial reductions on all lines of varnishes have been made by the E. I. du Pont de Nemours & Co., Inc., effective to-day. The reductions range from 25 cents a gallon on the lower grades to $1 a gallon on the high-class product. The company declares the reductions are warranted by the reduced cost of production and by the increased volume of sales.

April Selling Drop Mystifies Atlanta

Dealers Look to May to Bring Renewed Buying—Truck Sales Low

ATLANTA, April 30—Dealers and distributers in the Atlanta territory are at a loss to understand just what has happened to slow up automobile sales the past three or four weeks. There is no question but that sales have fallen off and even the most optimistic distributer will admit it, but none of them seem to exactly understand its cause. During and immediately following the Atlanta automobile show the early part of March sales were unusually good considering the period of depression the industry had just passed through, but early in April the Atlanta dealers began to note a decline in sales.

This has continued almost the entire month, and while April sales will compare favorably with March, considering the fact that the show was held during the latter month, April sales should have greatly exceeded March, in the opinion of most of the dealers. Warm weather has come in earnest and generally early spring witnesses an increased demand for motor cars. As yet, however, it is not noted in the Atlanta territory. The dealers are still optimistic enough as regards the future, and confidently believe that May will note a steady increase in the volume of sales.

Truck sales are at a very low ebb and have been for several months. While there may be some improvement in truck business the next month or two no great activity in that regard is expected until all lines of business in this section return to something like normal. Conditions are very bad in the lumber industry and the agricultural industry, two big users of motor trucks and tractors in the Southern field. Until conditions materially improve in these and other important industries of the South, there can be no great demand.

Saxon Sells Service on All Former Models

DETROIT, April 30—Through a deal consummated with the Saxon Service Corp. the Saxon Motor Car Co. relinquishes parts service rights on all Saxon cars running up to the time the Saxon Duplex was put on the market, in consideration of $550,000. The Saxon Motor Car Corp. has $500,000 outstanding bank loans of which it will pay $400,000 and also $85,000 to merchandise creditors.

This deal will permit the Saxon company to start production of its new model with the Gray engine immediately, President C. A. Pfeffer said to-day. Production on the new model is not expected to reach capacity output of 100 daily for some time. It is understood that the Saxon Service Corp. is controlled by Maurice Rothchild of Chicago.

British Competing for Japanese Sales

American Cars Dominating Market—Local Advantages of Both Cars Compared

SEATTLE, April 29—Of the 9000 automobiles now in use in Japan, fully 75 per cent are of American manufacture, in contrast to the situation before the war when British and Continental cars dominated the market. It is reported that British cars are again arriving (in very few numbers, however) in Japan and in other Far Eastern countries.

The average type of car used in Japan is medium-priced, open model, retailing on the market for from 7000 to 8000 yen (yen 50 cents normally).

A Japanese publication just received here from the Orient says that the typical British export model is a four-cylinder job, having a 15 horsepower, and actually developing 30. The L-head system survives. Ignition is by high-tension magneto, and the carbureter is conventional, with gravity feed from the gasoline tank, which is usually located in the dash. Lubrication is by force feed, with pump, and the cooling system is conventional.

The engine, on the whole, is of fairly clean design and very good workmanship, and accessibility is a feature. A cone clutch is used, and the transmission, which is placed amidships, provides four forward speeds and one reverse. Final drive is by propeller shaft to a bevel-geared rear axle. A great many cars of this type use an under-slung worm type of final drive. In either case a torque tube is employed, and the rear springs are cantilevers. The foot brake operates on the propeller shaft and the hand brake actuates expanding shoes in the rear wheel drums. The front springs are semi-elliptic and the steering is conventional.

American Type Most Powerful

The corresponding American type is described as a light six, rated at about 25 horsepower and actually developing about 50. The engine is of high-speed design. It is a block casting, with three bearings and all valves are on the same side. Ignition is furnished from the battery of the starting and lighting system, but many American manufacturers equip all cars for export with a high-tension magneto in addition. The carburetor incorporates some device for pre-heating the fuel, and feed is through a vacuum tank located under the engine hood, the gasoline tank being between the frame members at the rear of the chassis.

The cooling and lubrication systems are similar to those employed on the British model. The clutch is a dry-plate disk, and the transmission, which provides three forward speeds and a reverse, is a unit with the engine. Drive is by open propeller shaft through spiral bevel gears to the rear axle, both drive and torque being taken by the rear springs, which are semi-elliptic, very long, almost flat, and shackled at one end only. The rear springs are underslung from the rear axle. Both hand and foot brakes operate on rear wheel drums, the former expanding and the latter contracting. The front springs and steering system are similar to the English model.

Mechanically, the two models are described by the Japanese critic as quite different. The American is given credit for being far more powerful, and its flexible engine and low gearing provide a wide range of speeds in high gear. The British car is pictured as the better piece of machinery.

Exchange Rates Hurt South American Sales

BUENOS AIRES, April 1 (*By Mail*)—With the rate of exchange between Argentina and the United States at 131 per cent dealers in this country have been obliged to sell many cars at a loss partly due to the impossibility of competing with European cars that are now entering the market. Several makes of American cars have sold well notwithstanding this handicap. Many dealers of American cars are carrying large unsold stocks in their agencies and in the custom house as well.

The accessory business has suffered severely, due to the very large stocks on hand of practically all kinds of accessories. Some are trying to sell these at any price and there is good hope that the situation will soon improve and approach normal.

The sale of trucks in most of the South American countries is in its infancy but the conviction is general that there will be little extension of railway lines and that the building of highways and installing motor truck service furnishes a more flexible and cheaper scheme of transportation. In all countries of South America this phase of truck development is one of the most attractive. To-day there is in Argentina a total lack of good highways and truck use is largely confined to the cities and some of the larger farmers. Road building sentiment is on the increase. What is needed is some road promotion organization that will spread good roads propaganda.

The sale of passenger car tires has not diminished in cities like Buenos Aires due to the large number of cars used as taxis in the summer months of November, December, January and February. European competition is intense and some of them are offering their goods at very low prices.

PANAMA TO BUILD ROADS

NEW ORLEANS, April 30—The Republic of Panama has commenced work on a nation-wide system of good roads, according to announcement by the consul of that country in New Orleans. The plan is to connect Panama City, the national capital, with the capital of each State of the republic by an automobile road. "Good roads throughout the country will increase production and raise the buying power of the people."

Australia Suffers Wave of Depression

Little Buying Looked for Inside of Year—Automobile Stocks Six Months Ahead

SYDNEY, AUSTRALIA, April 11 (*By Mail*)—The wave of depression which swept across the United States in June, 1920, has reached Australia, which is now in the throes of the worst trade depression the Commonwealth has known. This general trade depression is bringing in its train a large army of the unemployed. It will be twelve months before this country is in condition to buy automobiles and before trade is back to where it was a year ago. Practically every automobile dealer in Australia is loaded too heavily with cars, and a conservative estimate shows that there is a six months' supply on the dealers' hands, which is too heavy for an industrial condition such as exists to-day.

The bottom fell out of the used car market and good used cars can now be purchased at one-third to two-thirds of what they sold for a few months previously.

Although Australia had a good wool clip there is not much market for wool. The wheat crop was a record one, but before the crop was harvested overseas markets had fallen, and to-day the Australian farmer is much like the American farmer, very short of cash, and not a potential buying factor for the next few months.

Another important factor entering into the automobile situation is the difficulty of New York and London selling bank drafts. Australian bank credits held by Australian bankers in London are exhausted. Consequently the only way to do business is a letter of credit of 30, 60 or 90 days' maturity, and the banks are very reluctant to issue such.

INDIA FIELD FOR TANKS

WASHINGTON, April 29—Consul Weddel, in a report to the Bureau of Foreign and Domestic Commerce, expresses the belief that a growing market for portable tanks could be developed in Calcutta, India, and surrounding district, if properly introduced. At present, he says, gasoline in Calcutta is distributed by the oil companies to dealers by means of small handcarts with a capacity varying from 10 to 30 two-gallon tins, drawn by coolies.

SOUTH AFRICA IMPORTS HIGH

WASHINGTON, April 30—According to American Trade Commissioner Stevenson of Johannesburg, South Africa, official figures for the first 11 months of 1920 show imports of passenger cars into South Africa numbering 9150, valued at $18,378,765 at the normal rate of exchange. Lorries to the number of 239, valued at $601,205, were imported during the year.

Collins to Build New High Grade Car

Durant Stockholder But Company Will Be Independent—Merger Story Denied

NEW YORK, May 2—The following statement in reference to the future plans of R. H. Collins, whose resignation as president and general manager of the Cadillac Motor Car Co. was accepted last week, was authorized to-day:

"The Collins Motor Car Co., a Michigan corporation with a capital of $10,000,000, is being organized to manufacture a high grade car bearing the name Collins. The car will be ready for the inspection of the public Jan. 1, next. Collins, with a few of his former associates and personal friends, will control the company. The plant will be located in Detroit."

This statement, prepared in the New York headquarters of W. C. Durant, shows that there has been a sudden change in the original plans under which Collins was to head the Michigan subsidiary of Durant Motors, Inc., which was to be known as the Durant-Collins Co. There will be a Durant-Michigan company, but it will produce the Durant four-cylinder car. The original plan called for the production of a high grade car to be known as the Collins, and this part of the program has not been abandoned, although the car will be made by an independent company. Durant will be a large stockholder in the Collins company.

While Durant will be intimately associated with Collins in the new company, the corporation will not be, strictly speaking, a subsidiary of Durant Motors, although the business relationship between the two is expected to be close. No details of the corporation's plans are available beyond those contained in the statement. This would indicate that there is no basis for the report from Cleveland that the company would locate a plant in that city.

Plant Location Indefinite

It is understood that the Cleveland story, printed under scare heads in the newspapers of that city, was given publicity under a prearranged plan whereby it was to be printed as soon as acceptance of Collins' resignation from the General Motors Corp. was announced. This was done without consideration of possible changes in the plans.

The program, as it was understood in Cleveland, called for the location there of a large factory by the Durant-Collins Motor Corp. According to the Cleveland story, the car which it was proposed to manufacture there would compete with the Buick.

No details in regard to the Durant car have been made public, but it has been announced it would sell for less than $1000 and several officers prominent in the Chevrolet company have joined the Durant organization. The latest to go with him was M. J. Lahey, who has retired as sales manager of the Chevrolet Motor Co. of New York to become sales manager of the Durant Motors Co. of New York, which recently acquired the Goodyear plant in Long Island City. Lahey's successor has not been appointed by the Chevrolet company.

There was a sharp advance to-day in Pierce-Arrow and Studebaker stock on the stock exchange on reports that Durant was planning a merger of his company with them. It was emphatically denied at Durant's office that he had any interest whatsoever in Pierce-Arrow. So far as Studebaker is concerned, he recently has become a large stockholder in that company, but so far as can be learned there is no probability of it coming under his control.

Charles F. U. Kelly Now with Quaker Tires

PHILADELPHIA, May 2—At a meeting of the directors at the office of the Quaker City Rubber Co., Philadelphia, Pa., Charles F. U. Kelly was elected director of sales of the tire division of the company, which also manufactures a full line of mechanical rubber goods.

Mr. Kelly has been engaged in directing tire sales practically all his life. He began selling tires to the bicycle industry in 1893 and with the exception of a much needed rest during the past year has been continuously engaged in tire selling. His experience is far reaching, having been associated in the past with such concerns as Goodrich, Pennsylvania, Racine, Continental and Lee.

Sales offices have been opened at 1664 Broadway under the name of the Quaker City Rubber Co., Tire Sales Division, from which address Mr. Kelly will conduct the selling campaign.

Mr. A. H. Thomas, formerly associated with Mr. Kelly, has again returned to his old employer and will assist in the promotion and sale of the Quaker City tire products.

NASH OUTPUT 79 PER CENT

KENOSHA, WIS., May 2—The plant of the Nash Motors Co. is operating at 79 per cent of normal and the new factory in Milwaukee is increasing production daily. Orders for May show a healthy increase over April. Low ebb in Nash production was reached in December with a total of 714 cars. The tide began to turn in January and production in March had jumped to 2081. The production schedule for April called for 2311.

CANADIAN FORD RESUMES

DETROIT, May 2—The Ford Motor Co. of Canada has resumed full time operations with a normal force of 2900 men, according to Wallace R. Campbell, secretary of the company. The plant has been closed on Fridays and Saturdays each week for the last six months.

Eaton to Push Plans to Restore Standard

Resigns as Joint-Receiver of Company to Further Reorganization Work

CLEVELAND, May 2—J. O. Eaton, who has for some months been a joint receiver of the Standard Parts Co. with Frank A. Scott, yesterday presented his resignation to Federal Judge D. C. Westenhaver. It was stated that Eaton resigned to devote himself to bringing about a reorganization of the big $20,000,000 automobile parts concern that has been in the hands of a receiver since last September. Eaton will cooperate with the creditors' committee, which has presented a plan for placing the corporation on a permanent business basis.

At the same time it was learned that within the next ten days letters endorsing the creditors' plan probably will go to stockholders from their special committee that had been named to consider the proposal. From now on special effort will be made to complete the reorganization. Prompt action is regarded as highly necessary, in view of the satisfactory conditions in the automobile trade and the demand for products made by the corporation.

Cyrus S. Eaton of Otis & Co., originator of the creditors' plan, has issued a statement to stockholders, in which he urges them to support the latest proposal. In his address he first calls attention to the fact that a distinction between creditors and stockholders must be borne in mind. The creditors loaned to the company money which became due last September, and the stockholders contributed money for an indefinite period in the hope of obtaining profits from the business; so that they assumed the risks of the enterprise.

Creditors Suspend Payments

The new financing plan which has been formulated provides for the formation of a new company to take over all the properties of the old corporation and for the issuance of $6,500,000 of 8 per cent first mortgage notes, maturing Jan. 1, 1924, and of 100,000 shares of no par common stock, all of this to be turned over to the creditors in payment of the company's debt to them. Inasmuch as the company's total outstanding debt is $10,000,000, this means that the creditors thus suspend collection of 65 per cent of their claims for the period of three years and accept stock in the company for the remainder. The plan also provides that stockholders in the old company are privileged to purchase from the creditors' stock of the new company.

"The plan involves a sacrifice by the creditors," said Eaton. "But an overwhelming number of creditors have been persuaded to accept it. If this plan miscarries no one is prepared to suggest an alternative."

Goodrich Sets Pace in Tire Price Cuts

Increased Mileage Makes Tires Cheapest in History—Other Companies Reduce

(*Continued from page* 978)

even more striking if made with 1910 tire mileages, and tire prices.

In 1910 a 34 x 4 tire cost about $53.40. The 1920 price for the same tire was $40.10, while the price up to May 2 has been $36.10. The Goodrich 20 per cent cut brings this tire down to $28.88, which means a difference or saving of $24.52 per tire, as compared to 1910 prices, and yet the tire of to-day gives three times the mileage given by the tire built in 1910. Figuring on this basis, the 34 x 4 tire to-day gives three times the 1910 mileage and costs more than 40 per cent less.

W. O. Rutherford, vice-president of Goodrich, in charge of sales, in discussing the company's announced tire price reduction, states:

"I presume that the reduction in tire prices was not unexpected by the motoring public. But it is safe to say that it is a much greater reduction than the consumer anticipated. The only question is whether or not it is too low.

"Putting business on a normal basis is not a job for one man or one concern. The public can do this better than any other force, and it will find both manufacturers and dealers more than ready to co-operate. Conditions in the automotive industry seem to be much better, and the outlook much brighter, and of course this will be reflected in the tire industry. Fair wages, honest products, right prices and a square deal all around are what will give producer, distributor and public real confidence. Recognizing this, we put our prices at the point we have announced."

Mason Makes Price Cut

AKRON, May 2—Mason Tire & Rubber Co. has reduced the prices of heavy duty cord tires 20 per cent and other prices in proportion. Preferred and common stock of the Mason Rubber Plantation Co. will be acquired by the Mason Tire & Rubber Co. of Kent, according to notices being sent to all stockholders. The exchange will be made on the basis of preferred stock share for share plus the accumulated dividends to July 1, and one share of Mason Tire & Rubber series "B" no par common stock for two shares of Plantation common, fractional shares to be adjusted on the basis of $20 per share for the Mason Tire & Rubber stock.

Goodyear Doubles March Sales

AKRON, May 2—Sales of the Goodyear Tire & Rubber Co. for April represented an increase of 125 per cent over March sales, with prospects bright for a continued increase in dealer and automobile manufacturers tire specifications for May, officials announce. The company had anticipated a 75 per cent increase in April sales and, working on this basis, added 1200 men, increasing production to 17,000 tires a day. But with the steady pouring in of orders it was necessary to put on several thousand more men, to reinstate the third or midnight factory shift and to speed production to 20,000 tires a day.

Firestone on 20,000 a Day

AKRON, May 2—The Firestone Tire & Rubber Co. to-day advanced to a production of 20,000 tires a day, which is equal to the company's normal production of last year, and is above the Firestone pre-war production record. Firestone during April increased production from 10,000 to 15,000 tires a day, putting on several thousand employees.

Increased tire specifications from automobile manufacturers and heavy demand for tires from all dealers necessitate the big jump in production, officials state.

President Harvey S. Firestone announces, in connection with the re-employment of many men, that all employees of the company now are stockholders. As far as is known Firestone thus becomes the only large concern in the country with 100 per cent of its employees owning stock in the company.

Cotton Financing Cuts Car Credits

(*Continued from page* 981)

While the cotton producers have not sold their cotton, both they and the bankers are working together on plans to sell it through cooperative methods, and by the aid of the Edge Bank in New Orleans, to the mills of Middle Europe. To do this the bankers have agreed to finance the cotton planters, but to do this financing they must have money, and the first man to fall under this search for money is the automobile distributer and dealer.

Before the automobile industry of the South can be put back on its feet firmly, there must be a break in this chain, so that fresh money can come in. The financing of the crops is now the vital issue in the territory around New Orleans, and while the automotive industry is a vital factor in the production and movement of those crops, it appears to be in the position of having to wait for a real revival of business until the crops are in and sold.

United States Cuts Price

NEW YORK, May 4—A general reduction in prices on tires has been made by the United States Rubber Co., which will become effective at once. The extent of the cut and its application to the different tire products is now being determined at the factory.

Pennsylvania Prices Down

JEANNETTE, PA., May 2—Pennsylvania Rubber Co. has reduced prices on all tires and tubes 20 per cent, effective today.

Commission Declines Rail Rate Change

Lower Charges on Shipments to Intermediary Points Are Refused

NEW YORK, May 4—In a decision of great importance to passenger car and motor truck manufacturers and to dealers on the Pacific Coast, the Interstate Commerce Commission has dismissed the complaint of the Intermediate Rate Association, which sought to require lower freight rates to intermediate points than to Pacific Coast points on shipments from the East.

This case is the latest development in the long debated question of how to adjust transcontinental rates so that railroads may fairly meet water competition. In this instance the carriers proposed an adjustment, one feature of which was to cancel the special (or so-called commodity rates) on passenger cars and motor trucks in carloads and apply on such shipments instead the class rates. This would also have increased the carload minima.

Carriers pointed particularly to the fact that class rates apply on such shipments generally in all other territories. The examiner condemned the class rates as too high for the long overland haul and suggested a scale that would have resulted in about the same rates on automobile shipments under class rates as now apply under the commodity rates, but these charges are not included in the final order.

The proposed readjustment would have affected Eastern shipping interests generally, and the case attracted wide attention and many protests. The proposed cancellation of automobile and truck rates became known through a report submitted by the railroads as to the commission about a year ago, as a basis for meeting the complaint of the Intermediate Rate Association. The National Automobile Chamber of Commerce at once intervened, engaged counsel, and with the assistance and cooperation of members and Pacific Coast dealers gathered data, submitted evidence at the hearing in New York, May 5, 1920, and final argument before the commission at Washington, Dec. 3, 1920.

The N. A. C. C. was able to show that no traffic, certainly none of like character, moves in as great quantity as motor cars; that in 1919 shipments amounted to 31,500 carloads, the total freight on which was $15,000,000, and that the proposed rate adjustment would have added $3,000,000 to this amount through increased freight charges.

RESERVE BANK LOWERS RATE

NEW YORK, MAY 5—The Federal Reserve Bank of New York announced yesterday a reduction in its rediscount rate on commercial paper from 7 per cent to 6½ per cent. The rate has been at 7 per cent since June 1, 1920.

Mellon Proposes New Motor Taxes

Believe Intelligent Tax Revision Will Encourage Production—Hearings Next Week

(*Continued from page* 976)

only hope of effective relief from the tax burden."

Emphasis was given to the fact than "an intelligent revision of these taxes should encourage production and in the long run increase rather than diminish revenues."

The Senate Finance Committee will open hearings on internal revenue revision next week. Witnesses will be asked to express their opinion of the proposed sales tax and other propositions, including the Treasury plan. The unmistakable hostility to a general sales tax, as revealed in the Mellon letter, will have a tendency to block the bill in Congress. It is understood that the Treasury would not speak without the consent of the President and the Chief Executive could not logically, at least, favor a proposal which his financial advisors had opposed.

The testimony taken at the Senate hearings will be forwarded to the House Committee on Ways and Means to save time. This departure will not detract from the importance of fiscal legislation originating in the House, but is adopted purely in the interests of expediency. It is quite likely that the tax committee of the N. A. C. C. will be among the first representatives of industry to be called.

Associations Prepare to Urge Tax Reform

NEW YORK, May 5—Presentation of its taxation program will be made before the Senate Finance Committee next Tuesday or Wednesday by the National Automobile Chamber of Commerce. The hearing has been granted earlier than had been expected and only a half hour will be given for presentation of motor vehicle manufacturers' arguments.

Charts will be used to illustrate to the Senators the heavy burden of taxation already borne by the industry and to demonstrate that additional imposts would be an injustice.

The taxation committee, headed by C. C. Hanch, is in session in Detroit in connection with the monthly meeting of directors of the organizaton and is working out in detail the plan for presentation to the committee. The arguments will be made by Roy D. Chapin and George N. Graham.

Recommendation of Secretary of the Treasury Mellon that a Federal license fee be imposed on automobiles as a means of providing additional revenue probably will result in a recasting of the N. A. C. C. argument. It has been contended that the industry now pays more than its share of taxes and it will be argued that a further Federal tax would be distinctly unfair.

The National Automobile Dealers Association, through C. A. Vane, its general counsel, has been assured by the Senate Finance Committee that it will be granted a hearing on the excise tax provision of the present revenue law. The date for this hearing has not been set, but it will not be simultaneous with that of the N. A. C. C.

Directors of the Motor and Accessory Manufacturers Association in session here to-day will determine whether that branch of the industry will ask a special hearing on taxation.

Application for a hearing already has been made by the Rubber Association of America and its program will be similar to that of the N. A. C. C.

Townsend Bill Hearings to Begin Week of May 8

WASHINGTON, May 3 — Arrangements have been made for hearings on the Townsend Highway bill beginning next week, before the Senate Committee on Postoffices and Post roads. Farmers' organizations and certain groups of highway officials have announced that they will fight the Townsend bill both in committee and on the floor. The fact that President Harding has approved the principles contained in the proposed measure, which was designed after his suggestions were received by Congess, is expected to have a great influence in securing favorable action in the Senate and House.

The American Association of Highway Officials has submitted another plan of highway legislation differing from the Townsend bill in that it does not call for Federal Highway Commission appropriations and adopts another formula of distribution of Federal funds. In other respects, every point contained in the highway organization's bill is carried in the Townsend measure, indicating that they will not have many strong points for argument against the bill. The Highway Commission's measure provides for distribution of at least 60 per cent of Federal funds for the development and maintenance of highways of inter-state importance and the balance on roads of State importance.

The Chamber of Commerce of the United States, at its annual meeting in Atlantic City last week, endorsed the principles contained in the Townsend bill, Senator Townsend expects to conclude the hearings and report the measure to the Senate before June 1.

MEXICO INCREASES TIRE DUTY

WASHINGTON, May 3—According to a cablegram from Consul Cornelius Ferris, Jr., Mexico City, under date of April 30, a decree promulgated April 19, effective April 23, increased the Mexican duty on rubber tires for automobiles from 1 peso (50c.) per gross kilo to 1.50 peso (75c) per gross kilo of 2.2 pounds, and on rubber tires for motor trucks from .50 peso (25c.) to .75 peso (37¼c.) per gross kilo.

Anti-Dumping Change Makes Mellon Judge

Senate Would Bestow Power Upon Treasury Head to Apply Special Duties

WASHINGTON, May 4—While no specific provision has been made to cover the reimportation of motor trucks or war supplies in the anti-dumping bill, Senate leaders believe that this unfair competition may be checked by imposing the dumping duties upon merchandise in cases in which the Secretary of the Treasury, after due investigation, has instructed the appraising officers to apply the anti-dumping provision.

The Senate to-day took up the consideration of the bill as reported by the Senate Finance Committee. This committee reported that it remains for the secretary to determine that the importation of dutiable or free foreign merchandise is injuring or is likely to injure an industry in this country, or is likely to be sold here or elsewhere at less than its fair value.

The situation is not entirely satisfactory to the automotive industry, which had been assured by Senator Smoot that no anti-dumping bill would be passed which did not specifically cover the reimportation of American made motor vehicles and equipment. The chief difficulty foreseen in connection with the bill as it now stands is the interpretation of what constitutes foreign merchandise. Whether American made goods sold abroad and then reimported into the United States by foreign purchasers could be placed in this category remains to be seen.

C. A. Vane, general counsel of the National Automobile Dealers Association, has asked for a hearing on the subject and will endeavor to have the bill so amended that there will be no loophole through which this automotive equipment can be slipped into the country and injure home industry.

American airplane manufacturers will seek the same protection, and the Manufacturers Aircraft Association also has asked for a hearing.

Must Equal Market Values

As the bill stands, a special dumping duty is provided in cases in which the Secretary determines that there is likely to be dumping. The duty imposed will be determined as follows:

"If the merchandise is sold by the foreign seller to an American purchaser having no interest in the business of the foreign seller, and the American purchaser purchases the merchandise at less than the foreign market value, the special dumping duty will be the difference between the foreign market value and the purchase price."

In case the merchandise is sold by a foreign seller having an interest in the American purchasing agency or by a

(*Continued on page* 990)

Industry's Production $3,594,814,620 in 1920

Exports Double Figures for Previous Year—Registrations Increase 22 Per Cent

NEW YORK, May 3—All records for the automotive industry were shattered in 1920. The remarkable showing made last year, notwithstanding the serious depression which came in the later months, is shown by statistics contained in the 1921 edition of "Facts and Figures," issued by the National Automobile Chamber of Commerce.

The total wholesale business in motor vehicles, parts, tires and accessories in 1920 amounted to $3,594,814,620. This included car and truck sales of $2,232,927,678, parts and accessories of more than $725,000,000 and tire replacement business of $636,750,000.

Many pages of the pamphlet are devoted to research supporting the statement of President Harding that "the motor car has become an indispensable instrument in our political, social and industrial life." It is shown that 3,000,000 motor vehicles are used by farmers, 100,000 by doctors, 30,000 by state governments, 10,000 by municipalities, 12,000 by rural schools, 4000 by packing companies.

Exports formed a larger part in the automobile business than ever, with 1920 having 7½ per cent of the total output, as compared with 4 per cent the year before. The total number of motor vehicles exported was 170,765, or more than double the 1919 figure of 82,652. The United Kingdom, British India, Canada and Cuba were the largest buyers.

The automobile to-day pays more special taxes than any other industry. Total levies upon the automobile in 1920 exceeded $316,720,000. More than $148,000,000 of this was in Federal taxes.

Enclosed bodies formed 17 per cent of the passenger car production as compared with 10 per cent in 1919.

Automobile registration in the United States in 1920 totaled 9,211,295, or 22 per cent more than 1919, according to the N. A. C. C. figures. Approximately 990,000 of these vehicles were motor trucks. South Dakota now has one automobile for every five persons. Iowa one for every five and a half, and Nebraska one for every 5.9.

Remarkable gains were made in the fuel supply during the year. Although threatened with a shortage in the spring, production was increased to a point where it reached 4,882,546,699 gal. of gasoline for the year, an excess of 626,118,674 gal. over the demand.

ITALY LIFTS TARIFF BAN

WASHINGTON, May 2—The Department of Commerce has been advised by the commercial attache at Rome that the Italian prohibition on the importation of American made passenger automobiles was removed April 19.

Outstanding Automobile Facts of 1920

Volume of Motor Vehicles, parts, tires and accessories, wholesale business	$3,594,814,620
Value complete car and truck output	$2,232,927,678
Value parts and accessories output	$725,136,942
Value tire replacement output	$636,750,000

Standard to Produce Steam Car and Truck

Company Is Organized in St. Louis to Build Vehicles Designed by Scott

ST. LOUIS, May 3—A manufacturing corporation to produce in St. Louis the steam vehicle designed during the past three years under the auspices of the Standard Engineering Co. has been formed under the name the Standard Steam Corp. A steam motor truck is added to the passenger car which was the first product designed by the company. All the assets of the company are taken over by the newly formed organization.

A number of prominent St. Louisans are interested in the corporation. The officers are: W. J. Parrish, formerly the Packard distributor in this city, president; Charles A. Lemp and L. L. Scott, vice-presidents; A. J. Lindsay, secretary and treasurer. The other directors are: Charles L. Holman, R. L. Hedges and J. L. Johnston. Among the stockholders are Russell E. Gardner, Jr., Benjamin Gratz, Anderson Gratz, John L. Moran, G. H. Walker, W. B. Dean, John H. Holliday, W. H. Bixby, W. K. Bixby, Fred W. Gardner, L. M. Rumsey, E. C. Stuart, Edward Beecher, Samuel Fordyce, John R. Carroll, H. D. Condie, Lewis B. Ely, Kurt V. Moll, Frank Wyman, W. H. Whitton and George B. Evans.

The chief interest centers in the steam motor truck which the corporation plans to produce, in view of the fact that it will be the first concern to manufacture this type of vehicle. L. L. Scott is designer of both the passenger car and the truck and has embodied many new principles in the new engine.

The Fifth Avenue Coach Co., which operates 300 motor buses in New York City, sent its general manager, G. A. Green, and two engineers to inspect and test the steam truck with a view of inaugurating the use of the steamers in their bus system. The final result of their investigations in this respect have not as yet been made known here.

Moline Plow Shows $1,935,289 Deficit

MOLINE, ILL., April 30—The effect of the readjustment in the implement industry last year, heightened by a reorganization, is reflected in the annual report of the Moline Plow Co. For the year ended Dec. 31, 1920, the company showed an operating deficit, after charges, of $1,320,289, and a total deficit, after preferred stock dividends, of $1,935,289. For the fourteen months ended Dec. 31, 1919, the operating income was $48,115, but after preferred dividends there was a deficit of $720,635. The current report shows the surplus reduced to $61,587, as compared with $1,996,876 at the end of 1919, while the surplus Oct. 31, 1918, was $2,717,511.

FEBRUARY SALES TOTAL 77 PER CENT OF 1920

NEW YORK, May 2—Additional evidence that the purchasing power of the United States has not been curtailed to such an extent as has been supposed, is found in the fact that total purchases of merchandise in February last averaged 77 per cent of the purchases for February, 1920, which probably was the largest February the merchants of the country ever had.

Statistics compiled by Roger Babson show that in the States of Arizona, Maine and Oklahoma the purchases in February, 1921, equaled or exceeded those in the same month the preceding year. States in which the percentage was 90 or over were Arkansas, California, Maryland, New Jersey, New Mexico, Pennsylvania and Texas.

States in which the percentage was more than 80 but less than 90 were: Connecticut, Delaware, Florida, Illinois, Indiana, Iowa, Louisiana, Mississippi, Nevada, New York, North Carolina, Ohio, Oregon, Utah, Virginia and Wisconsin.

States which had the lowest percentage were Colorado 63, Georgia 63, Idaho 64, Kansas 68, Tennessee 63, South Carolina 58, and Washington 65.

DUPONT INSPECTS UNITS

DETROIT, May 5—President Dupont, Vice-Presidents Sloan and Haskell and other heads of divisions of the General Motors Corp., are in Detroit this week inspecting the more important units of the corporation in this territory. The trip was made simultaneously with a regular meeting of the operations committee. Various questions of policy have been discussed but no announcement regarding them has been made.

CLARK MAKES NEW PISTON

LOS ANGELES, May 3—The Clark-Turner Piston Co. of this city has placed on the market an oversize piston which is cast on a special oversize core, so that the wall thickness is no greater than in the regular piston and the weight is only a fraction of an ounce greater. It is explained that most oversize pistons are cast exactly the same as the stock pistons, so the wall thickness is increased by one-half the oversize.

MIDLAND FORECLOSURE SOUGHT

OKLAHOMA CITY, May 2—A petition seeking foreclosure on property owned by the Midland Motor Co. of Oklahoma City has been filed in District Court by the Union Trust Co. of this city, alleging failure to pay interest on $52,000 worth of bonds. Date for hearing the suit has not been set. The Midland plant has been leased to the Wichita Truck Mfg. Co.

METAL MARKETS

IN both the ferrous and non-ferrous metal markets there is evidence of a very modest broadening in the consuming demand. The tonnages involved in the orders actually placed, are, however, light. Invariably after the metal markets have been in the doldrums for a period of several months, the first orders that break the deadlock between sellers and buyers are grossly exaggerated. This time-honored, though none the less misleading practice is due to the inherent shortcomings of market reporting. A sheet producer has an inquiry for 5,000 tons of sheets from an automotive consumer. He tells the truth about it. So does his competitor who has the same inquiry. Still another sheet mill is asked to quote on the same tonnage by the same consumer. By the time the inquiry gets into the market reports, it is presented as 15,000 tons of sheets being asked for, when, in fact, the tonnage, on which figures were requested, was only 5,000 tons. It frequently happens that a consumer, when in need of 25 tons of aluminum, sends a form letter to a dozen brokers operating in the "outside" market. By the time all of the brokers have told this or that market reporter of this inquiry, the demand for aluminum appears imposing when, in truth, only 25 tons are wanted. Especially under prevailing conditions producers are not finding any fault with this optical delusion. It may help to quicken the momentum of demand. Steel producers figure, and probably correctly so, that news of the buying of impressive tonnages by one passenger car builder will beget orders from others. As stated at the outset, the consuming demand is expanding but expanding slowly and, on the whole, tonnages involved are still subnormal. There is more inquiry for sheets than for other steel products. All of this is admitted and even emphasized but reports conveying the impression as though sheet mills were once more unable to fill the many orders for immediate delivery which they are credited with having received in the last few weeks are utterly deceptive and fraught with harm. There has been no over-night change in conditions, in fact, some of the inquiries emanating from the automotive industries which are for deliveries spread over the second and third quarters are strictly tentative and were intended as an encouragement to the steel industry to hasten wage readjustment.

Pig Iron—A more steady tone prevails with buying by automotive foundries on a hand to mouth scale. Everything depends on downward revision of freight rates. The Studebaker Corporation, Detroit, is inquiring for about 500 tons of foundry iron for July delivery.

Steel—On the new price basis of 3.10c., Pittsburgh, automotive consumers are taking up what cold-finished steel bars they still have due on old contracts but fresh buying is seemingly in abeyance. Rumors are afloat that some business in sundry steel products is getting onto books of the smaller "independents" at below the "stabilized" price levels.

Aluminum—The general feeling in the aluminum trade is that quickening of the demand from the automotive industry is not very distant.

Copper—Large consumers are picking up odd lots when they can get them at bargain prices. In one quarter, curtailment of production, as the result of shut-down of mines is placed at only 50 per cent as against 75 per cent heretofore accepted.

FINANCIAL NOTES

Studebaker Corp. has reduced its bank loans to $4,000,000. Production for the first quarter of the year as predetermined in January was at 50 per cent capacity. The company expects to make and sell 21,000 cars in the second quarter, which will break all records. Profits for the first quarter were $2,110,577. The latest balance sheet shows inventories sharply reduced.

Rogers Auto Sweeper Co. has been incorporated with a capital of $50,000 to manufacture automobile street sweepers. Howard C. Rogers was elected president and W. H. Duffy, secretary and treasurer. Duffy is director of public service of Columbus, while N. A. McCoy, one of the directors, is head of the Columbus street cleaning department.

Motor Products Corp. reports total assets to Dec. 31 as $8,185,724, in which is included inventories totaling $1,698,155 and cash of $411,340. The surplus totals $4,335,939.

Hess Mercury Carburetor Co., Valparaiso, Ind., has been made defendant in a bankruptcy action instituted by employees.

Bull Dog Tractor Co. has reorganized as the Bull Dog Tractor Corp. and the capital reduced from $750,000 to $250,000.

Perfection Tire & Rubber Co. will proceed with its recapitalization plans following ratification by stockholders.

Nash Motors Co. paid the regular quarterly preferred dividend of 1¾ per cent on May 2.

INDUSTRIAL NOTES

Manley Mfg. Co. has taken over the inventory, dies, jigs, fixtures and patents of the J. B. S. Mfg. Co., Elmira, N. Y., manufacturers of the Ellis-Smith line of automotive equipment. The Manley company plans to continue the manufacture of the line practically in its entirety in this city.

H. P. Rhodes, formerly with the Howe Lamp & Mfg. Co. and the New Era Spring & Specialty Co., and T. F. McMurray, former manufacturer of Indianapolis, have formed a company at Fort Wayne, Ind., to act as manufacturers' sales agents.

Motor Wheel Corp., Lansing, Mich., has established a branch office at Detroit in charge of H. H. Crawford, who will represent the Gier Tuarc Steel Passenger Car Wheel in Michigan and Ohio.

Motch & Merryweather Machinery Co. of Cleveland has taken over the sales of the Gordon cam turning lathe, which is now being manufactured by the Willard Machine Tool Co. of Cincinnati.

W. D. Blood & Co., Inc., exporters and importers, New York, have opened a branch office in Boston for the exclusive purpose of looking after the trade in the New England States.

Sterling Tire Corp., Rutherford, N. J., has opened a western branch in Chicago. It has announced a policy of keeping its branch houses to as low a number as possible.

Hines Combine Harvester Co., Hutchinson, Kan., has adopted the Climax model "T" 5½ x 7-in. engine as standard power equipment for its combined harvesters.

Alvord Reamer & Tool Co. has opened a branch office in Chicago, where it will carry a complete stock of products. O. B. Cole is manager.

Automotive Gear Works, Atlanta, will establish a branch in Seattle to serve Pacific Coast points. H. M. Clark will be manager.

Gill Mfg. Co. has established branches at Spokane, Wash., and Houston, Texas., bringing the total of company branches to 41.

Lafayette Tractor & Machinery Co., Lafayette, Ind., will add three units to its plant to increase distribution and production.

Franklin Automobile Co. reports orders on April 28 for 885 cars for May delivery. Production for the month will aggregate 920 cars.

Pennsylvania Piston Ring Co., Inc., Cleveland, beginning with May 9, will run a full night shift in the production of piston rings.

Stewart-Warner Speedometer Corp. reports April sales as equalling those of the first three months of the year combined.

George H. Gibson Co., consulting engineers, has removed to the Hide & Leather Building, New York.

United Automotive Body Co., Cleveland, has acquired new plants at Streator, Ill., and Evansville, Ind.

Oakes Co., Indianapolis, has acquired the Toelle patent covering lock housings for screws and bolts.

Iron City Products Co., Pittsburgh, has changed its name to the Rees Mfg. Co.

Keystone Rubber Co. reports a $500,000 loss by fire at the Erie, Pa., plant.

Spafford Co., Inc., Boston, has removed its offices to 10 Arlington Street.

Continental Piston Ring Co., Memphis, has moved into its new building.

Ford Reaches Schedule of 4000 Cars Daily

DETROIT, May 3—Announcement is made by the Ford Motor Co. that production at its Highland Park plant has reached a schedule of 4000 cars a day, equaling the number produced at the peak last year. The force of workers is being increased daily and nearly 40,000 men are now reported employed. At the beginning of April the company had orders on hand for more than 200,000 cars.

GENERAL TRACTORS BANKRUPT

MADISON, WIS., May 4—General Tractors, Inc., a Delaware corporation with plants at Watertown, Wis.; Bramford, Ont., and Paulsboro, N. J., manufacturing the Monarch creeper type tractors, has been adjudicated a bankrupt. The referee is C. F. Lamb of this city. The last balance sheet of the company showed assets slightly in excess of $2,000,000.

ARMY SALE NETS $150,000

JEFFERSONVILLE, IND., May 2—Twenty-seven hundred trailers, two-wheeled, one-ton capacity, sold for an average of $55 in lots of five in an auction at the quartermaster's depot here. Motorcycles and side cars in lots of ten sold for $100.00, none in good condition. Passenger cars sold for $60 to $80. A total of 3500 motor transport units were sold for a total of $150,000.

BANK CREDITS

Written exclusively for AUTOMOTIVE INDUSTRIES *by the Guaranty Trust Co., second largest bank in America.*

NEW YORK, May 5—Call money was again unchanged last week with a range off 6 per cent to 7 per cent and with a ruling rate not above 6½ per cent until Friday, when 7 per cent was quoted all day. The firmness of the week-end carried over until Monday of this week. Preparations for the month-end settlements and the report of the New York Associated Banks, showing reserves $3,455,360 short of legal requirements, were factors partly responsible for the firmer rates toward the close of the week. There was little business done in the time money market. Nominal quotations for 90 days' to five months' paper were 6 per cent to 6½ per cent, while six months' paper commanded 6 per cent to 7 per cent. The previous week, 6½ per cent to 7 per cent was quoted for all maturities. Commercial paper rates receded in the latter part of the week to 7 per cent to 7½ per cent for 60 to 90 day indorsed bills and six months' paper with choice names.

In accordance with its new policy, the Federal Reserve Board published its weekly statement as at the close of business on Wednesday of last week instead of Friday, as heretofore. The System gained $19,498,000 in gold reserves last week, while cash reserves increased $11,959,000. Total bills on hand decreased $50,960,000, and total earning assets $55,580,000. Total deposits also declined $23,452,000, and Federal Reserve notes in circulation $26,580,000. As a result of these changes, the ratio of total reserves to deposit and Federal Reserve note liabilities combined increased from 54.1 per cent to 55. The ratio of gold reserves to Federal Reserve notes in circulation, after setting aside 35 per cent against deposit liabilities, increased from 65.8 per cent to 67.2 per cent. A corresponding gain was made by the New York Federal Reserve Bank.

The week was marked by several features of an unfavorable character. The Pennsylvania Railroad reduced its dividend from 6 per cent to 4 per cent—the lowest dividend paid by this road since 1891, while at least 6 per cent had been paid since 1900. The report of the Steel Corporation for the month of March revealed earnings smaller than for any month since April, 1915. Operations during the first few months were said to be at the rate of 90 per cent in January, 75 per cent in February, and 51 in March.

There were, nevertheless, signs of reviving confidence in many quarters. The stock market showed evidences of renewed interest by the public, with larger trading and rising prices, while the bond market absorbed a $230,000,000 joint issue of the Great Northern and Northern Pacific Railroads, and at the same time the general list showed a stronger undertone with slightly advanced prices. The foreign exchange market showed a decided upward trend, Sterling reaching a new high point.

MEN OF THE INDUSTRY

Norton H. Van Sicklen has been elected president and general manager of the Reliance Wheel Co., manufacturer of a steel double disk wheel. The company is preparing to increase production and has under option a manufacturing plant equipped with the necessary machinery. Van Sicklen formerly headed the Van Sicklen Speedometer Mfg. Co., which was recently sold to the Stewart-Warner Corp. He is known to the iron and steel trade as a former official of the American Steel & Wire Co. J. M. Crenan is director of sales of the Reliance company and Charles T. Gaither, prominent member of the Youngstown Automobile Dealers Association, and president of the Youngstown Auto & Repair Co., is elected vice-president of the Reliance Wheel Co.

H. R. Hyman, advertising manager of the Cole Motor Car Co., of Indianapolis, will be one of the speakers at the annual convention in June of the Associated Advertising Clubs of the World. He will talk before the screen advertising department on "Merchandising Through Motion Pictures." The Cole company was one of the pioneers in the automotive field to use motion pictures for advertising purposes, through the production of "The Porcelain Lamp," a film that deals with the transportation problem from the first time wheels were invented down to the modern motor car.

L. F. Hosley, has been appointed production engineer of the Kelly-Springfield Motor Truck Co., Springfield, Ohio, and will be in charge of all production and assume responsibility for the quality of the product. Hosley was formerly assistant engineer of the Mercer Automobile Co. and prior to that was in the engineering department of the Locomobile Company.

Russell B. Reid, for several years with the Edward R. Ladew Co. as assistant sales manager, has been made manager of sales for the Sharon Pressed Steel Co., Sharon, Pa., manufacturer of motor car frames, industrial trucks and pressed steel automobile parts. Reid will direct the sales of the company from the New York office at 66 Broadway.

George E. Meurs has been appointed manager of the New York export branch of the Miller Rubber Co. He will be directly responsible to the Akron export department, which is in charge of C. E. Wagner. Meurs has had a varied export experience covering a period of thirteen years in Latin-America and New York City. He is succeeding Victor Roth.

J. J. Lowcher has resigned as credit manager of the Eisemann Magneto Corp. He has made no definite plans for the future. Lowcher went with the Eisemann company two years ago after his discharge from the army. He served seven years with the American Smelting & Refining Co. as travelling auditor and acting agent.

Alfred Reeves, general manager of the National Automobile Chamber of Commerce, completed his spring trip among the dealers with an address at Rochester. In his itinerary from Omaha to Boston he addressed 9000 dealers and bankers in the larger trade centers. Reeves will now turn his attention to tariff and taxation matters.

Stephen A. Howell, formerly in charge of the Chicago branch of A. Schrader's Son, Inc., has been promoted to the post of manager of the Schrader Toronto branch, succeeding Harold R. Cole, who is now at the main office of the company at Brooklyn. Howell joined the Schrader company at Brooklyn in 1915.

Clifford Holder of Illinois has been appointed chief engineer for the North Carolina Highway Commission. Nine district engineers have been elected as follows: J. C. Gardner, R. E. Snowden, Will Morson, F. E. Schanpfe, John D. Waldrop, J. D. Pridgen, C. E. Currie, H. E. Noell and Wythe M. Peyton.

J. A. Benell, formerly assistant general manager for the Haynes Automobile Co., has been appointed district sales manager for California, Oregon, Idaho, Nevada, Washington and Arizona.

Howard K. Ford has resigned as manager of the Hastings Mfg. Co., Hastings, Mich., and has accepted a position as manager of the Winter Stamping Co., Goshen, Ind.

Harold E. Taylor, who was previously with the Gemco Mfg. Co., is now acting as sales manager for the Las-Stik Patch Mfg. Co., Hamilton, Ohio.

Blake Named President of Paragon Motors

CUMBERLAND, MD., May 2—Philip M. Blake of this city has been elected president and general manager as well as a director of the Paragon Motor Co., which has removed its plant here from Connellsville, Pa. The engineering department, which has been located at Cleveland, will be moved here at once and will be under the direction of P. F. Hackethal, the chief engineer. During the past year the engineering department has designed, built and tested four model Paragon cars. The Paragon engine is of four-cylinder design and has 12 valves operated by a single camshaft. Aluminum is used extensively in its manufacture.

Charles E. Barley, the sales manager, says that orders now on hand will consume a considerable portion of the first years production. The Paragon car will be produced in several body models built upon a standard chassis with a list price ranging between $3000 and $3500.

M.A.M.A. to Develop Membership Groups

NEW YORK, May 4—A new group plan of inter-organization is about to be established by the Motor and Accessory Manufacturers' Association. The plan will divide the membership of the association into a number of groups, each of which will comprise manufacturers of a certain product and each of which will have officers and meetings of its own.

The plan is designed to offer members of the association "an apportunity to meet with others in the same lines of manufacture, at periods as often as they themselves may determine, provided that not more than six consecutive months elapse between such meetings."

A detailed plan for the establishment and conduct of the new inter-organization has been approved by the Board of Directors and General Manager Heminway of the association and has been submitted to members for approval. Many replies have been received from different parts of the country, all of which indorse the plan heartily. General Manager Heminway states that the plan is certain to go into effect and that it will undoubtedly make for greater unity.

Highway Traffic Body to Hold Open Sessions

NEW YORK, May 4—The annual meeting of the National Highway Traffic Association will be held at the Automobile Club of America, this city, on May 13. A dinner will be served at a nominal cover charge for which reservations should be sent to Secretary Elmer Thompson at the Automobile Club. The public has been invited to attend the dinner and also to take part in the discussions scheduled.

Addresses will be delivered by J. E. Pennybacker, secretary of the Asphalt Association, on "Relation of Methods of Financing Highway Improvements to Present and Future Traffic," and by Prof. Arthur H. Blanchard of the University of Michigan, on "Highway Improvements Should be Based on Transportation Surveys."

Annual reports of the officers and standing committees will be received and acted upon and officers will be elected for the year 1921 and 1922.

April Car Shipments 27 Per Cent Over March

NEW YORK, May 4—Figures compiled by the National Automobile Chamber of Commerce show that shipments of automobiles in April, exclusive of Fords, increased 27 per cent over March. Last year April decreased 23 per cent under March. Shipments from 50 factories indicate that the April total will be 20,000 carloads, 13,800 driveaways and 1134 shipped by boat. This is 71 per cent of the shipments in April, 1920.

While the railroads carried more automobile shipments in April of this year than last year, because of the lack of car supply and strikes, the difference in production is accounted for in driveaways.

WESTCOTT SHOWS MAY GAINS

SPRINGFIELD, OHIO, May 2—Shipments of automobiles from the plant of the Westcott Motor Car Co. during the month of April doubled that of any previous month since last fall, according to official announcement. "There has been a pleasing revival of business in almost every section of the country," said E. H. Gilcrist, sales manager. "While our business has shown a constant improvement since the first of the year we were hardly anticipating such an increase in April. Our advance orders now on hand for May delivery indicate a larger number of shipments for the next month, although the proportionate gain will not be so large."

Calendar

SHOWS

Sept. 28 - Oct. 8 — New York, Electrical Exposition, 71st Regt. Armory, Electric Equipment, Machinery and Vehicles.

Nov. 27-Dec. 3—New York, Automobile Salon, Hotel Commodore.

January — Chicago, Automobile Salon, Hotel Drake.

FOREIGN SHOWS

May 28, 1921 — Czecho-Slovak International Automobile Exposition of Cars, Trucks, Tractors, Motorcycles and Equipment. Prague.

May 28-June 8 — International Automobile Exhibition, Basle, Switzerland.

June, 1921—Reykjavik, Iceland, Agricultural Exhibition—Agricultural Machinery—Icelander Agricultural Society, Reykjavik, Iceland.

September—Buenos Aires, Argentina, Passenger Cars and Equipment. La Pabellon de las Rosas. Automovil Club Argentino.

September—Buenos Aires, Argentina, Cars, Trucks, Tractors, Farm Lighting Plants and Power Farming Machinery. Palermo Park; Sociedad Rural Argentina.

September—Luxemburg, Luxemburg, Agricultural Sample Exhibition.

Oct. 5-16—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

Nov. 4-12 — London, British Motor Show, Society Motor Mfrs. and Traders.

CONVENTIONS

May 17-19—Buffalo, Convention of Factory Service Managers, Auspices of Service Committee, N.A.C.C.

May 23-26 — Chicago, A.S.M.E. Spring Meeting, Congress Hotel.

May 24-28—West Baden, Ind., Summer Meeting Society of Automotive Engineers, West Baden Springs Hotel.

June 20-25 — Mackinac Island, Mich., Summer Meeting Automobile Equipment Association.

Oct. 12-14, 1921 — Chicago, Twenty-eighth Annual Convention National Implement & Vehicle A'ssn.

RACES

May 31 — Indianapolis, International Sweepstakes.

June 3-5 — Reno, Nev., First Annual Nevada Highway Road Race.

June 18—Uniontown, Pa., Speedway Events.

July 25—Grand Prix, Le Mans.

Labor Day—Uniontown, Pa., Autumn Classic.

S. A. E. MEETINGS

Metropolitan Section — May 3, Car Theft.

Midwest Section — May 13, Smoker, Dinner and Entertainment at Chicago Automobile Club.

Dayton Section—May 17, H. L. Horning.

Cleveland Section—May 20.

Anti-Dumping Change Makes Mellon Judge

(*Continued from page* 985)

foreign seller in which the American purchasing agency has an interest, at a price below foreign market value, the special dumping duty will be the difference between the foreign market value and the exporter's sales price.

If there is no foreign market value the special dumping duty will be the difference between the cost of production and the purchase price. It is believed that it will seldom be necessary to use this method except in cases in which the article is only sold for exportation to this country.

There has been much debate as to what constitutes the export value of these American trucks, sold abroad and reshipped by foreigners to American markets. The Senate has defined the term "export value" to be the price at the time of exportation to this country at which the article or similar article is sold or freely offered for sale for exportation to the United States to all purchasers in the principal markets of the country from which exported.

Truckmen "Hope for Action"

DETROIT, May 4—The motor truck committee of the National Automobile Chamber of Commerce spent some time here to-day discussing the anti-dumping bill now before Congress, and hope was expressed that action would be taken to protect the industry against the reimportation evil.

Most of the time at the meeting was devoted to a general discussion of conditions. A report on legislation was read and it was said that with only six state legislatures still in session only ten states have failed to adopt legislation providing that 800 lb. per inch of tire shall constitute a standard motor truck load.

Plans were formulated for promoting store door delivery by motor truck, and representations on this subject will be made to the Interstate Commerce Commission. It is hoped to obtain the cooperation of railroads in having short haul business turned over to motor trucks.

The highway committee of the N. A. C. C. at a meeting yesterday discussed the redraft of the Townsend highway measure now pending before Congress. Roy D. Chapin and George M. Graham were delegated to go to Washington to appear before the committee, probably next week. The committee approved the principles of the Townsend bill as it has been redrafted.

Maxwell Stockholder to File Amended Suit

WILMINGTON, DEL., May 3—Permission to file an amended bill of complaint against the Maxwell Motor Co., a Delaware corporation with its principal factory in Detroit, designed primarily to stop the sale of the assets to a new corporation which was formed to take over the Maxwell and Chalmers companies, has been granted Holmes Jones of this city, a Maxwell stockholder, by Chancellor Curtis. Jones alleges that through "reckless waste and dissipation" the Maxwell Motor Co. lost $25,933,194 in sixteen months.

Jones filed a bill of complaint with the court of chancery on Dec. 11 last, asking for the appointment of a receiver for the Maxwell company on the ground of insolvency. Application was made for demurrer, and while this was pending Jones asked permission to amend his complaint. Meanwhile the United States courts at Detroit, Indianapolis and Columbus granted friendly applications for a receivership under which President W. Ledyard Mitchell will take over the affairs of the Maxwell company.

BUS LINES SUPPLANT TRAINS

ALBANY, GA., May 2—Automobile buses are fast supplanting passenger trains as carriers in the southern half of Georiga. The buses are meeting with unusual success.

Corsican Grand Prix Won by Bignan-Sport

PARIS, April 23 (*By Mail*)—Albert Guyot, driving a special 183 cu. in. Bignan-Sport, won the Corsican Grand Prix yesterday, covering the distance of 274½ miles in 6 hours 7 min. 51 2/5 sec., or at an average of 45 m.p.h. This race was the first ever held on the island of Corsica, and was limited to cars having a piston displacement of not more than 183 cu. in. with four-passenger bodies of given dimensions, with fenders, windscreen and touring equipment. A cash prize of $20,000 was awarded the winner.

Only nine cars were entered, these being 2 Bignan-Sport, 4 Turcat Méry, and 3 Chanard-Walcker. Three laps of a most difficult and varied course had to be covered, the road varying from a 30 mile dead level stretch by the side of the sea to a wild climb over the mountains where the rough surface made fast going impossible.

Guyot took the lead on the first lap and held it throughout the race. During the initial lap he was closely followed by his team-mate, Nougué, but this car dropped out on the second lap, and the running was taken up by Dauvergne on a Chenard-Walcker, and then by Rougier on a Turcat-Méry, who finished second, 35 minutes behind the winner.

FORM AIR PILOT ASSOCIATION

TORONTO, April 29—During the winter months there has quietly come into existence an organization, named the Commercial Air Pilots' Association of Canada, which has for its aim the elevation of aviation standards in general, and the best interests of the flying man and his employer in particular. The intention of the association is to link together the commercial pilots of the country as a united body, who, in working for the advancement of aviation, will benefit themselves at the same time. The association will keep on file all the latest and up-to-date information on aircraft and other details.

AUTOMOTIVE INDUSTRIES
THE AUTOMOBILE

VOL. XLIV. NEW YORK—THURSDAY, MAY 12, 1921 NO. 19

Long Credits Greatest Need, Voice of Export Meeting

World's buying needs only temporarily halted and sales will quickly be revived if we can grant terms, is the sentiment of Eighth Annual Foreign Convention. Domestic finances ample to aid situation

By David Beecroft

NO words spoken to the 2000 delegates of the Eighth National Foreign Trade Convention, during the four-day session at Cleveland last week, struck a stronger sentiment or was received with more zest than those of W. P. G. Harding, Governor of the Federal Reserve Board, who, in speaking on the financial and industrial situation of to-day, declared:

> **"We are on a very much safer basis today than a year ago. The Federal Reserve Banks are to-day in a strong position, with an average reserve percentage of gold and lawful money against deposits and note issues of 55 per cent as compared with 42 per cent a year ago. The reserves of the Federal Reserve Banks are now on a higher basis than they have been since the fall of 1918 before floating the fourth Liberty Loan."**

Governor Harding followed this declaration with the suggestion to industry that liquidation has proceeded as far as necessary and that many industries having liquidated to the bone, the Federal Reserve Banks are now able to take part in the movement to stimulate business with a view of liquidating credits that have not been ready previously for this operation. He added:

"The present is a time for courage. In the present situation, when many institutions find credits formerly liquid now in a frozen state, it is important that something be done to start a movement to stabilize business by liquidating these frozen credits. The banks that are carrying these frozen credits have assets back of them to protect them, but they are in turn called upon to furnish new credits for productive processes. Any loan made to-day on a basis of current values is necessarily a sounder and safer one than loans made a year ago on the basis of values then obtainable. Frozen credits can best be thawed by a movement to do business, and in that new movement should not be overlooked the necessity of building up our foreign trade.

"With liquidation as it has taken place in the past year behind us, those industries that have liquidated should be encouraged to build themselves up, and herein is the reason to-day for renewed courage and confidence. We will reach and are reaching every day a safer basis on which to do business. Production cost will be reduced; certain prices will be badly depressed, some to below costs of production and even below the 10-year average, and then will advance to the common level, and the prices of other products will come down to meet them."

Business Dishonesty

Not less important as signifying the attitude of the delegates was the warmth with which the statement of Fred I. Kent, Bankers' Trust Co., to the effect

that the result of the devastation to industry wrought through business dishonesty has probably been more detrimental to the world at large than the devastation caused directly by the war. Kent was not the only speaker of the convention to refer to the deplorable lack of business integrity that has exhibited itself since the armistice. It was a very recurrent convention topic, coming to the surface in the general sessions of the convention as well as in the group sessions. The total loss of respect for contracts had ramifications not appreciated by many. Kent looks for business improvement just as soon as moral improvement occurs, and the speed of business improvement will largely depend on the speed of moral improvement and the speed at which pre-war respect for contracts returns.

Speaking specifically on this subject, Kent contrasted the trade relationships between the American producer and the foreign buyer previous to the war with recent relationships, saying:

"Under ordinary conditions, with law and order enforced throughout the world and integrity and purpose as it once existed, general letters of credit as used previous to the war answered all the demands of foreign trade. Then the foreign trade of the world was carried on as successfully as domestic trade, and the danger involved in time and place between buyer and seller was practically eliminated.

"Under conditions as developed since the war, the importer of American products has not been properly protected. He could not force shipments by the manufacturer. During times of rising prices the exporter could break his contract and neglect to make shipments, notwithstanding that the importer had sales made against such purchases and, when the goods did not arrive, could not make deliveries and was obliged to break his contract under penalty.

Shipments As Prices Fall

"The difficulty of the importer was further aggravated when prices began to fall and foreign exporters, who had letters of credit in their possession which had not yet expired, took advantage of the situation and made shipments. In many cases importers, not expecting to receive goods because of previous default in shipments, had contracted for other goods. This form of dishonesty on the part of exporters was exercised in many cases where satisfactory relations had been carried on between the manufacturer and importer for four years.

"As a result of this situation, seaports are clogged with goods which cannot be disposed of without great loss and which have aggravated stagnation in trade. Unfortunately, foreign exporters and importers have not been the only delinquents, as many Americans have been just as bad. During the time of falling prices, repudiation in connection with domestic trade was as general as in foreign trade. While prices were rising, manufacturers and producers failed to make deliveries; when prices began to fall, purchasers refused to accept goods contracted for.

"That such a development should occur in the United States shows the depth to which the level of integrity had fallen, due to the world-wide propaganda that has been carried on by those who would destroy the institutions of civilization in order that they might become possessors of goods which they claim others have not the right to hold. This vicious propaganda has reached its height and the morals of the people its greatest depth. A turn has taken place in the minds of men that will continue with growing force until the re-establishment of business integrity has been effected.

"As the moral forces of men gather it will again become possible to carry on trade in a normal way except that it is going to take time to overcome the effect of the devastation in industry which has been wrought through dishonesty. That has probably been more detrimental to the world at large than the direct devastation caused by the war.

"During this period of reconstruction a longer period than usual is going to be required for payment of goods imported by the nationals of many countries of the world. If such additional time is not allowed, the return to normal trade is going to take longer than otherwise need be true, during which time the difficulties of all peoples will continue."

Longer Credits

Of prime importance for the stimulation of foreign trade, which has been falling off for several months, longer credits are necessary. **The fallacy of considering cash against documents at seaport as the ideal scheme for foreign trade has been exploded.** European nations are in the market, and the necessity of any country engaged in foreign trade, buying as well as selling, has taken hold. Foreign trade consists essentially of buying and selling. You cannot have it unless these two factors are present. It is not possible for any country to be unto itself any more than it is possible for any man to live unto himself, for any family to live unto itself, or for any community to live unto itself.

Profits are an essential of foreign trade, but need not be the motive. There can be no real development of any nation unto itself. Under such a condition retrogression will start.

As an example, witness certain interior provinces in China which for nearly 2000 years have lived unto themselves and to-day are not as far advanced as at the birth of the Christian era.

A still further necessity for foreign trade is that the natural resources of the world must be united before they can best serve the world. As this is accomplished through foreign trade, the general level of nations will rise slowly during the year. Foreign trade is essential to the intellectual development of the people.

How long credits will increase foreign trade was suggested by W. C. Redfield, president of the American Manufacturers' Export Association, who said that he knew of orders waiting for $20,000,000 worth of American goods to be sold in the foreign field just as soon as extended credit under the Edge act could be established. The machinery for extended credit is one of the prime requisites of foreign trade. It is impossible for the United States, with a file and saw as its tool equipment in foreign trade, to compete against European nations which have modern machinery for financing their foreign trade. Redfield declared that we have reached the end of our financial power in export trade and unless something is done by way of improving the machinery for financing this trade, we have reached the top of our foreign trade. A British exporter, continued Redfield, can go to five or six places and obtain credit for one to six years on export goods.

Senator Edge Speaks

Senator Walter E. Edge of New Jersey, father of the Edge law, establishing debenture banks by which long-term credits in foreign trade are possible, speaking at the annual dinner at the close of the convention, urged the establishment of confidence at home and the extension of credit to the foreign buyer as the best method of stimulating domestic production. He re-echoed the words of Governor Harding of the Federal Reserve Board when he stated that national prosperity is dependent on pro-

duction in industry and that the first medicine for the buyers' strike must be confidence, and for the foreign situation it must be the provision of credit and the transmutation of that credit into dollars to pay American producers and labor and agriculture. The foundation of all business is confidence and credit is the cornerstone. There can be no confidence among the people while uncertainty prevails as to the nature of the remedies to be provided for the present uncertainty and apprehension.

Senator Edge believes buying power exists both at home and abroad and that this can be stimulated at home by a return of a confidence that can be brought about only by a realization that men can develop, can make a reasonable profit on their enterprise and then retain that profit. The foreign market can be stimulated by an extension of credits, and the nations seeking to buy have the necessary security to protect such credits. With the Webb Act, legalizing combinations for export business, and the Edge Act, providing for extended credits, American industry has the necessary facilities for foreign trade.

Foreign Investments

American investors will have to be educated to the advantages of foreign securities much as the investing public of European countries were previous to the war, according to George R. Meyercord, president of the Illinois Manufacturers' Association, who declared that millions of dollars' worth of export business is at present being lost to America because of our attitude toward foreign investments. If this prospective trade was written into orders many of our idle factories could operate at capacity.

Under the Foreign Trade Financing Corporation the American investing public, which now loans vast sums on the security of a farm, a house or factory, will place its money abroad with more security than the mortgages just referred to. Back of the debentures will be the huge capital guaranty, and back of that again in each case will be the large variety of collateral which will, in the aggregate, create a law of averages that will be so certain to insure repayment to the corporation as to make the risk infinitesimally small to the investors.

Meyercord cited numerous examples of how foreign trade is being lost to-day because of inability to handle credits such as can be handled when the Foreign Trade Financing Corporation is operating. One example was that of a total order of $20,000,000, consisting of fifteen different varieties of merchandise, which order could not be accepted, due to existing banking conditions. Another example was that of a large pulp and paper company in Scandinavia desiring to purchase $500,000 of logging machinery. This company was willing to store enough of its manufactured product to guarantee ample security if the necessary credit could be established. The order was lost. Another example was that in which the proposed purchaser was a Scandinavian municipality. The city offered as security for credit city bonds and tax warrants, due six to nine months later. The amount of the tax warrants were many times in excess of the amount of the purchase. It was not possible to give the nine months' credit necessary and the purchase was made in other countries where such credit was obtained.

Frank H. Taylor, president of the S. S. White Dental Manufacturing Co., expressed the belief that it will be a reflection on us as manufacturers and bankers if we cannot get together and establish some machinery for international trading. Our customers in foreign lands need our goods and cannot pay for them to-morrow or the next day, and they have a right to ask for long credits because we have become a creditor nation and should be able to give them financial assistance. Foreign credits must not be granted by chance, and it is our responsibility that a stabilizing plan be set up to regulate such.

As to how lack of credit is affecting the export lumber situation, J. J. Donovan, vice-president of Bloedel-Donovan Lumber Mill, said that under present conditions the foreign buyer is required to furnish a letter of credit to accompany his order, which means that his credit has to be such as to enable him to pay for the cost of the cargo two, three or four months before shipment, which would mean four or five months before delivery is made to him in the foreign port. He must also pay freight in cash not later than the delivery of the cargo, which is another restriction to trade. America has the lumber to sell, the world desires to buy lumber, the buyer is solvent, but has neither cash nor goods immediately available for payment. His record for honesty is good. He has paid in the past, he will pay in the future. How can we tide over the present? The banker must come in to provide for continuance of necessary business by arranging credits which his reserve capital warrants. It is a question of credit for these foreign firms of established reputations. Without these credits business stops. A better understanding of the problem of credit will revive trade.

Legislation

As to how American foreign trade is being hampered in certain portions of the world by unfavorable legislation the present situation in China is an example. Our present Revenue Act of 1918 requires American citizens doing business in foreign countries to pay the same income taxes that are paid by resident citizens. This is working as a serious handicap on our foreign trade in that rival countries, such as Great Britain, do not require their nationals engaged in trade in other countries to pay such taxes. The British merchant resident in practically every port and market of the world has been encouraged by the government, and his freedom from home taxation has been an important factor in putting British overseas commerce into its commanding position. A more specific example of the hardship worked on American merchants resident in other parts of the world is that of the American citizen doing business in the Philippine Islands. He is required to pay his income tax to the United States, whereas the merchants of other countries resident in the islands are relieved from such. Very frequently this tax represents the difference between success and failure, and if such tax could be put into a reserve fund, as is done by the nationals of other countries, American commerce would benefit materially. The importance of this in the Philippines will be clear by an example:

On an income of $600,000 the United States income tax is $375,190. The Philippine income tax, which a national of another country would have to pay, is $77,735. This means a difference against the American merchant of $297,455. On an income of $100,000 there is a tax difference against the American merchant of $24,205. No American can establish a business in any foreign country to-day without facing a fact that the disadvantage worked on him by this income tax requirement may nullify his efforts and leave him at the mercy of his more fortunate rivals.

In connection with this handicap on the American merchant resident abroad it should be borne in mind that the Philippine Islands front directly on China, which is considered by many to be the greatest field in the whole world for commercial development. The Port of Manila has one-half of the population of the globe

within a radius of 3000 miles, and there are many of the big centers of the East, such as Singapore, Hongkong, Shanghai, Yokohama, etc., etc., within a radius of 1500 miles, or a five-day sail.

Daniel R. Williams of the American Chamber of Commerce, Manila, declared that unless the discrimination worked by the Revenue Act of 1918 against our merchants in the Philippines is promptly and effectively relieved, the inevitable consequence will be to paralyze and destroy what we have already accomplished in the islands and render abortive every project formulated or in prospect for the future.

The serious character of the Revenue Act of 1918 is that it falls on Americans doing business there, while Filipinos, British, Japanese, Germans and trade rivals of every other race and color are not so taxed. As these latter pay no tax to their home governments on their Philippine income, it results that in our own dependencies and under our own flag we penalize our countrymen in favor of foreigners. Further, Americans in the Philippines have no voice or participation in the enactment of our laws, and taxing them for the benefit of the home government is not without analogy to certain events connected with the early history of our country when Great Britain attempted to impose certain stamp acts on the colonies.

A sentiment favorable to having Congress pass what is known as the China Trade Act of 1921 was expressed by the convention. J. B. Powell, Shanghai, in mentioning the necessity for the passage of this act, showed how an American merchant desiring to do business in China must organize a company under the laws of one of our forty-eight states, which laws are not satisfactory for such a purpose.

A $500,000 Handicap

The case is similar to that of taxation in the Philippines. A case in point being that of a Boston concern, doing business in Shanghai, paid $500,000 in taxes to the United States in two years, whereas rival British concerns did not have to pay $1 to their respective governments during the same period. We have to-day a good American selling personnel in China, and the China Act is designed to place United States nationals on a basis of equality in the matter of trade with the nationals of other countries doing business in China. During the war we increased our trade with China from 6 to 17 per cent, but now that European countries are back in the field there is grave danger that our trade will fall back to 7 per cent unless Congress passes legislation such as the China Act.

At present 67 per cent of the total foreign commerce of the Philippine Islands is with the United States, but there is no reason why this should not be 95 per cent, according to the wishes of the natives, if due regard is made for trade requirements. The Filipinos have a feeling that American citizens resident in the United States should invest in Philippine bonds, such as those needed to improve the Port of Manila. There is objection on the part of the Filipinos to certain trade restrictions on products of the Philippine Islands, particularly as the Philippine legislature has no voice in tariff relationships between the islands and the United States. This function rests entirely with Congress, which is considered highly unfair by the Filipinos. There is a strong demand for the restoration of normal exchange with the islands, as well as a demand for long credits until conditions become normal. The putting in commission of several ships between our Pacific Coast and the islands during the past year had a favorable influence on trade, but unfortunately at the present time the cable between the islands and the United States is not working and messages are sent by way of Europe.

Merchant Marine

A serious situation in connection with our foreign trade was voiced by James A. Farrell, chairman of the National Foreign Trade Council and president of the United States Steel Corporation, as the future of our merchant marine. He said that serious consideration must be given the problem of maintaining it under present handicaps. The steel ships constructed by the Shipping Board are as good as those built by any of our allies, he said, but constructive legislation must be enacted if we are to benefit by these ships as we should. Farrell declared a serious error was made in 1919 by the Shipping Board not disposing of a large portion of the fleet at prices bearing a fair relation to moderately depreciated cost.

An opportunity to realize at least $800,000,000 was lost, this sum representing the difference between the value the ships that might have been sold at that time and their value to-day. It is questionable whether under present conditions any part of the merchant fleet could be sold to-day except at a sacrifice.

He recommended laying the ships up rather than making such a sacrifice, and declared that the United States should never again be placed in the position of being without sufficient ships to support its army and navy. There is too much ocean tonnage at present, and Farrell recommended an international laying-up of ships program on the basis of relative percentage of tonnages owned by the different nationals.

As a direct bearing on our foreign trade, Farrell urged American exporters to ship by American ships, even if the cost is higher than on ships of other nations. He urged American exporters of bulk commodities to sell their goods on a cost-insurance-freight basis, thereby controlling the ocean freight and allowing American ships a reasonable rate. He did not urge this as an appeal to patriotism but an appeal to reason, since our producers cannot know their markets, nor the laid-down paraty of their competitor's prices unless they include in their sales price the cost of their goods, the insurance and ocean freight to the ultimate destination. It is up to American producers to support our shipping in this crisis. It will be necessary to repeal the navigation laws which are not only strangling our ocean-going shipping but affecting our carriers on the Great Lakes. One of these laws requires the engine room crew on an American freighter to be 30 per cent larger than on the steamships of any other nation. The extra cost of labor on an American ship represents 5 per cent more on the capital investment than the labor on ships of other countries.

Exchange

Exchange, which is an important factor in foreign trade, did not receive so much attention at the convention this year as last, due largely to the fact that it is a more definitely known factor to-day, whereas it was largely speculative, so far as a solution was concerned, a year ago. Thomas R. Taylor of the Latin-American Division of the Bureau of Foreign & Domestic Commerce, made an elaborate presentation of the exchange situation, particularly with regard to Argentina, Brazil, and Chile, but what he had to say applies equally to practically all of the Latin-American countries. He looks for a rather restrictive market in this field for some time to come, which applies to practically all parts of the world as evidenced by other speakers. The possibility of trade with Europe did not receive any atten-

tion this year, Latin America and the Far East being the centers considered.

Taylor based his entire conclusions with regard to the present situation of Latin-American exchange on three fundamental causes which brought about the present collapse of exchange with these countries:

1. The change from a period of heavy excess of exports to a period of abnormally low excess of exports, or of excess of imports. The change in imports from these countries to the United States is indicated by the following figures; which show the amount in which the imports from these countries into the United States exceeded our exports to these countries.

1913	$185,000,000
1918	400,000,000
1919	358,000,000

During 1920 conditions reversed themselves and the balance of trade became unfavorable to them. In other words, they were exporting more than they were importing. In the last quarter of 1920 exports from the United States to Latin-America exceeded the imports from these countries by $69,000,000.

2. The second reason for the collapse of their exchange was that the flow of foreign capital to these countries ceased, Latin-American countries found their exports decreasing because of the sudden cessation of demand caused largely by the inability of Europe to buy and by the world-wide reaction in high prices leading to the so-called consumers' strike.

There was a heavy slump in the price of raw materials exported by these Latin-American countries. Sugar declined from 16 to 10 cents per lb. in the third quarter of 1920; coffee declined from 26 cents to 12 cents in the first half of the year; wheat declined from $2.58 per bu. to $1.80 per bu.; wool declined from 59 cents per lb. to 24 cents. This slump in prices together with the decline in volume caused a remarkable decrease in the export trade of these countries.

3. The third cause for the collapse of exchange is given as impaired credit. The currency in many countries has depreciated and in some government finance is not sound. Some of the countries have not yet paid interest charges on their debts. There is little accumulative reserve to fall back on in periods of depression such as the present as Latin-Americans are not a saving people, and much of the money earned easily was spent during 1919 and 1920.

The possibilities for an increased flow of foreign capital to Latin-American countries are fairly good. An American firm has recently closed a contract of $8,000,000 for the construction of a railroad in Bolivia. Marconi Limited has contracted with the government of Peru to operate the post office, telegraph and radio-telegraph services of the country. We have made loans of $30,000,000 to the State of Sao Paulo, Brazil, and $25,000,000 to Chile. Activities of this character indicate an improvement, but some of the countries confront a period of low receipts, and some of them will have a lower credit rating for the next year or two than they have recently enjoyed. The value of exports from these countries will increase on account of the quickened demand in Europe and the United States, which is already apparent, and also because of the large crops in Latin-America just now coming on the market.

Unsold Stocks

Although the trade between the United States and Asia increased five fold since 1914, there are in certain countries in Asia great stocks of unsold United States goods in ports due to cancellation of contracts. American importers, resident in China, have been literally swept off their feet and what is known as the mushroom trader and importer of the Far East has gone and stable business considers his elimination a good thing. After the war when there was no demand for our goods in Asia, belated shipments were pouring into that country in the greatest volumes. At present the markets of China and India are clogged with goods that must be sold at a loss and until these goods are sold the demand for new goods from this or any other country will be small. There are certain signs of improvement in trade with the Far East which will resume slowly. If China were on a gold basis instead of a silver standard, the Shanghai tale which in 1919 was at $1.22 and to-day is at 62 cents, would it is believed have a more stable character. This unit of value has never been controlled by the government and has always been subject to fluctuation. If the value of silver could be controlled, it would have a stabilizing influence, but there seems little possibility of this. Japan is on a gold standard, and India on what might be designated a gold exchange standard.

Notwithstanding present exchange rate in the Far East, M. A. Oudin, Far East representative of the International General Electric Co., believes the markets of the Far East constitute the world's greatest prize. He said that the number of American firms doing business in the Far East has decreased in contrast with the present activities of English and German firms, at a time when the necessity for aggressive American activity is greater. If American business expects successfully to compete with other nations in the Far East, it must exert itself primarily in three directions:

1—It must freely co-operate with the native business and local enterprises.

2—It must liberally invest its surplus capital in the development of industries, natural resources and public works.

3—It must insist that American economic interests be upheld by an American diplomacy as alert and vigorous as that displayed by other countries.

One way in which investments in China can be handled is through a group of American and foreign bankers known as the Consortium. This Consortium is prepared to loan money to China for public works, including railroads and other national purposes whenever China desires such assistance. The Far East is essentially a battleground on which many nations have engaged and probably will continue to engage in a hard struggle for commercial advantage, and not only must American residents doing business in the Far East be placed on a basis of equality with the nationals of other nations competing for that business, but the necessary arrangements for extended credits must be made.

Foreign Advertising

Advertising as a means of securing foreign trade was the subject of one group session. The policy of the home factory directly controlling the advertising copy and practically selecting the mediums in which it is to appear in foreign countries, as compared with leaving the writing and disposition of this copy in the hands of the distributors in the different countries, was advocated by Frederick Dickinson, advertising manager of the Hupp Motor Car Co. In the early days of the Hupp export experience the distributor, no matter in what country he did business, wrote his own copy and selected his own advertising media, and determined the size and extent of the advertising schedule, the factory dividing the expense on a basis of appropriating a definite amount per car shipped. This situation has been discontinued.

Under the new plan, the factory pays the entire cost of its advertising campaign. It makes up the list of publications. The reason for the change of policy was that the company wanted to be sure that the factory's story was being told regularly and steadily throughout the

market and told in its own words. The plan was to guard against misstatements, exaggeration and insufficiency of statement. Although opposition on the part of distributors to this plan was expected, none materialized. The Hupp company is still handling its foreign advertising in this manner, and is satisfied with the plan. The machinery and routine of the work is handled through an agency.

The necessity for studying the psychology of the different nations you are doing foreign trade with was emphasized by Fred Cardway, general manager of the Packard Export Corporation. Cardway is emphatic in the statement that no exporter should attempt to do business in any market until he knows thoroughly its distinguishing characteristics, its peculiarities and its sales potentialities. Psychological truths are independent of time, place or race. Human nature is the same the world over. All men are actuated by the same desires for food, clothing and shelter, so our problem in interpreting the psychology of the races of the world resolves itself into a matter of familiarizing ourselves with the racial surface differences that persist as a consequence of tradition, habit and geographical location. It is for the salesman to trace these varying qualities, these customs, morals, prejudices, fashions and social and national standards back to their source. Having studied these, he is then in a proper frame of mind to approach his prospects.

Foreign Trade Education

J. Walter Drake, Hupp Motor Car Co., and chairman of the Export Committee of the National Automobile Chamber of Commerce, Inc., recommended the establishment of a government training academy to be devoted exclusively to the preparation and education of men for the government foreign service. Such an academy would rank with West Point or Annapolis. This academy should have sufficiently large classes at all times to supply the necessary men for any possible demand on its service. A thorough and intensive course of training, both commercial and diplomatic, should be provided. There would be interchange of duties both before and after entering actual service, so that a man upon finishing his course would have acquired a sufficient knowledge of diplomatic usages to enable him to fill a consular place if necessary. There would be a fundamental training in the necessary requirements to fit the men to meet upon foreign ground the trained experts of other nations.

An academy of this character would do much to prevent the loss to the foreign service of men who through long training and experience have dropped out because of lack of adequate funds to carry on the work. The government foreign service requires special training and capacity in its men, which can only be produced through an academy of this character.

Drake believes that some movement of this kind is needed to correct the situation of to-day. We must come to a quick and full understanding of the fact that a proper and adequate organization of the government service is vitally necessary as a foundation for the new enterprise of the great world trade for which we are actively bidding. As a nation we must recognize and acknowledge the fundamental necessity of foreign trade. There must be built up in this country a public opinion that will force Congress to accept foreign trade as a part of our national policy and provide for its adequate support as for other essential parts of the government program. Diplomacy is inseparably linked with foreign trade. The government should have a foreign service adequate to fulfill its responsibilities for the success of the national enterprise. It is the duty of the government to establish the contact with prospective buyers through diplomatic relations; thereafter through the same means to insure the continuance of an attitude of friendliness and good will that the channels of trade may be kept free. The influence of diplomacy must be exerted from the very beginning and continued to the end.

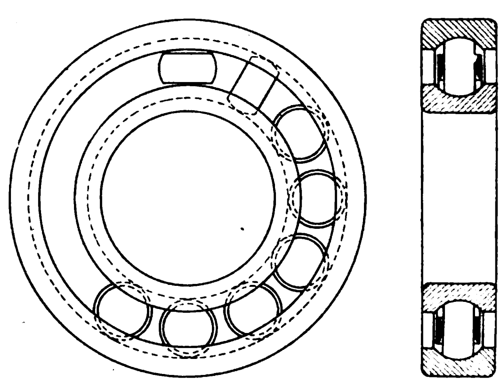
A New Disk Type Bearing

A NEW Swedish disk bearing for motor vehicle and other purposes has recently been introduced in this country. The disks are not cylindrical but, on the contrary, are central sections of an ellipsoid of revolution. The bearing comprises two race rings provided with grooves in which the disks run. It is possible to completely fill the space between the race rings with disks by inserting the disks with their axes perpendicular to the bearing axis and then swinging them around into their correct position.

One of the advantages claimed for the NKA bearing is that the disks are self guiding, that is, do not require a cage to guide them. A cage is used only because the disks must be held apart in order to reduce the friction. It is obvious from the sectional view of the bearing that a bearing of this type is capable of taking both radial and thrust loads, the latter, of course, to a far greater extent than the ordinary annular ball bearing.

It is claimed that this bearing known as the NKA can withstand as high speeds as an annular ball bearing, and that as the disks have less mass than balls of equal carrying capacity, the centrifugal force on the disks is less. High carrying capacity is obtained in this bearing by reason of the fact that the pressure on the disks is greatest at the center of the disks and very small at the edges, hence there is no tendency for the edges to become damaged. When the disk bearing is subjected to thrust loads the disk reaction automatically assumes a certain angle which depends on the amount of pressure.

Section and side view of the NKA disk bearing, latter showing method of assembling.



In these disk bearings the grooves of the races and the rolling surfaces of the disks do not have the same radius. The radius of the disk rolling surface is slightly smaller, being so calculated that when the bearing is under full load the entire width of the rollers is in contact with the bearing race. The manufacturers of this bearing are the Northern Ball Bearing Co.

Germany Reveals Extent of Automotive Exports

Statement issued by official statistical bureau tells the extent of trade for the first eight months of 1920. Figures show that trade reached many parts of the world. Domestic business is much hampered by taxes and operating costs.

By Benno R. Dierfeld

DURING the first eight months of 1920 Germany exported 14,024 passenger car and truck chassis. During the same period there were imported into Germany 122 passenger cars and 50 trucks.

This information is contained in the first statement issued by the German Statistical Office on automotive exports and imports. The figures cover the period from Jan. 1, 1920, to Aug. 31, 1920. The figures are not accompanied with descriptions that the American manufacturers would like to have for comparison, but they are done in the method of the German Statistical office.

Export—It is regretted that the export figures make no distinction between car and truck chassis and no distinction between a chassis and the complete vehicles. The only information available as to these shipments is the total number of vehicles, the weight and total value. The distribution to the several countries is compared, in the report, only by weight. To this is added an unofficial computation of percentage.

The total exports were 14,024 passenger car and truck chassis, listed at 28,764,500 kilograms, value 883,116,000 marks. A kilogram is 2.204 pounds. Owing to the variations of exchange during the period under discussion, an estimate of the value of a mark is impossible. The point of consignment of the chassis and the weight to each country during the period reported on is as follows:

Country	Kilograms	Per Cent
Belgium	658,100	2.30
Denmark	2,871,900	10.00
France	489,300	1.70
Great Britain	3,272,200	11.40
Italy	131,000	.40
Netherlands	6,025,700	21.00
Norway	1,235,900	4.30
Poland	394,600	1.30
Switzerland	4,160,500	14.50
Spain	5,655,600	19.70
Southeast Asia	520,800	1.80
United States	833,000	2.90
Central America	148,800	.50
South America	563,000	1.90
Other America	597,400	2.00
Other countries	1,206,700	4.30

The percentage of exports to the late enemy countries as shown by this table is interesting, to say the least. In the main, it may be said, that the trade has about followed the lead of the unofficial estimates made recently by American exporters, who have been watching Germany closely. Just what is meant by "Other" American countries after setting forth United States, Central America and South America is not clear.

Imports—In the accounting for imports into Germany, the figures are much more satisfactory, but these imports are so small as to be a negligible factor in trade. They are about what might be expected.

Of the 122 passenger car chassis imported, with a total weight of 263,000 kilograms, the division of the trade follows:

Country	Chassis	Per Cent
Austria	78	64
United States	10	08
Other countries	34	28

The 50 motor truck chassis are given a weight of 137,100 kilograms. The statistics are:

Country	Chassis	Per Cent
Austria	15	30
United States	22	44
Other countries	13	26

Motorcycles—The motorcycle trade is rather insignificant. The exports were 2839 machines of a total value of 19,657,000 marks. The country of consignment and the number of machines is:

Country	Number	Per Cent
Denmark	531	18.75
Netherlands	893	31.10
Sweden	372	13.30
Switzerland	537	18.95
Other countries	506	17.90

The imports were 17 motorcycles with a weight assigned of 2400 kilograms.

Parts—There is no mention of imports of parts during this period and the exports of parts are listed by weight, with no distinction as to kinds of parts or whether for cars, trucks or motorcycles. The total weight of these exports is 1,188,700 kilograms. The countries of consignment and the weight in kilograms follow:

Country	Weight	Per Cent
Belgium	170,800	14.00
Denmark	141,800	11.00
France	77,700	7.00
Austria	55,200	5.00
Poland	5,900	.50
Portugal	1,600	.10
Finland	27,400	2.40
Sweden	239,800	20.00
Switzerland	205,800	18.00
Spain	16,100	1.40
Southwest Asia	3,800	.30
United States	3,800	.30
Central America	3,200	.20
South America	8,900	.80
Other countries	226,900	19.00

Tires and Tubes—The exports in the rubber section of the automotive report show that tubes, tires and tire protectors were exported to the value of 36,838,000 marks, with a total weight of 249,200 kilograms. The country of consignment, with the weight to each country, follows:

Country	Weight	Per Cent
Denmark	51,800	20.80
Italy	10,300	4.20
Netherlands	52,500	21.00
Switzerland	73,000	29.20
Southeast Asia	13,100	5.30
South America	15,400	6.20
Other Countries	33,100	13.30

The imports are listed differently. First come 56,876 air tubes with a weight of 119,400 kilograms. The country of origin and number of tubes are:

Country	Number	Per Cent
Belgium	12,200	21.50
France	20,072	35.30
Great Britain	3,896	6.85
America	16,485	28.99
Other countries	4,223	7.36

Next come tire casings, of which there were 95,158 with a weight of 446,700 kilograms. The country of origin and the number of casings follow:

Country	Number	Per Cent
Belgium	19,083	21.01
France	18,209	19.12
Great Britain	10,744	11.30
United States	11,326	11.32
Other countries	35,796	37.25

These figures appear to reflect Germany's position as to raw materials for tires at the end of the war. It must be remembered that German tire exports before the war were a considerable amount.

Domestic Trade Retarded

The German automotive industry is practically without hope of important domestic business in the near future. This is partially due to the present 15 per cent sales tax, which operates double on the exchange of a used car for a new one, as the sale of the used car is taxed also. This has practically ended the exchange sales, for in the case of a trade of a used car on the basis of a $500 value, for a new car of $3000 value, the tax on the deal would be on a $3500 transaction.

In addition to this there is the severe wheel tax and the high price of fuel to be considered. Dealers also anticipate a very heavy tax on personal property. It is feared that with all of these taxes on the car, and the additions of heavy property taxes, there will not be much money left for motor cars. The sales tax on the purchase of a large car at present often amounts to 30,000 marks.

It is true that the sales tax law, which was passed as a luxury tax, operates to the benefit of the professional or business use of the car. But the tax collector is taking no chances. His method is to collect the entire amount of the sales tax and then remit parts of it from time to time, as he is convinced that the vehicle is used for the exempt purposes. The difficulty of this is that the physicians and others who would most benefit from this law have a very serious trouble in finding the money with which to pay the tax at the time of the sale.

This sales tax is not imposed on cars sold for export, unless the customer comes to Germany to make the purchase. If the car is bought in person in this country then it must pay the local luxury or sales tax.

Despite this feeling as to domestic trade, the automotive industry is proceeding with plans for an automobile show this fall, the dates being from Sept. 23 to Oct. 2. This show will be held in the large building erected in 1914 by the Automobile Manufacturers' Association and the Automobile Club of Germany, especially for a show that was planned for the fall of that year but which was not held because of the outbreak of the year. The building is a one-story structure, especially planned for industrial exhibitions and has a floor space of 20,400 square yards and is the largest exhibition hall on the continent. The show regulations as announced in part are:

As exhibits, only products of German firms, having their residence in the German empire, shall be permitted.

The announcements are to be delivered until May 15 at the Geschäftsstelle der Ausstellung (show office), Berlin, W. 9 Leipziger Platz 16. Announcements coming to hand later are taken into consideration, too, if space is available. However, for such announcements an additional rental of 25 per cent is required. The rent for a show stand, including the uniform stand equipment, is 500 marks for the square metre area and 250 marks for the square metre wall surface without area. All exhibits are distributed among the stands by lot within the following groups:

1. Passenger cars, shown by automobile factories.
2. Passenger cars, shown by body works.
3. Commercial vehicles of all kinds.
4. Motorcycles (if not shown together with motor vehicles).
5. Material, spare parts and accessories for motor vehicles.
6. Equipment for automobilists, clothing, cars, books, magazines, etc.
7. Special tools and machine tools, used in manufacturing of motor vehicles or their parts and accessories.

It is expected that this show will bring many new models to notice and that it will really show to the public the vehicles with which Germany hopes to compete for the world trade.

Ups and Downs of Industry

The story of the German automotive industry since the war is interesting. The second half of 1919 was a period of progress for the industry and in the first quarter of 1920 the industry had set itself for a period of progress, but in March came the reactionary commotion, called here the "Kapp-Putch," which caused a general economic and political confusion and was followed by a period of depression. To make the situation even worse, it was during this period that the serious change in the rate of marks took place. This financial flurry was accompanied by the rise of prices of cars on the domestic market and the complete loss of the export trade that had been well started.

It was not until September of 1920 that the automotive market again reached a stage equal to that of the end of 1919. During 1919 there had been a fair market for used cars and trucks, mostly army vehicles overhauled for civilian service. But this trade ended with the March break-up of business, and at the end of 1920 there the trade had not recovered. At the close of the year used car prices were about 30 per cent lower than at the beginning of the year and trucks were fully 45 per cent lower than at the end of 1919.

The trend of prices of passenger cars and trucks is well shown in the minimum prices at which a vehicle

can be listed for export for the purposes of collecting duties. The Government committee revises the minimum prices frequently. The Convention of Truck Manufacturers advises as to the prices of trucks. It must be remembered, however, that the prices quoted in these tables are the minimum, applying only to the cheaper cars and trucks of each class. The more carefully manufactured cars are listed at much higher prices. The prices given do not include export duty, but are the office price for an export shipment. Only three sizes of vehicles are mentioned for this comparison. The prices follow:

Passenger Car Chassis Value

	Engine Brake Hp.		
	15 Hp.	30 Hp.	45 Hp.
	Marks	Marks	Marks
Jan. 10, 1920	18,000	32,000	41,000
Feb. 4, 1920	31,500	56,000	71,750
May 1, 1920	39,375	70,000	89,687
June 11, 1920	40,000	75,000	95,000
Sept. 3, 1920	37,500	70,000	98,000
Dec. 21, 1920	40,000	77,000	92,000

Convention Values for Motor Trucks

	Load Capacity		
	2 Tons	3 Tons	4 Tons
	Marks	Marks	Marks
Jan. 10, 1920	60,000	70,000	75,000
Feb. 4, 1920	80,000	88,000	93,000
May 1, 1920	120,000	130,000	140,000
June 11, 1920	120,000	130,000	140,000
Sept. 3, 1920	102,000	112,000	122,000
Dec. 21, 1920	210,000	112,000	122,000

Licenses Are Restricted

Another very serious factor in the matter of sales has been the attitude of the Government toward the issuing of licenses. The owner of a motor vehicle is required to present a good reason why he should use his vehicle. The Automobile Dealers' Association published this estimate of the number of licenses in effect February 1, 1920. The percentages are a comparison with the number of permits in effect January 1, 1920:

Passenger cars	53 per cent
Motorcycles	42 per cent
Trucks	204 per cent

The increase in the number of trucks indicates the development of motor freight transport during the war, when the railways were required for military purposes. Toward the end of 1920 the number of licenses were increased. While more vehicles are permitted this year, the exact number is not published.

Fuel Prices

Fuel prices also have had a retarding effect, as can be seen by the following table of prices:

Gasoline-Consumer Prices for 100 Kilograms

	Delivering Firm	
	German-American Petroleum Co., Hamburg.	Rhenania, Düsseldorf.
	Marks	Marks
December, 1919	505.00	590.00
January, 1920	510.00	528.70
February, 1920	660.00	814.00
March, 1920	876.50	956.00
April, 1920	800.00	823.00
May, 1920	937.00	1,062.00
June, 1920	772.00	1,062.00
August, 1920	745.50	804.00
September, 1920	745.50	775.00
October, 1920	745.50	775.00
November, 1920	761.50	793.00
December, 1920	761.50	793.00

Benzol-Consumer Prices per 100 Kilograms

	Marks
May 17, 1919, to Jan. 5, 1920	142
Jan. 6, 1920, to May 19, 1920	310
May 20, 1920, to end Feb., 1921	560

The excessive sales tax, 15 per cent on passenger cars, whether the vehicle is a new or a used car, is a severe sales resistant. But this is paid only once, and a more serious factor is the wheel tax levied by the Federal Government. This tax, unlike the sales tax, applies alike to all vehicles, whether used for commercial, professional or recreation purposes. The present cost of operating a car in Germany is shown in the following table, which is accepted in this country as an average of all costs:

Operating Costs per Kilometer

	Marks
15 B.hp. passenger car, without driver	3.00 to 3.50
45 B.hp. passenger car with driver	7.00 to 7.50
4-5 ton truck with driver	9.00 to 9.50

The existing decrees of the Government have practically excluded foreign cars from the German market.

A Battery Meter

An instrument which when mounted on the dash of an automobile and properly connected to the electric system shows the operator not only at what rate the battery is charging or discharging, but also the state of charge of the battery, has been placed on the market by the Edward A. Cassidy Co., Inc., under the name of Cell-O-Meter. It is of the same size as an ordinary dashboard ammeter and is designed to take the place of the latter on the instrument board. The connections are the same, except for one extra connection from the Cell-O-Meter to ground.

The Cell-O-Meter embodies two distinct instruments and has a two-part dial. On the left side is the ordinary ammeter scale, showing both charging and discharging current. The right-hand half of the scale, marked "Battery Condition," is divided into three sections; the red section denotes that the battery is nearly discharged and should not be used; the yellow section denotes that the battery is about half charged and is safe to run with, while the green section shows that the battery is fully charged.

Ordinarily the instrument acts as an ammeter, but by pushing a button on the dial the battery condition indicating mechanism can be brought into action. The instrument evidently operates on the voltage measurement principle. It is claimed that when this instrument is fitted it is not necessary to use a hydrometer. At present the instrument is made in four models and the model to be used depends upon the battery voltage and ampere-hour capacity.

S. A. E. Summer Meeting Program Includes Many Important Papers

Five professional sessions and one business session, together with Standards Committee meeting will occupy greater part of last week in May, but allow ample time for usual sports and recreation. Aeronautics, highway transportation, research and standardization the important subjects.

DEFINITE announcement concerning the time and nature of the several sessions to be held during the semi-annual meeting of the Society of Automotive Engineers at West Baden, Ind., May 24 to 28, has recently been made and is summarized below. The convention will open, as usual, with a meeting of the Standards Committee, which all members and other engineers interested are invited to attend. Many important recommendations formulated by the various divisions of the committee will be considered. In the evening of the same day, Tuesday, May 24, the usual business meeting will be held. This will include a brief address by President Beecroft and election of members of the Nominating Committee.

The morning of Wednesday will be given over to simultaneous sessions devoted, respectively, to Highway Transport and to Aeronautics. The need for Federal legislation and other phases of aeronautics bearing upon commercial air transportation will be considered, while existing types and trends in aircraft engines will be discussed from the standpoint of military and commercial requirements.

Wednesday, Thursday and Friday afternoons and evenings will be given over to sports and recreation, for which elaborate provision has been made. Many members will be accompanied by their wives, and the program of sports includes many events for ladies.

Thursday morning is to be devoted to a general research session, at which two of the papers will contain descriptions of the facilities possessed and methods followed by two research organizations, those of the University of Michigan and the General Electric Co. The two other papers will deal with subjects of immediate practical interest to all automotive engineers. One of these will discuss lubrication, the author, C. W. Stratford, of the Associated Oil Co., being well known because of the extensive research and development work he has conducted in connection with lubricants and lubrication for automotive engines. The remaining paper at this session has been prepared by Herbert Chase of AUTOMOTIVE INDUSTRIES' Editorial Staff and deals in a comprehensive way with Practice and Theory in Clutch Design. Over twenty-five designs of American and British clutches are illustrated and discussed, the advantages and disadvantages of the various types pointed out and the principal design factors outlined.

The Combustion Session, to be held on Friday morning, May 27, will include three papers, at least two of the authors being well known among engineers who have made a study of automotive engines and their combustion processes. Dugald Clerk is prevented from attending the meeting, but his paper, summarizing his notable achievements in gas engine work over a period of nearly forty years, will be presented in his absence. Harry L. Horning, whose previous papers on combustion chamber design will be well remembered, is to present many interesting facts regarding the influence of combustion chamber shape on turbulence and the effect of turbulence on combustion and engine performance. The physical and chemical characteristics of flame are not generally understood by engineers, though they are important to a clear understanding of combustion phenomena. The paper on Flame by C. A. French should, therefore, be timely and instructive.

The concluding session of the meeting will be held on Saturday morning and be devoted to Fuel Research subjects. The Bureau of Standards will, as usual, contribute valuable information, this time through the medium of a paper on the Elements of Automobile Fuel Economy by W. S. James, with appendices by Dr. H. C. Dickinson and S. W. Sparrow. This paper contains much valuable basic information which should be studied and applied by all automobile engineers. A second paper, showing what can be done in the way of improving the fuel economy of an automobile engine by improving manifold design, is to be presented by George P. Dorris. F. C. Ziesenheim, whose contributions to these columns will be favorably remembered by readers of AUTOMOTIVE INDUSTRIES, will discuss the Development of a High Compression Oil Engine, a subject which he has long been giving intensive study.

The program, except the business and standards committee sessions, is:

Aeronautic Session, Wednesday, May 25, 10 A. M.

Mead, G. J. and L. E. Pierce—Aviation Power Plant Development.
Clark, V. E.—Air Transportation and the Business Man.
Philbin, S. H.—Need for Federal Control in Commercial Aviation.

Transportation Session, Wednesday, May 25, 10 A. M.

Goldbeck, A. T.—The Vehicle and the Road.
Tilden, C. J.—Transport Engineering Education.

General Research Session, Thursday, May 26, 10 A. M.

Hawkins, L. A.—Industrial Research.
Stratford, C. W.—Lubrication.
Chase, Herbert—Practice and Theory in Clutch Design.
Lay, W. E.—Co-operation in Research.

Combustion Session, Friday, May 27, 10 A. M.

Horning, H. L.—Turbulence in Theory and Practice.
French, C. A.—Flame.
Clerk, Sir Dugald—Cylinder Actions in Gas and Petrol Engines.

Fuel Research Session, Saturday, May 28, 10 A. M.

Ziesenheim, F. C.—Development of a High-Compression Oil Engine.
Dorris, G. P.—Manifold Development.
James, W. S.—Elements of Automobile Fuel Economy.

New Life for Roadster Body Design

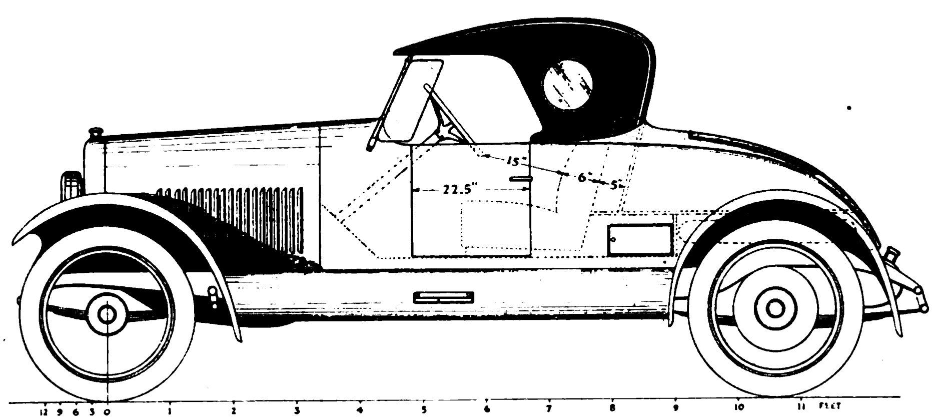
This article describes a typical roadster of the new design brought out this year. It is confined to a seating capacity of two persons and is rather massive in comparison with older designs. The top is permanent, while steps replace the usual running-board. Extra tire is carried in compartment.

By George J. Mercer

THE current year has brought what may be termed a rebirth of the roadster. During the last few years interest in the roadster has been a constantly decreasing factor. Each builder made a roadster to suit his own trade, without much regard to what his competitor was doing. Designers in general seemed to be giving considerably less attention to roadsters than to any other model.

The lack of interest in the roadster can probably be attributed largely to the increased use of the four- and five-passenger touring body. This tended to discount the use of the roadster and to center designing attention on other models.

New types of roadsters which were exhibited first at the New York show this year, however, indicate a new life for this body model. The new designs are strictly limited to two seats in most cases, although three seats are provided in rare instances. This makes the roadster a distinct model and takes it out of conflict with the four- and five-passenger touring models.



An up-to-date design of roadster. Note space provided for carrying spare tire.

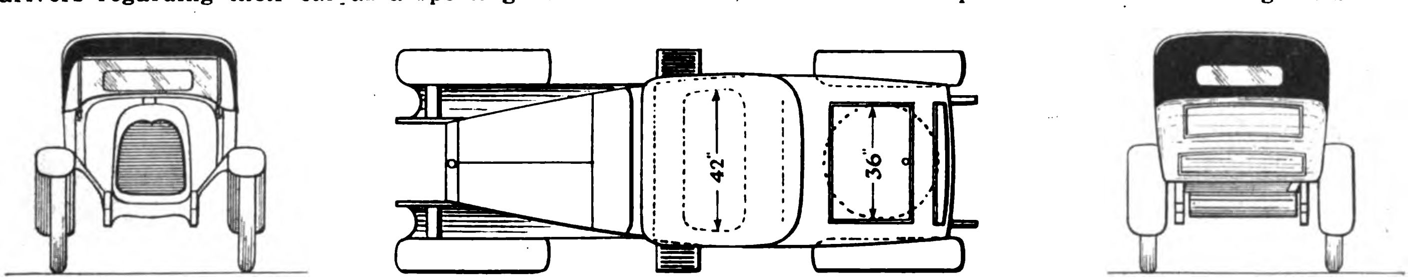
A typical roadster of the new type is shown in the accompanying illustration. The principal change from the older roadster models is comprised in the more massive construction and increased comfort of the present models. The sides are high, the seats are low and the height of the seat-back has been increased. Thus the rider is given a genuine sense of being hugged in the seat. The seat close to the floor meets with the approval of those desiring this type of car, since they are usually drivers regarding their car as a sporting as well as a transportation vehicle. Making the seat-back high is an easy matter, of course, when the seat itself is placed close to the floor.

The rear carrying compartment is made as commodious as possible. The line in the center is almost to the top of the seat-back. It is continued in a generous sweep to cover all the chassis frame, and is free of gasoline gage and filler. The top view shows that the width of this rear end is made to cover the inner line of the mudguards and that there is a wheel house, as with a touring body.

The appearance of this large rear is much better than one would think when looking at a finished body before it is mounted on the chassis. Formerly the writer favored a rear end the top line of which was nearly horizontal. Now that the width has been increased, however, the line as illustrated presents an excellent appearance; especially when the extreme back end is wide enough to just lap over the inner line of the guard.

The appearance from the side indicates that the top line of the body side is featured to some extent on the corner of the rear and forms a side panel line to the rear, as indicated. The corner where the top and side sheets blend is of small radius, and, as the top line of the body has a small radius to the outer edge, there is almost a true line from body top to back.

The extra tire is carried usually in supports at the back and in plain view, but where there is abundance of room, as in the design shown, the tire can readily be carried in a compartment. This method gives better



Front, plan, and rear views of the roadster illustrated above and described in the text.

protection all around. The floor, as indicated by dotted lines, is above the tire space, while the door at the side gives access to the small separate compartment forward.

The division back of the seat is similar to that in the average coupe; a loose lid gives access and it is a handy place to carry small parcels. But the primary reason for adding the space back of the seat is for the better appearance of the top. The top is given length from back to front and thereby makes the whole car look lower. It is surprising to note how much improvement is made by the addition of this 6 inches to the length of the top. The space thus provided is convenient for carrying the storm curtain and allows room for parcels as well.

The top in the design shown has been made permanent. We have not yet reached the point of having genuine approval for a stationary top even on touring cars, though it is quite general. But the trend is slowly marching in that direction, for a large number of such cars are used with the top up most of the time. The permanent top has the disadvantage of furnishing increased area for wind resistance, but, on the other hand, the appearance remains good for a longer time. Windshield side wings should be used with a top, as shown. The side window is round, because such construction better simulates a Victoria top feature.

The mudguards shown indicate the general design adopted. On some of the new cars there is a tendency to supersede the runboard with steps. This has been done to a limited extent, of course, for several years, but there are more cars so equipped at the present time than ever before. Several new car manufacturers, not yet hampered by tradition, are using this as regular equipment. For the roadster, steps are ideal, as a better vision of the road is allowed, and the car has more the sport-type appearance than with the runboards.

The shield meets both the front and rear guards, and the step is a large grill, 12 by 14 in. long by 10 in. wide. It is usually a casting of aluminum composition and is bolted flat against the splasher, behind which are brackets supported from the frame.

The doors in the rear compartment are always the cause for disappointment on account of water leaking through when the car is washed. This difficulty is hard to overcome, but a minimum of leakage can be assured if the opening has a combing or lip of the metal projecting ¼ in. above the level of the metal sheet, with the lid or door cupping over this, and with rubber tubing or flexible packing to make the connection tight.

The hinges for these lids are the concealed type, and the spring box lock is generally used.

Electrically Heated Japanning Ovens

An electrically heated japanning oven which possesses several features of general interest has been installed at the McCord Manufacturing Co. plant.

The oven is of the continuous conveyor type, and is double-decked, having two compartments, one over the other. The work after being dipped is carried on a conveyor through the lower compartment, then back and through the upper, the exit of which is just above the entrance to the first. Both compartments have the same dimensions, 10 ft. 4 in. wide by 5 ft. 10 in. high, by 60 ft. 10 in. long. It is equipped with General Electric Co. heaters, and automatic control, the total connected load being 324 kw. at 220 volts, three phase, 60 cycle. The baking capacity is 3000 lb. of radiator shells, the time being 45 minutes from extrance to exit. The oven is a Young Bros. installation.

The heat is divided into three zones, regulated by automatic control panels located just above the entrance to the ovens (Fig. 1). The lower compartment is equipped with comparatively few heaters, which are concentrated at the rear end. This gives a preheating zone in the forward end through which the work passes, before being subjected to the maximum heat of the compartment, 250 deg. F. The work is then carried to the upper chamber, which is equipped with heating units for its whole length. The temperature in this compartment is 450 deg. F. which is required to complete the bake.

An interesting explanation of why farm tractors are not built with four-speed transmissions like many automobiles was given in a popular lecture recently. The speaker said that the maximum drawbar pull which could possibly be obtained from a tractor depended upon its weight, and this determined more or less the lowest speed to which it was practical to gear a tractor. At very much higher speeds the tractor had so much unnecessary weight that it became an impractical proposition, and this was the reason that these higher speeds were not provided.

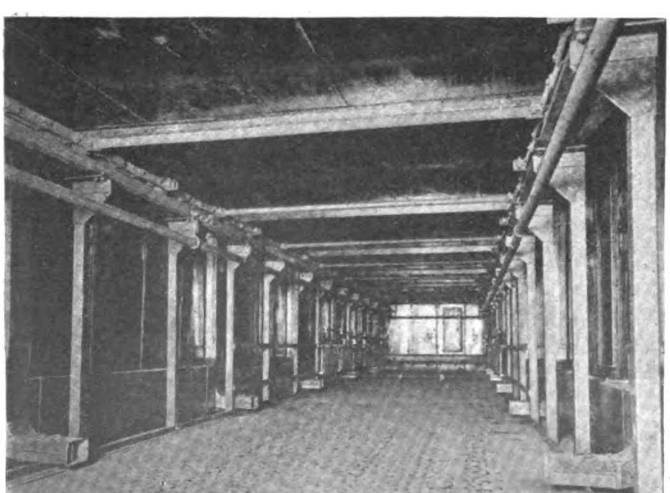


Fig. 1—Lower compartment and entrance end to first heating zone. Continuous conveyor japanning oven. Electric heaters shown in background.

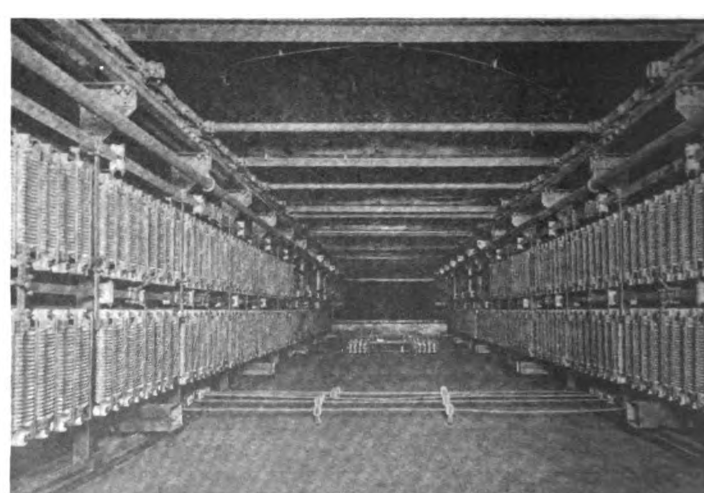

Fig. 2—Upper deck of continuous conveyor japanning oven looking in direction of exit end. Automatic temperature control instrument shown in foreground.

The Influence of Various Fuels on Engine Performance

Part III

This instalment of the report on the author's investigations gives definite data regarding the maximum temperatures and pressures at the end of compression which can be used without resulting detonations. The use of inert gas as a diluent to prevent detonation is also covered.

By H. R. Ricardo*

IN order definitely to establish the relative importance of temperature and pressure at the end of compression upon the tendency to detonate, hexane was evaporated in a small steam boiler and admitted to the carbureter. The temperature of the entering gases was then controlled by means of the electric heater fitted in the carbureter air intake passage. When working in this manner it was found that the compression ratio could be raised by 0.1 for every 10 deg. C (18 deg. Fahr.) drop in temperature from 70 deg C. (158 deg. Fahr.) to 30 deg. C. (86 deg. Fahr.), the corresponding ratios being from 4.8:1 up to 5.2:1.

This test is important, because it establishes a definite relationship between the temperature of the charge and its tendency to detonate. Nor is the issue confused by any question of a further drop in temperature after entry to the cylinder due to the latent heat of unevaporated liquid. So long as no evaporation takes place within the cylinder the temperature of compression at any given speed—and cylinder temperature will always bear a definite relationship to the temperature of the entering fluid over the range of compression ratio explored—the final compression absolute temperature may be taken as approximately 1.7 times the absolute temperature at the commencement.

Thus an increase in the temperature of compression of 17 deg. C. (30.6 deg. Fahr.) necessitated a drop in the compression ratio of 0.1.

If, as is generally supposed, detonation were a function of temperature alone, then the variation in compression ratio corresponding to the variation in inlet temperature would have been nearly five times as great, for the difference between the final compression temperatures at compression ratios of 5:1 and 6:1 is only 38 deg. C (68.4 deg. Fahr.) if the inlet temperature is constant.

These direct, and other less direct experiments, all confirm the statement made previously that the detonation point of a fuel is more closely dependent upon compression pressure than upon compression temperature.

Relationship Between Detonation Point and Spontaneous Ignition Temperature

It has generally been assumed that the detonation point of a fuel would be dependent upon its spontaneous ignition temperature as determined in air or oxygen. While, broadly speaking, the results showed that the temperature of spontaneous ignition of a fuel might be taken as a very approximate indication of its tendency to detonate, it was found to be quite unsafe to rely upon this relationship.

Table VI shows the compression ratio at which certain samples were found just to detonate. The table also shows the temperature of spontaneous ignition, in air and oxygen at atmospheric pressure, as determined by Harold Moore.

If detonation were a function of compression temperature alone, then a closer relationship might be looked for between the temperature at which detonation commenced and the temperature of self-ignition. In any event, however, the conditions obtaining in an engine cylinder in which the gases are in a state of violent turbulence are very different from those under which the tests for spontaneous ignition were carried out.

It seemed probable that the temperature of spontaneous ignition of a fuel would form a tolerably true indication of its readiness to pre-ignite, as distinct from the tendency to detonate. This seemed to be borne out in the case of those fuels which pre-ignite without preliminary detonation, such as the members of the aromatic series, methyl alcohol, etc., but the following experiments with mixtures of the paraffin series and carbon bisulphide tended to corroborate this theory. Experiments on the self-ignition temperature of carbon bisulphide when ignited as a stagnant mixture by adiabatic compression showed that this fuel would ignite spontaneously at a temperature of about 275 deg. C. (527 deg. Fahr.). When this fuel was tested alone in the variable compression engine heavy pre-ignition occurred at the lowest compression ratio, and at the lowest inlet and water temperature, with the result that it could not be used at all.

The pre-ignition was, however, unaccompanied by any trace of detonation. When carbon bisulphide was mixed with aromatic free gasoline in proportions up to and even exceeding 50 per cent, it was found to raise the detonation point as compared with that of the gasoline alone. A mixture of aromatic free gasoline and carbon bisulphide in equal parts was found to detonate with a compression ratio of 5.15:1, while pure aromatic free gasoline detonated at a compression ratio of 4.85:1. So far, therefore, as detonation is concerned, carbon bisulphide may be said to have a positive toluene value of about 18 per cent. When running with such a mix-

*From a preliminary report on research work conducted by the author and other investigators for the Asiatic Petroleum Co. and published in *The Automobile Engineer*.

ture at a compression ratio of 5.15:1 there was no trace of pre-ignition, and it was not until the proportion of aromatic free gasoline was still further reduced that pre-ignition first became apparent.

The inference to be drawn from these experiments is that carbon bisulphide, while pre-igniting very readily, will not detonate, whereas any paraffin gasoline will detonate, but will not readily pre-ignite. Tests carried out on the special machine designed for ascertaining the self-ignition temperature of fuels when ignited by adiabatic compression showed that carbon bisulphide ignited under compression at a gage pressure of about 185 lb. per square inch and a compression temperature of about 275 deg. C. (527 deg. Fahr.), while the aromatic free gasoline ignited under the same conditions at a gage pressure of 320 lb. per square inch and at a temperature of 353 deg. C. (668 deg. Fahr.). The initial temperatures before compression were 15.0 deg. C. (59 deg. Fahr) and 15.6 deg. C. (60.1 deg. Fahr.) respectively.

In the case of those fuels which pre-ignite without preliminary detonation, it was found very difficult indeed to determine the pre-ignition point, because, in practice, this clearly depends largely upon the temperature of the exhaust valves, sparking plug electrodes and other insulated parts within the combustion chamber. As might be expected, variations in the design, or in even the condition of the sparking plug, exerted so great an influence upon the tendency of the fuel to pre-ignite as to render anything more than a very approximate determination impossible.

It is hoped, later on, that the results of tests of the spontaneous ignition temperature and pressure, when both temperature and pressure are raised by the adiabatic compression of a stagnant mixture, will be sufficiently advanced to enable them to be fully dealt with, and their relation to the detonation point shown.

It may be argued from the test results given that so far as existing engines are concerned, no advantage would be obtained from the use of a fuel of high toluene value, because very few engines, other than aircraft, have a compression ratio as high as 5:1 which in the variable compression engine requires* a toluene value of only 5 per cent.

It must be remembered, however, that in this engine every effort has been made to reduce detonation. The form of the combustion space is the most efficient practically obtainable. The charge is ignited from two points at opposite sides of the combustion chamber, and the time of the passage of the spark perfectly synchronized. Turbulence of the charge in the cylinder is at a maximum, and there are no pockets or recesses where unburnt gas can become entrapped and detonated.

Finally all comparative tests were run at a speed of 1500 r.p.m. corresponding to a piston speed of 2000 ft. per minute.

In the ordinary car or commercial vehicle engine these ideal conditions do not apply, but on the contrary the combustion chambers are in many cases so designed as to encourage detonation. Check tests were from to time made on various standard engines on different test beds at the laboratory. One engine, designed and built by one of the best known makers of commercial vehicle engines, afforded an excellent illustration of the effect of combustion chamber design upon detonation. Had the designer of this engine set himself the task of trying to induce detonation, he could hardly have been more successful. This particular engine had a compression ratio of 3.95:1, corresponding to a compression pressure of only 78 lb. per sq. in., yet the engine detonated alarmingly even on a fuel of toluene value 10 per cent, while the variable compression engine using the same fuel would run perfectly smoothly, and at maximum efficiency,

Table VI.

	A	B	C	D		E		F		G	
		Detonation Point in the Variable Compression Engine				Self-ignition Temperature as Determined by Adiabatic Compression with Air		Self-ignition Temperature at Atmospheric Pressure as Determined by Moore

Notes.—The sign * denotes that the value given for compression could not be exceeded owing to pre-ignition occurring before audible detonation.

Column D. The compression temperatures given in this column are calculated, taking into account the fall or rise in temperature due, respectively, to the latent heat of evaporation of the fuel on the one hand and a constant heat input of 65 B.T.U.'s per minute on the other.

Column E. The figures given in this column are the temperatures at which samples of the fuel were found just to ignite spontaneously when a mixture of fuel and air of a strength to give complete combustion was suddenly compressed, without initial turbulence, the ratio of compression being adjusted until self-ignition just occurred. This machine, which will be described later, has only recently been brought into operation and some uncertainty still exists as to the true value for the exponent of the compression curve. There is no reason, however, to doubt the relative accuracy of these figures.

Columns F and G. The figures given in these columns are taken from Harold Moore's paper on the Spontaneous Ignition Temperatures of Liquid Fuels for Internal Combustion Engines read before the Society of Chemical Industry, December 1st, 1916.

with a compression ratio of 5:1. To enable the particular engine referred to to run smoothly on any fuel having a toluene value of less than 20 per cent, it was necessary to employ an over rich mixture and to considerably retard ignition, sacrificing both power and economy.

It is estimated that the majority of engines now in use can run at the maximum efficiency on a fuel of toluene value of from 15 to 20 per cent.

In the summer of 1919 the Shell Marketing Co., realizing that the existing methods of specifying the quality of their motor spirit by determination of the specific gravity and boiling-point range, while affording useful information in certain respects, were of minor importance compared with toluene value, inaugurated the system of so blending their shell spirit as to give a high uniform toluene value. During this period a census was taken of the experience of fifty users of a total number of nearly 200 cars and commercial vehicles. An analysis of this census showed an average increase in the mileage per gallon of no less than 17 per cent as compared with other brands of gasoline, while over 80 per cent of the users canvassed volunteered that they noticed a very marked increase in power on hills, due clearly to the fact that absence of detonation enabled them to run at slow speeds with an efficient ignition timing. Guided by these results, the Shell Marketing Co. have determined to maintain a definite toluene value standard for their Shell spirit, and they now always blend this brand with this object in view.

This practical experiment proved strikingly that it is the tendency of a fuel to detonate, which in practice controls the efficiency and power output obtainable from it, even when it is used in the relatively low compression engines such as are general to-day.

Tests carried out by the Royal Aircraft Establishment and most of the manufacturers of aero-engines have shown also that both the power output and economy of aero-engines can be increased by the addition of benzol to fuels of low toluene value, not because it contains greater internal or potential energy, for, as will be shown later, it does not, but simply because the addition of benzol checks the tendency to detonate and so permits of the more efficient use of the fuel. The Air Ministry's existing specification for an aircraft spirit insists upon a gravity and boiling-point range which limits the toluene value to from 12 to 14 per cent, and necessitates a low aromatic content for the fuel. Such a fuel will cause violent detonation in some of the most important existing aircraft engines. The aromatic content, therefore, is often raised by the addition of benzol, which is composed chiefly of benzene and which, curiously enough, is the heaviest and least effective member of the aromatic group. Such a state of affairs illustrates how little the essential characteristics of a good fuel were understood.

It will be shown later that, compared with the question of detonation, all other considerations and differences, in so far as they control the power output and efficiency, sink into insignificance.

Certain rigid requirements must, of course, be fulfilled. The fuel must contain at least a minimum proportion of highly volatile constituents with a high vapor tension in order to facilitate starting; these, however, can be added to any fuel, and need not influence appreciably its toluene value. Again, the final boiling point must not be so high that liquid fuel will condense upon the cylinder walls, and so ultimately find its way into the crank chamber. These and other points will be dealt with later on, but it is well to emphasize at this stage that, compared with the tendency of a fuel to detonate, they are of secondary importance.

In the course of the investigations upon the subject of detonation certain other experiments were tried, some of which are of sufficient interest to be worth recording.

Since detonation is presumably a function of the rate of burning of a fuel, experiments were carried out with a view to ascertaining how far the efficiency could be improved, when the rate of burning was controlled by means other than varying the composition of the fuel. For this purpose the addition both of cooled exhaust gases and of water was employed.

It was found that by the addition of cooled exhaust gases to the standard aromatic free petrol, detonating normally at a compression ratio of 4.85:1, the compression could be raised up to 7.5:1, or even higher, without detonation or pre-ignition. This increase of ratio corresponded to an increase of compression pressure of from 105 lb. per sq. in. to 203 lb. per sq. in. gage. In these tests the variable compression engine was run up on the standard aromatic free gasoline, until all con-

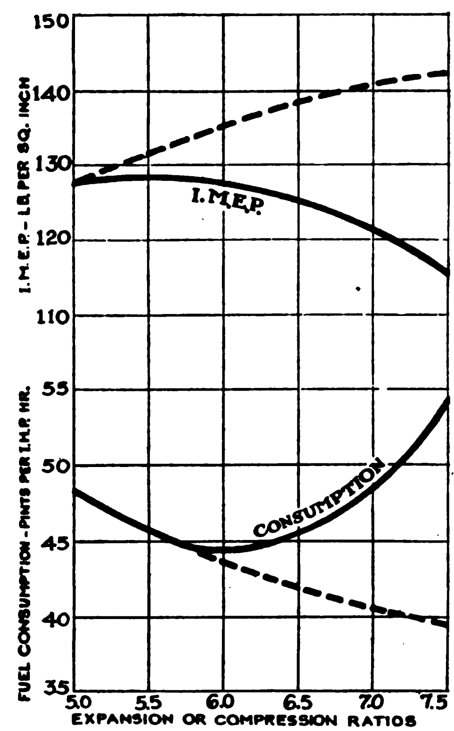

Fig. 7
Full line curves show the results with a fuel of low toluene value with cooled exhaust gas added. Dotted lines show the corresponding values of I.M.E.P. and of fuel consumption for a fuel of high toluene value requiring no dilution with inert gases

ditions had become normal. The compression ratio was then raised till the detonation point was reached, when readings of torque and fuel consumption were taken, the mixture strength being adjusted until the most economical proportions had been found. A cock admitting cooled exhaust products to the air intake of the carburetor was then slightly opened and the compression raised until detonation again became apparent, when readings of torque and fuel consumption were taken at the higher compression ratio. The procedure was repeated at frequent intervals at compression ratios ranging up to 7.5:1, in each case just sufficient exhaust gas being admitted to check detonation. The results obtained are shown in Fig. 7, in which the full lines show the torque in terms of indicated mean pressure and the dotted lines show the torque obtained without exhaust gas added, at the same compression ratios and with a fuel of the same

energy content but of sufficiently high toluene value to withstand the highest compression. The divergence between the two mean pressure curves indicates approximately the proportion of exhaust products required to check detonation at each compression ratio for aromatic free gasoline. The lower curves show, in full lines, the fuel consumption in pints per i.h.p.-hour, with the exhaust gas added, and in dotted lines, the consumption obtained with a fuel of exactly the same calorific value per pint, but of sufficiently high toluene value to need no exhaust gas added.

It will be observed that in spite of the addition of inert gases, the net power increases with the increase of compression up to a ratio of 5.5:1. This is due clearly to the higher efficiency of the "air cycle." Above 5.5:1 the quantity of inert gas required to check detonation more than balanced the improved efficiency due to the greater expansion ratio, and the power output declined again. The economy increased with increase of compression up to 6:1, in spite of the high specific heat of the exhaust products, but above this compression it declined rather rapidly, due in part to the rapidly increasing proportion of exhaust products required, and in part no doubt due to incomplete combustion.

Similar tests were carried out using steam in place of cooled exhaust gases. The results obtained were generally similar in characteristics. It is hoped to carry out further tests with nitrogen and carbon dioxide.

The results given are interesting in that they indicate clearly:

(1) That under normal conditions pre-ignition, in the case of ordinary gasoline containing a substantial proportion of members of the paraffin series, is always brought about by persistent detonation.

(2) That if detonation be prevented, pre-ignition will not readily occur, even though the compression pressures be raised to double that permissible under normal conditions.

(3) That detonation is a function of the normal rate of burning, and that if this be delayed by employing inert gas to act both as a brake and as a cooling agent, much higher compression pressures can be used.

Another experiment, also of some interest, was carried out in order to determine the compression pressure at which detonation takes place when a high compression is used and the engine is throttled.

Experiments with Compression Varied by Throttling

For these tests the same standard aromatic free gasoline was used, and after preliminary running at full throttle, the latter was partially closed, and the compression ratio raised to say 5.5:1. The throttle was then very gradually opened until detonation just became apparent, a reading of torque was taken, the throttle was locked securely in position, and the supply of fuel cut off; the engine was then driven by a motor at the same speed, and the actual compression pressure recorded by means of a modified form of Okill indicator, which was found to give very accurate readings. The same procedure was repeated at a number of different compression ratios varying up to 7.5:1, and the results obtained are as shown in Fig. 8.

The full lines indicate the observed results with varying throttle opening, and the dotted lines show what would have resulted if the fuel had permitted of full open throttle being used at all compressions. It will be observed that while under these conditions of throttling the indicated mean pressure, and therefore the power output, naturally falls very rapidly, the actual compression pressure at which detonation first became apparent is nearly constant. Owing, however, to the relatively small proportion of charge taken in at the higher speeds, the proportion of exhaust gases in the mixture is slightly greater at the higher compression, and this no doubt accounts for the fact that the pressure at which detonation commenced is higher at the higher compression ratios, instead of slightly lower as would otherwise be expected due to the higher compression temperature.

As a practical and ready means of determining the toluene value of a fuel, it is interesting to note that the new aniline test employed by chemists for determining the aromatic content of a fuel responds also to the naphthene content, and therefore this test affords a fairly accurate measure of the tendency of the fuel to detonate. The reason for this is shown by reference to Table III (which was printed in the preceding article on this subject), giving, for various fuels, their observed toluene values and also their approximate compositions. It may be seen from this table that the average toluene value of the paraffins present in petrol is roughly — 10 per cent. The average for the naphthenes is + 30 per cent.

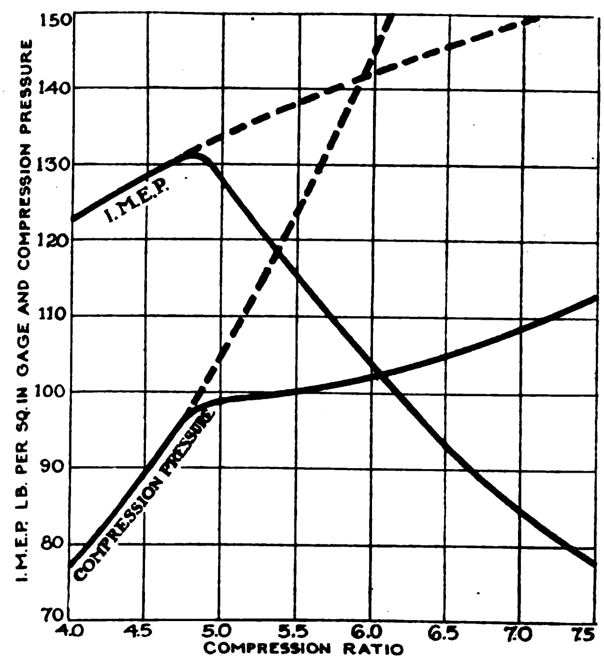

Fig. 8

The full lines show the indicated mean pressure obtained and the corresponding compression pressure (taken by modified Okill gauge) for varying compression ratios, and the throttle closed just sufficiently to prevent detonation of a fuel of low toluene value. The dotted line continuations show what would have been the resulting mean pressures at the various ratios had the toluene value been sufficiently high to admit of full open throttle at the highest compression ratio

The average for the aromatic is + 75 per cent—the toluene value of benzol being 67 per cent, of toluene 100 per cent and of xylene 85 per cent.

Although the results obtained from this series of investigations into the factors controlling detonation permit of certain fairly definite conclusions being drawn, the writer feels that much still remains to be done, for many discrepancies still remain to be cleared up. The following conclusions and inferences may, however, safely be drawn:

(1) The one outstanding factor, limiting both the power output and the efficiency obtainable from any fuel, is the tendency of the latter to detonate. This controls not only the compression ratio which can be employed, but in most cases it controls also the efficiency at which the fuel can be burnt, even at relatively low compressions.

(2) The tendency of a fuel to detonate appears to be a direct function of its normal rate of burning.

(3) No evidence of any kind has been adduced to show that the normal rate of burning of any fuel can be too low. This point will be discussed further when dealing with the power and efficiency obtainable.

(4) Of all the constituents of natural gasoline the most effective in checking detonation is toluene, followed by the other members of the aromatic group.

(5) Although compared with the other constituents the aromatic series have a somewhat lower calorific value per lb. (but not per gallon), the gain in efficiency due to their presence, even in quite small quantities, is so large as to render the small difference in heat value insignificant.

(6) The classification of a fuel by its specific gravity and boiling point applies only when the fuel is composed entirely of pure paraffins. No such fuel is, or ever has been, available outside a chemical laboratory.

(7) Any specification for a fuel should be so drawn as to encourage the inclusion of as large a proportion of the aromatic series naturally present in the crude petroleum as possible.

(To be continued)

Development of Aeronautical Engines by the Army and Navy

DEVELOPMENT of certain types of engines by the Army and Navy Air Services has been recently approved by the Secretary of War and the Secretary of the Navy upon recommendation of the Aeronautical Board.

Class (a)

Of mutual interest to the Army and Navy Air Services.

50-60 HP.—An engine of this power is available but further development of this type has been assigned to the Navy Department.

350 HP. Air-Cooled Radial Engine.—This engine is placed in this class on account of the maneuverability that can be given to an aircraft equipped with it, reduction in area of vulnerable parts, and a wide range of atmospheric temperature in which it will probably be capable of operating. The development of this engine is now in hand under army cognizance.

550 HP. Water-Cooled Engine.—For medium weight heavier-than-air craft. An engine of this type is in process of development in commercial hands. Tests are being conducted under Army cognizance and modifications are being recommended by the Army Air Service.

700 HP. "W" Type Water-Cooled Engine.—For heavier-than-air craft of large size. This type of engine is in process of development under Army cognizance.

1000 HP. "W" Type Water-Cooled Engine.—For aircraft of heavier-than-air type of extremely great size, now in process of design by the Army Air Service.

Engine to operate on heavy oil fuel, probably about 500 hp. The development of this engine is of mutual interest, in view of the existing fuel situation and in view of the desirability of eliminating, to as great an extent as possible, fire hazards existing in the use of present type aviation (airplane) engine fuels. The development of an engine of this type has been undertaken under Navy cognizance.

160 HP. 6-Cylinder Water-Cooled Engine.—This engine is being developed under army cognizance for installation in aircraft used in training. The development of this engine and of the engine noted under class (b) of approximately the same horsepower but of radically different type is being carried on with a view to determining which of the two types is the more suitable for this purpose.

300 HP. Cannon Engine.—This engine is being developed under army cognizance, for installation in an aircraft where it is desirable to have a gun firing directly ahead through the propeller hub.

350 HP. to 375 HP. Water-Cooled Engine.—For installation in pursuit airplanes. The engine contemplated is of the highest performance type, will be highly stressed, of very light weight, and probably of only moderate durability.

300-400 HP. 6-Cylinder Water-Cooled Engine.—Engines of this type are being developed under Navy cognizance for installation in rigid airships, or in large non-rigid airships.

Class (b)

Engines primarily of interest to the Army Air Service.

140 to 160 HP. Air-Cooled Engine.—This engine is being developed under Army cognizance for aircraft used in training.

Class (c)

Engines of primary interest to the Navy Air Service.

200 to 230 HP. Radial Air-Cooled Engine.—This engine is being developed under Navy cognizance as a step toward the development of a durable, relatively cheap engine for training purposes, or for small shipboard aircraft. Its development is desirable for training purposes, since greater powers are needed in aircraft for training than are required by the Army Air Service. Likewise, it is desirable to have available an engine of domestic manufacture of about this power corresponding with certain well-known engines of foreign manufacture, for use in small shipboard and other type aircraft.

250 to 275 HP. Engine.—This engine is to be developed for use in a twin-engined airplane or seaplane designed as a torpedo carrier, bomber, or spotting machine. For a twin-engined installation the total power of these engines is approximately equal to that of the 550 hp. engine noted under class (a), but the development of the smaller engine appears to be desirable from considerations of maneuverability and ease of installation in naval aircraft designed as torpedo carriers.

650 to 750 HP. Water-Cooled Engine.—The development of a larger type engine for rigid airships appears to be desirable, and at present it appears that 650 to 750 hp. represents the maximum power and weight that are practicable to concentrate in a single unit for this purpose. To be developed by the Navy Department.

Steam Engines.—The development of the steam engine is to be continued at once and worked to a definite conclusion as rapidly as possible.

Geared Engines.—The Navy is now engaged in the development of the geared engine for use in its aircraft. Detailed development of numerous types is extremely necessary at this time in order that the non-availability of engines of a given type may not prevent the development of types of aircraft of the greatest utility.

The importance and possible value of the development of an internal combustion engine of turbine type is being followed by the War and Navy Departments and there are some indications that increased progress in aeronautics will warrant its development in the near future.

The Tracking and Steering of Trailers Analyzed by a Graphic Method

Part II

Factors which affect the steering and tracking of various trailer outfits are further discussed and the graphic method of analysis is applied in concrete cases. Driver's skill in handling equipment is important.

By Marius C. Krarup

IN a comparison of the two systems from a mechanical viewpoint there would be room for other observations, but so far as tracking is concerned they can both be represented by the same diagram, with the understanding that in reality one or the other may be preferable according to the peculiarities and dimensions of the vehicle bodies, the roughness of service, the length of the coupling wanted, the preference for draft from frame to frame or from frame to axle.

The equivalence referred to does not merely permit simplification of diagrams. It also makes it clear that all tracking can be plotted as free trailing after a leading point—the hook or joint—so located in fixed relation to the leading vehicle (or pair of wheels, in the case of four-wheel steering) that it is moved to the outside of the curve to be described, the side opposite to that of the turn. By the use of automobile steering linkage the actual displacement of the leading point can be moderated, as when small overhang of the hook or joint is structurally desirable, and the desired tracking effect nevertheless obtained, but the plotting of the track can be done with a simplified diagram showing the equivalent theoretical displacement. The requirements for easy and rapid plotting of vehicle movements are thus reduced to: Simple diagrams of vehicles and a simple method for constructing any free-trailing curve. The latter is shown in Fig. 14.

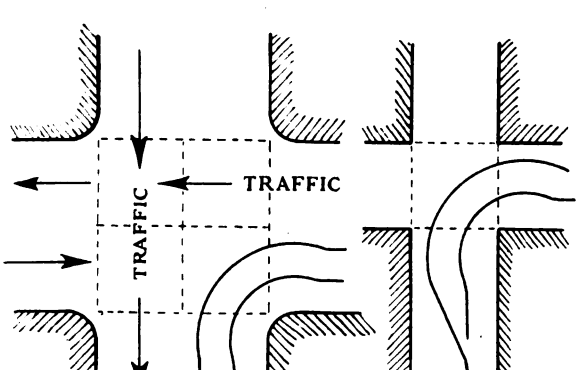

FIG. 11

There is shown a crossing of city street 60 feet wide and one of country roads 30 feet wide, and it is indicated why the steering requirements must normally be almost the same for both conditions. A wide turn and a close turn are traced in both cases. On the country road (or narrow city street) a trailer outfit must return to its side of the road after a wide turn, while on a wide street it does not leave its own side. The sharp turns are identical, except for the easement from rounded city corners

A comparison of city and country conditions, to both of which most trucks and trailers must conform, is illustrated in Fig. 11, with a view to establishing a working idea with regard to the shortness of turn that is required for operating comfortably in normal circumstances. Wider or sharper turns may be preferable at times, but for comparison of different systems for securing whatever degree of tracking is necessary it is obviously best to select a standard radius. Taking city streets to be 60 feet wide, with rounded corners, and the dependable roadbed in the country usually not over 30 feet wide, a turn in the city has only the advantage of the rounded corners over a turn on a country road, assuming that traffic rules normally restrict a turn to one of the four 30-foot squares of the street crossing, while in the country a hauling outfit can normally take the whole road for a turn. On this basis it may be said that the minimum demand to be made of a hauling outfit is ability to turn comfortably and without much reduction of straightaway speed from one 30-foot street or road to another, at whatever front and rear radius for the tractor unit may be found to be required for this purpose, and that preferably the outfit should be capable, with suitable speed reduction, of making such a turn on its own side of the road in the same manner as the truck of 13 feet wheelbase was seen to make it in Fig. 6, with a radius of 24 feet for rear wheels and 27¼ feet for the front wheels. To conform with the diagrams, radius is taken as the mean radius for the two wheels of a pair.

In Fig. 12 there is shown a turn made with a truck of 10 feet wheelbase drawing a trailer of 15 feet wheelbase, the distance from truck rear axle to trailer front axle being 10 feet and the hook about midway between the axles. The turn is made by a single steering gesture at the beginning and another at the end. The trailer steering may be either by axle steering or wheel steering, the location of the hook representing either form, as explained. The radius of the turn is made 30 feet for the rear wheels of the truck, and the figure shows that with this radius the outfit cannot quite turn the corner on its own side of the road of 30 feet width. The corner of the road is indicated in different locations to make the possibilities clear. One can always hug the side of one of the roads if the whole width of the other road is at disposal, but it is not possible to place the corner so that the incumbrance of both roads will be less than 16 to 17 feet. By forcing the tracking of the rear trailer

wheels it may be done, however, even with a turning radius of 30 feet, since the figure shows the hook leading the trailer on a circle slightly larger than the circle of the rear wheels, and the front of the trailer tracking almost exactly with the latter. Nothing but the rear trailer wheels prevent hugging the side of the road more closely.

For comparison the same outfit is shown in Fig. 13 with longer overhang of the hook to track more closely, and making the turn with a radius of 20 feet for the rear truck wheels. And it is here observed that the trailer in this case snakes perceptibly, while in the first instance it was turned only very little to the left at the beginning of the right turn.

It is also noticed that the long trailer wheelbase makes trouble. The trailer body drags into the curve of 20 feet radius worse than into that of 30. The front trailer wheels are turned at an angle that cannot be realized unless the wheels will turn under the vehicle. More diagrams than it is practicable to print here would be needed to demonstrate definite conclusions from these observations and others which Figs. 12 and 13 may suggest. It is useful to remember, however, with regard to all the diagrams that they express a relativity only and are applicable with a change of scale. Figs. 12 and 13, for example, are applicable to shorter vehicles turning with shorter radius on narrower roads.

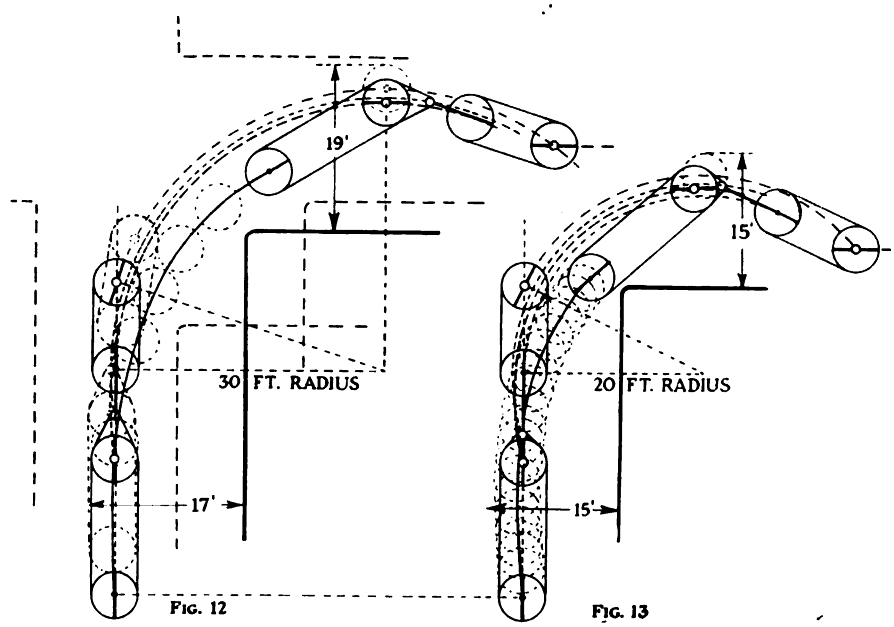

FIG. 12 FIG. 13

Turns made with a trailer outfit on a 30-foot road with turning radius of respectively 30 and 20 feet. The outfit is in both cases a truck of 10 feet wheelbase drawing a four-wheel trailer of 15 feet wheelbase, but the overhang of the coupling hook is made longer in the second instance to produce closer tracking. The length of the trailer wheelbase operates to the contrary, however. Snaking effects appear plainly in the diagram of the sharper turn. By considering the corner of the road for different locations, as indicated in broken lines on Fig. 12, an idea can be formed of the best place to begin a turn for different conditions of traffic, or when the question is of turning from one road to another of different width, the expedient of moving the corner on paper being applicable to any diagram drawn. Some trailers of 15 feet wheelbase will not be able to make the sharp turn in Fig. 13, because their front wheels cannot be turned to an angle as large as that here required

The matter of greatest interest in the whole subject lies perhaps at present in devising a method by means of which trailer curves can be readily shown on paper for any kind or dimension of outfit and with reference to any width of road that may be of interest. If applicable to the curves produced by backing and maneuvering, it seems evident that such a method can be turned to good account for familiarizing drivers with the results obtained in maneuvering by various steering gestures, since a considerable number of frequently occurring situations could be diagrammed and studied. The fundamental principle for such a method is indicated in Fig. 14, which shows a leading point, A, describing a curve and the curves described by three trailing points, B, C and D, starting from different relations to A, and the manner in which the three trailing curves are constructed. In Figs. 12 and 13 the truck front wheels make a leading point in relation to the truck rear wheels and the hook, the hook a leading point in relation to the trailer front wheels, and the latter a leading point in relation to the trailer rear wheels, but the construction is simplified for a simple and sustained circular turn with a known center and no change of radius. The curve of the leading point in Fig. 14 may be composite and of any degree, and the points, 1 to 14, selected for determination of corresponding points on the trailer curves, need not be equidistant. The data for construction are two, (1) that the trailing point is a given distance from the leading point, and (2) that the trailing point wheel follows a curve to which it can be at every point tangential. From each of the points on the leading curve there is, therefore, described a circle with the distance to the trailing point as radius, and, beginning with the original position of the trailer point, the shortest course from one point on the trailer curve to the next one is determined by a tangential arc from the already determined point on the trailer curve to the distance circle for the next one. In practice it is more satisfactory to make the arc intersect the distance circle at two points close together and draw the trailer curve midway between the two points of intersection. A straight line from any given point on the leading curve to the corresponding point on the trailer curve will be found tangential to the latter in all cases, but these lines are not shown here.

The construction approximates geometric accuracy in the measure as the spaces on the leading curve are reduced in length by increasing the number of construction points. If not enough are used, the trailer curve slips inwardly a little, but slip of very similar nature occurs in reality on the roads, because the drag, due to traction resistance, tends to flatten every curve a little, especially where the turns are sharp.

In this diagram the leading point, A, may be taken as representing the front truck or trailer wheels in relation to B as the rear wheels, but the initial relation of A to C, and particularly to D, is such as will occur mostly with semi-trailer outfits, in which case A can be taken as the fifth-wheel joint. The application to two-wheel trailers, dollies and trailers with fifth-wheel or axle steering is equally obvious, and it is noticed that curve D represents a backing movement followed by a go-ahead.

To see whether the method is fully applicable to backing movements of four-wheel trailer outfits, one must take cognizance of the practice so far followed, consisting in locking the front wheels when the outfit is to be backed up while unlocking the rear wheels and steering them by hand. The steering by hand should only consist in preventing the wheels from whirling around to their most extreme position and thereby blocking further rear-

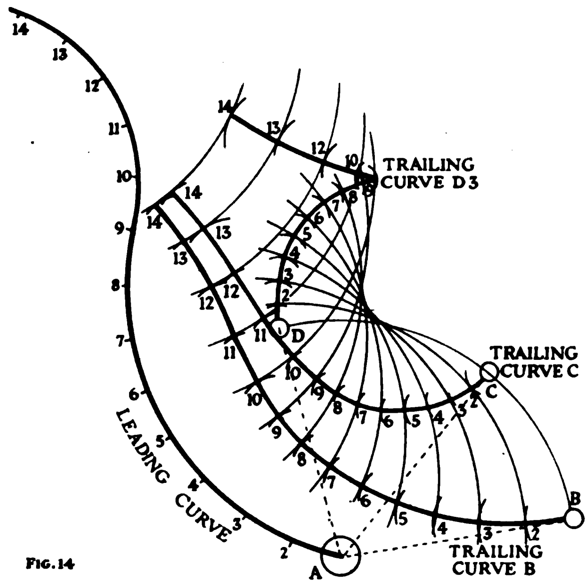

FIG. 14

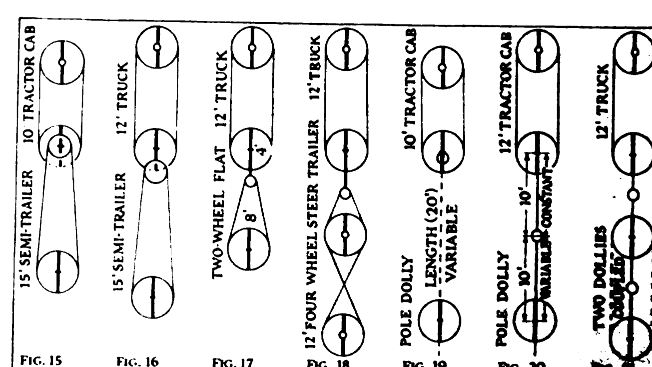
Fig. 14—Diagram showing how the tracks of trailing wheels can be easily plotted, when the curve described by leading wheels or by a relatively fixed point, such as a coupling hook, is known or assumed. By this method and symbolic figures for the vehicles (the figures drawn to scale) all movements in turns and maneuvers of semi-trailer and trailer outfits, as well as of trucks, can be put on paper and be made to serve the needs of drivers, designers, owners of transportation outfits and others interested. For explanation see text

ward movement of the outfit. On this assumption, the curve of the rear trailer wheels can be laid out in a diagram as a trailer curve determined by the curve described by the fixed front wheels. In practice some deviation from this course can be effected by forcing the unlocked rear wheels to a path not quite consistent with the path of the hook which pushes the locked front wheels, but some skewing, skidding and strains are involved which can scarcely be considered desirable. On the other hand, some drivers have acquired the knack of performing the simpler backing-up movements with a four-wheel trailer outfit without first reversing the functions of the trailer wheels. By holding the angle between truck and trailer drawbar down to a maximum of, say, ten degrees, they manage to push the trailer back, if the road is good enough, without having the push take effect first in turning the steering wheels of the trailer around to their limit. Possibly the locking and unlocking method is not the final one, since it interferes with one-man operation, and possibly the driver's method can be systematized and developed on safe lines.

For the present the regular method remains of superior practical interest, and, as it can be plotted with reference to the most frequently demanded maneuvers, it probably should be so plotted in order to help drivers to perceive quickly, in every arising case, how and how early the jockeying for place should begin if a certain desired position of the outfit is to be reached expeditiously and without alternation of backward and forward movements. The whole subject of backing and maneuvering with trailer and semi-trailer outfits could perhaps be covered sufficiently for the needs of drivers' training schools in a hundred diagrams, but is too large to be taken up here, although its relation to questions of steering and tracking is evident. Contractors and others having work on hand demanding maneuvering with transportation outfits day after day in the same places and in the same manner might find it advantageous to plot such maneuvering in advance for the particular outfits to be used. Such a development would only be one among several which have accompanied the general introduction of haulage by motor power.

Even in the simpler matters of turns and turnouts on the road, the driver's share in making his equipment work satisfactorily is conspicuous. Figs. 7 and 8, as well as Figs. 12 and 13, reveal some of the points to be observed. The free-trailing outfit may be turned with some abruptness and without much reduction of speed if the leading vehicle is turned widely some distance before it is seemingly necessary. The closely tracking outfit, on the other hand, may turn much less out of its course, but should either reduce speed considerably—assuming that it has been run fairly fast on the straight stretch, where all tracking gear is dormant and harmless—or follow the gentlest possible transitions from one curve to another. As if to compensate, these transitions always can be gentler than with free trailing, since the turnouts of the leading vehicle can be smaller. And it is the driver's business to take this advantage to gain time and avoid snaking, with its irregular and alternating lateral strains and jolting. The lengths of the wheelbases and of the couplings influence the driving results so much, however, that very little can be said in terms of generality without a likelihood of errors or erroneous impressions. No sharp line of demarcation separates the free-trailing outfit from the forced-tracking outfit. Excepting only the truck alone and the tractor cab with semi-trailer, which are pure free-trailers, all outfits have couplings which force the next pair of wheels more or less and couplings which don't. And the results are a blend more or less happily conceived. The driver requires practice with each type of outfit and with different dimensions of units, and the only available auxiliary and part substitute for such practice would seem to be the study of diagrams, under suitable direction, the diagrams being preferably on a large scale with specified dimensions and distances, but with all superfluities of construction omitted. Perhaps it could be taken for granted that a somewhat general



Figs. 15 to 21—Symbolic figures adapted for use in plotting curves for the hauling outfits which they represent. In Fig. 16 the small overhang shown for the fifth-wheel coupling should be changed if the investigator has a different position of the coupling in mind. All other dimensions are similarly subject to change. Fig. 18 and Fig. 21 produce very similar curves, with the same dimensions for vehicles and couplings, the only material difference being that the wheelbase in Fig. 18 is constant, while that in Fig. 21 fluctuates slightly, getting shorter at sharp turns, with the rear bolster sliding as well as swivelling in its base. The positions of bolsters in the dollies is not indicated, as it does not influence the tracking, but in Fig. 19 the pintle hook is supposed to be so nearly in line with the front bolster that no provision need be made against longitudinal shifting of the load, or, if the load is lashed, the hook coupling may be slidable or the pole may be omitted, as suggested by showing it in a broken line

use of such diagrams would react favorably upon design and disposals.

All the trailer types and combinations diagrammed in Figs. 15 to 21 should now perhaps be shown turning a corner with a 24-foot radius for the driving wheels, also describing the composite curves required for turning off a straight course and back again, and possibly even for completeness in backing and maneuvers. The reader, however, can do this on a larger scale and for the specific dimensions which interest him most, and so nothing is done here but to present the symbolic figures which, it seems to the writer, can be suitably used for the work.

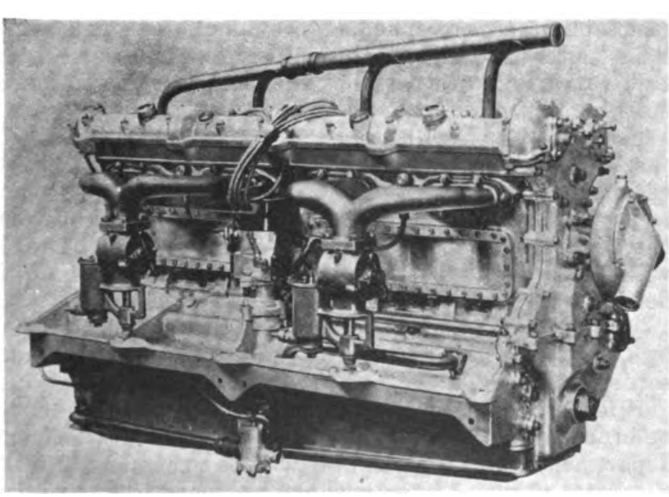
Ruts in the road can, of course, be troublesome for trailer outfits on account of the length of these in comparison with the length of those vehicles by which the ruts were formed, the difference naturally resulting in curves for the ruts conflicting more or less with those which trailer wheels should follow, and it is not evident that free-trailing wheels are always better off in this respect than wheels which track after those in front of them. There is likely to be some skewing and dragging. A yielding element is provided in automobile steering linkage in the buffer springs in the joints, and these may help somewhat. The worst case, on the other hand, seems to be where two pairs of wheels, not very far apart, are steered to opposite sides, as in vehicles with four-wheel steering. The matter, while perhaps of minor importance, suggests at all events that the introduction of a suitable yielding element in the steering mechanism may become one of the requirements of the future, if trailer outfits are to ply largely on common roads, on a par with trucks in many classes of work. The remedy now must lie mainly with the driver and in the form of preventing the wheels from dropping into ruts wherever it is not clear how they can be taken out again.

The application of brakes to trailers in downhill driving is another matter connected with the subject and on which some development must be expected in order to make four-wheel trailers compete effectively with semi-trailers outside of the limited field where four-wheel trailers now show superior economy. The types represented in Figs. 18, 20 and 21, which are close trackers under pull, plot less determinate curves when they go from pull to push, as in downhill driving and backing-up movements, though the jointed and slidable pole for the dolly, in Fig. 20, is doubtless stiffened considerably by the load lashed to the swiveling bolsters. These are matters for consideration in the evolution of trailer service, but the writer is only suggesting a method for investigating them. As said at the outset, the subject also has a military angle and another one, both military and civil, relating to the use of caterpillar tractors —with some sidestepping ability not shared by other tractors—with either trailers or semi-trailers.

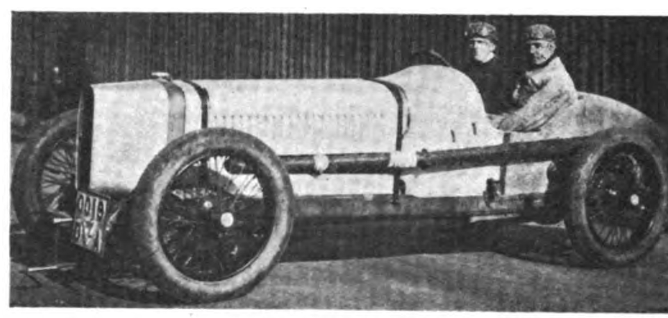
The Sunbeam Car for Indianapolis Race

ACCOMPANYING illustrations show the engine and complete car which the Sunbeam Co., Wolverhampton, England, has entered in the Indianapolis race to be held on Memorial Day. It is, with a few variations, a replica of the three cars entered for the French Grand Prix. The eight cylinders in line have a bore and stroke of 65 x 112 m.m. (2.56 x 4.41 in.), giving a total cubic capacity of 2957 c.c. There are four valves per cylinder, operated by two overhead camshafts, each driven by a train of gearing at the front end, where also the water pump receives its drive direct from one of the intermediate pinions.

Originally four carburetors were fitted, but better results have since been obtained with two Claudels with branched manifolds belled out at the flanges of the ports of each pair of cylinders. The compression ratio is 5.7 to 1. Delco ignition is used.



The Sunbeam 3 litre racing engine has 8 cylinders in line, and uses four valves per cylinder. The latter are operated by two overhead camshafts



The Sunbeam car entered in the Indianapolis Memorial Day Race

On the Grand Prix cars a four-wheel braking system is used, but on the Indianapolis car the rear wheels only are braked. The latter car is also peculiar in having the chassis as a whole mounted out of center in relation to the wheels, being closer to the left than to the right to assist cornering, which of course occurs in one direction only on the track.

The final gear ratio on top has not been decided upon at the moment of writing, but it is claimed that 130 b.hp. has been developed by the engine and that 100 m.p.h. has been attained at Brooklands track on the third speed of the four ratio transmission.

VOLUME 1 of the Technical Report of the Advisory Committee for Aeronautics (Great Britain) for the year 1917-18, has recently made its appearance. It covers general questions, airships and general airplane research, and is a collection of reports issued separately during the war. A second volume will deal with propellers and full scale work on air planes and a third on strength of construction. These volumes constitute a record of the aircraft research done in England during the war.

Idleness and Its Relation to Industry

This paper takes up the question of industrial idleness in its various phases and discusses it chiefly from the cost accounting standpoint. It contains, however, a remarkably clear analysis of the entire problem which will interest executives of every kind. Here is a pioneer effort in this field.

By T. W. Dinlocker and A. W. Wainright*

IDLENESS is to the industry as disease is to the body. It does not depend upon recognition for its existence. In fact, the less it is recognized the more likelihood it has of thriving and spreading. Like disease, it must be treated or the body suffers. A diagnosis must be made to determine the extent of idleness before remedies are applied. It is the purpose of this paper to discuss the philosophy and classifications of idleness and to point out their source and effect on industry and suggest methods of reflecting the expense of idleness in such a manner as to bring it under control.

Idleness within the limitations of this paper may be defined as to the expense in connection with idle facilities of any nature whatsoever. The methods for securing this control will be discussed under the following subjects:

I. Classes of idleness,
II. Terminology—Cause and Control,
III. Recording and Report,
IV. Philosophy and Application,
V. Accounting for Cost of Idleness.

The sources of idleness are usually found in management, men and outside influences. These sources may be due to either normal or abnormal conditions, which may be controllable or uncontrollable. These conditions fall into many divisions, which are usually reflected in idle facilities.

Classes of normal or controllable idleness are as follows:

Management

1. Excess facilities
2. Unequalized facilities
3. Obsolete facilities
4. Shortage of raw materials
5. Absence or lateness of men
6. Men waiting

Men

(a) for work or material
(b) for instructions
(c) for set up
(d) for helper
(e) for power
(f) for crane
(g) for repairs
(h) for tools
(i) for miscellaneous

7. Men absent for welfare activities.

Classes of abnormal or uncontrollable idleness are as follows:

Outside influence

8. **Business depression**
9. **Strikes**
10. Labor shortage
11. Material shortage

*Mr. Dinlocker is assistant comptroller, S. K. F. Industries, and Mr. Wainright is works auditor, Skayef Ball Bearing Co. The paper was presented before a recent meeting of the New York section of the Industrial Cost Association.

In the last analysis the management should determine what constitutes idleness, and the following discussion on terminology is offered in the hope that it will be of some assistance in reaching this decision.

Excess Facilities: To meet possible demands of customers for immediate delivery one of two conditions must exist: The stockroom must either be well filled with finished product ready for shipment and finished parts ready for assembly, or else there should be sufficient facilities in excess of the amount required for normal sales to produce without delay the increase in demand.

It is a question whether or not the manufacturers are willing to invest in excess facilities or prefer to keep a surplus stock of finished product on hand. The uncertainty, no doubt, is caused by the necessity of providing additional capital in either case and the resulting increase in carrying charges.

Without attempting to determine which of these methods the management should follow, we shall assume, for the purposes of this paper, that the method of providing excess facilities has been followed. If the excess equipment is evenly equalized throughout the producing departments, it is logical to assume that idleness will occur when the demand returns to normal.

The question of whether or not interest should form a part of cost is a subject which, for the sake of brevity, it is not proposed to treat in this paper.

When companies are established it frequently happens that additional land and floor space is provided which is in excess of immediate requirements. This is usually done for the purpose of allowing for the expected expansion of the business. In enumerating the various divisions of excess facilities, items in the nature of unused real estate and floor space might be included. It is sometimes necessary, also, to install excess facilities to provide for breakdown or some unexpected interruption in machine capacity.

Unequalized Facilities: Facilities become idle in cases where a regular flow of production is not possible because all the departments have not been synchronized to produce flow of work. It happens in some cases that one department is over-equipped and is in need of work, while another department is under-equipped and is flooded with work.

This class of idleness is usually a dead manufacturing loss, although these facilities might be utilized under several methods.

FIRST: Production in the lagging departments should be brought up to an even capacity with the most efficient departments, and to do this it will be necessary to make a careful survey of the product by operations, together with a study of machine capacities.

SECOND: Where the efficiency in all departments is

brought up to its highest point and it is found that a regular flow of production is not prevented by inefficiency in some departments, it is logical to assume that this condition is caused by unequalized facilities. A decision should then be made as to whether the excess facilities should be disposed of or whether additional facilities should be purchased in the lagging departments.

Before purchasing additional facilities a study of the market for the product should be made. Limited markets often make it exceedingly dangerous to counteract unequalized facilities by equalizing and throwing more production upon the sales department. To expand the production to a point over the maximum that could be expected in the particular trade would be violating the theory of demand and supply. In cases where the market is practically unlimited the point should be borne in mind that the securing of additional facilities would not only increase sales, but would also place into active operation facilities that are at present idle.

THIRD: To run overtime work in the lagging departments for a sufficient length of time to bring up the departments' output to the capacity of the departments in need of more work.

Obsolete Facilities: It is possible for facilities that have become obsolete to be permitted to remain standing in the plant. Unless they were put to work they would be reported idle and would consequently incur a certain amount of cost of idleness that is not offset by production. Whereas, if they were replaced by active facilities, production would increase and the cost of idleness would disappear, resulting in decreased cost.

Shortage of Raw Materials: Idle facilities may be caused by failure to receive raw materials when needed, which may be due to errors—either clerical or of judgment in planning and purchasing—which results in delay in shipping on the part of the vendor or uselessness when received at the plant.

Shortage of raw materials due to causes other than those above mentioned would probably fall into the classification of abnormal idleness and will be discussed under that heading.

Absence or Lateness of Men: Facilities become idle through absence or lateness of men. This might or might not be serious, depending upon the particular circumstances of the case. Some of the factors causing this idleness may be enumerated as follows:

(a) Personal or family illness
(b) Transportation delays
(c) Weather conditions

There is another class of idleness, known as waiting time, which arises in the case where operators are present and are prevented from functioning for various causes, usually involuntary on their part. Waiting time, then, in our meaning may be defined as all time spent by productive workers in idleness for any reason whatsoever. Waiting time may be classified under many headings. In general, however, it is thought that the most important headings may be referred to and defined as follows:

Waiting for Work or Materials: Under this classification the operator may be idle due to:

Faulty arrangement of facilities,
Imperfect planning which results in poor routing and trucking of work,
Improper stockkeeping methods causing delays in the arrival of material at the production centers.

Waiting for Instructions: Under this heading reference is made to idleness that develops in cases where workmen have carried their work as far as they can go and are waiting for specific instructions, such as:

Instructions lacking or missing,
Defective or incomplete,
Absence of blueprint,
Absence of service card.

Waiting for Set-Up: Under this heading reference is made to idleness upon the part of workmen in cases where jobs are changed and it is necessary to readjust the facilities to new specifications.

Waiting for Helper: Idleness is caused in cases where it is impossible for a workman to proceed with the job in hand until he secures the services of a helper. This delay might be caused through the improper control of the workmen available.

Waiting for Power: Idleness is caused through lack of power, which may be due to internal or external causes.

Waiting for Crane: In some industries, where the product worked on is difficult to handle because of bulkiness and weight, it necessitates the use of cranes and other hoisting apparatus. In cases where these are not temporarily available idleness results.

Waiting for Repairs: Idleness results from facilities which are in the course of repair, some of the cases of which are as follows:

Dilatory maintenance,
Insufficient repair men,
Careless and inefficient workmen,
Lack of instructions to workmen,
Defective facilities,
Where the unit in a group is being repaired and another unit is idle,
Lack of material with which to do repair work.

Waiting for Tools: In cases where it is necessary to use machine tools or tools for bench work, idleness is often caused by improper planning regarding the manufacture of the tools or by unsuitable design which could only be discovered after the tools were put into operation. Other causes are an insufficient quantity, tools in the course of repair and tools lost through negligence.

Waiting for Miscellaneous: It is customary to provide miscellaneous accounts to take care of items not applicable to subjects outlined and to provide a catch-all. It is sometimes the case that miscellaneous items deserve much consideration. This particularly refers to the idle facilities and to the apparent detail of the methods used in having workmen report their time.

An example might be based upon a factory of 100 working on a 10-hour day at an average wage of 30 cents an hour. It is also assumed that the workmen change jobs at an average of five times a day, taking approximately five minutes in the task of having their time reported closed on one job and started on another. The time lost for each day for each employee would be 25 minutes. This would represent 2500 minutes for the entire plant and, calculated at the average of 30 cents an hour, would result in a daily expense of $12.50. This expense, carried on at this rate for an average working year of 300 days, would total $3,750.

Modern timekeeping appliances permit the workmen recording their time without leaving their machines, and some planning systems are based on methods whereby truckers move jobs to and from workmen's benches and inspection cribs, having the time elapsed recorded by time clerks centrally located.

Another instance of miscellaneous idleness would be where workmen are allowed time off to wash up and ring out. A calculation of the expense of this nature can be made on the same basis as that cited above. It was not so much the intention of the writers to indicate

that a few minutes idleness of this nature would have a large effect upon increasing the expense of idle facilities. Very probably it would be impossible to make allowances in these cases and would be included in the time used, in which case no idleness would be reflected.

Another argument that might be advanced against the recording of such miscellaneous idleness might be that of the detail necessary in recording such small periods of elapsed time. However, inconvenience should not be the deciding factor in anything that is necessary and would prove of constructive value. There would be no rebuttal to this argument if the records were not utilized to prevent this indirect class of idleness. If the mere reporting of this information were but to call to our attention an occurrence which had heretofore remained undiscovered, it is felt that any expense incidental to gathering this information has well been capitalized in the subsequent correction of such leaks.

Men Absent for Welfare Activities: It is the custom in some establishments to conduct activities incidental to the welfare of the employees. Meetings of shop committees, athletic and beneficial associations would be examples. During the world war it was customary to conduct Liberty Loan rallies, and it is yet the custom to permit speakers to address employees, these affairs being held during working hours and on the company's time.

Business Depressions: Many reasons have been advanced as causes of our financial panics and business depressions, some of them the result of much study and thought. It is generally conceded that the most important factor is traceable to over-speculation and a consequent over-extension of credit. It is a noteworthy fact that business depressions have occurred in the past at approximately regular intervals, and, while history need not necessarily repeat itself, it is felt that idleness will always be caused by this factor. Industry receives its first tangible notice of depression in the form of cancelled orders, deferred shipments and a shrinkage in new orders received, resulting in curtailed production. While idleness resulting from depression cannot be directly controlled, its effect may be modified by operating the facilities that would ordinarily remain idle. Should it be determined to continue production, such decision would probably be based on reasons similar to the following:

FIRST: The willingness of the market to absorb product at manufacturing cost, thus eliminating the expense of idle facilities.

SECOND: Forcing sales at prices that will only return prime cost, ignoring burden consisting of fixed charges. The object contemplated by this method is the maintenance of the manufacturing organization, rather than the elimination of the expense of idle facilities, which would exist whether or not this procedure was adopted.

THIRD: Building up inventories by utilizing the facilities which would otherwise be idle for the purpose of being in a strategic position at the resumption of normal sales conditions. Production at such times would increase inventories which probably would not be readily disposed of if the depression was of protracted length. In such cases the ability to negotiate loans and to carry the resulting charges would be an important factor.

Strikes: Strikes may be defined as a form of manufacturing paralysis. It is usually temporary, and may be serious or trivial. During strikes labor and management may be said to be out of alignment. Most strikes are, in the last analysis, based on wage questions.

Strikes may be traced to many causes. As a general statement, however, it is thought that the following causes are fairly representative:

1. Unfair hours and wages,
2. Loose employment methods of hiring and discharging
3. Improper methods of work.
4. Poorly qualified foremen.
5. Improper inter-relation of workers,
6. Lack of provision for safety and health,
7. Antagonism of labor organizations,
8. Agitation by radical influences,
9. Sympathetic strikes.

Since the strikes are more or less controllable, it is felt that the following policies would do much to reduce the hazard of idleness from this cause:

1. Sound wage plans,
2. Encouragement of employees,
3. Provision for advancement,
4. Mutual understanding.

Labor Shortage: Idleness is found in cases where local labor conditions are such that sufficient labor cannot be secured to operate the full capacity.

Material Shortage: Idleness under this heading is presumed to mean idleness resulting from delay in receiving material caused by forces outside, such as:

1. Inability of vendor to meet contract.
2. Transportation strikes.
3. Transportation embargoes.
4. Shipments lost in transit.

Recording and Report

In order that the management may be in a position to realize the significance of idle facilities, after which they may consider reasons and remedies, it is first necessary to provide practical methods of recording upon which proper reports or graphs may be based.

The recording of idleness will necessarily entail some detail work and consequent expense. It is usually customary in the industrial world to greet a statement such as this as being closely related to "red tape." It is assumed that management is always desirous of ascertaining factors causing loss.

Records are either useful or useless. To be useful a record must produce results, by which is meant pointing the way to increased profits. Records are inanimate and cannot of themselves produce profit. The best they can do, and all that may be expected of them, is a true reflection of conditions. Resulting action depends upon the management.

Recording of idleness may be accomplished through clerical or mechanical means. It is not advocated that workmen report idle time, as it necessitates temporary interference with his work and retards production.

In recording idleness the vital factor is the cause and mechanical means do not easily accomplish this result. Another objection attached to the use of mechanical means of recording is the expense incidental to the installation of equipment necessary. In view of the fact that all productive work is not machine work, and that all machine work cannot be automatically recorded, it is recommended that the recording of idleness be accomplished by clerical means.

In most establishments some method has already been devised for recording labor activities. It is suggested that the recording of idleness be assigned to the same authority. In order for them to properly record idleness they should be acquainted with the various classifications of idleness and the causes as enumerated above.

A form should be provided for reporting idleness and should contain what the management requires for forming an intelligent decision. In addition to such informa-

tion, it is thought that the following information must be included on the form:

Date
Facility number and name,
Duration of idleness,
Cause.

Idleness is the difference between possible or standard hours and used hours, which should be supported in detail on the above forms.

By possible or standard hours is meant the hours the facilities would be normally expected to operate. In computing possible hours, Sundays, Saturday afternoons and holidays would be omitted. For instance, in an establishment operating a ten-hour day in a month in which there are 22½ working days the total possible hours would be 225 hours.

Having recorded the total amount of idleness in its various classes, the matter of preparing reports will now be briefly discussed. As idleness is either normal or abnormal, it seems advisable to prepare the report in such a manner that would reflect the total applicable to each class, analyzed into its subdivisions.

A report prepared along the lines of the attached form would seem to provide information enabling the management to realize the extent and seriousness of idleness in his plant and would aid him in surmounting his difficulties.

Philosophy and Application

In an earlier part of this paper idleness was divided into normal and abnormal classifications in order to explain what was meant by idleness that was controllable and that which was uncontrollable. Controllable idleness is governed by the manufacturing organization, while uncontrollable idleness may be traced to shortcomings on the part of the general or sales departments of the company. On the other hand, some items of uncontrollable idleness are caused by factors entirely beyond the regulation of any department.

If no distinction were made between these two classes the expense attached to each would probably be absorbed in manufacturing costs. The opportunity is taken at this time to point out that it might be profitable, from the standpoint of management, to charge manufacturing costs with the expense incident to controllable idleness and to relieve manufacturing costs for the expenses incident to uncontrollable idleness.

The reason both classes of expense have heretofore been considered as a proper charge to manufacturing cost may be found in the thought that accountants have not fully appreciated the problems of manufacturing and the viewpoint of the operating officials.

For this reason it has been the common conception of many manufacturers to feel that the average or unit cost increased as the volume of output decreases. This conception is technically correct, but there are many objections to absorbing into manufacturing costs the entire burden when the diminished output is caused by business depression. Fixed charges, such as depreciation, taxes, rent, insurance and administration, are items of expense which accrue regardless of idleness or activity. To reflect the general effect of fixed charges upon volume of output we shall assume a case where a manufacturer has two plants making the same product. We shall further assume that plant No. 1 is idle, while plant No. 2 operates at full capacity. Other things being equal, manufacturing costs at plant No. 2 would be normal. The fixed charges of plant No. 1 would continue and might entirely eliminate the profits of the business as a whole, but the cost of manufacturing the product would not have been increased by the fixed charges of plant No. 1.

On the other hand, we may consider these two plants as two departments under the same roof; that is, plant No. 1 now becomes department No. 1 and plant No. 2 becomes department No. 2, both component units of a single organization; department No. 1 is still idle and department No. 2 is operating to capacity. Working under the common conception, the overhead would not be relieved for the expense of idle facilities, and the fixed charges of the idle department would be absorbed in the output. The result would be that the cost of manufacture in department No. 2, which includes the cost of idle facilities in department No. 1, would be higher than the cost in plant No. 2, where all the facilities were busy. This would be true, although all the facts are identically the same, with the exception of the treatment of fixed charges. This condition would be aggravated in the case of a manufacturer whose output was of a varied nature.

Whether or not the expense of idle facilities constitutes a part of manufacturing cost or should be treated elsewhere in the accounts is a basis upon which difference of opinion may form. However, the writers are of the opinion that the expense of idle facilities is not entirely a proper part of manufacturing cost, and, in support of this contention, offer the following reasons:

1. **General:** While true costs are needed at all times, they are especially helpful during periods of depressions when business requires careful administration. Absorbing expense of idleness in manufacturing results in widely fluctuating costs, and consequently the management is without the aid of the cost records in determining comprehensive manufacturing and selling policies.

2. **Effect on Manufacturing Management:** To include the expense of idleness in costs would prevent the use of cost records for purposes of comparing present performance with those of periods in which idleness did not exist. For instance, the output per unit might be higher, but the increased cost might indicate that the output per unit was lower.

3. **Effect on Financial Management:** In cases where the product is shipped as soon as manufactured, no difference in the net profit is shown, whether the expense of idle facilities is absorbed in manufacturing costs or treated elsewhere in the accounts. On the other hand, if the product is not promptly shipped and the tendency is to increase inventories, it will be found that undue inflation of inventories and profits follow. In later periods, when the product commences to move, profits appear to be much less on account of the inflation in cost. This is due to the fact that the profit had actually been anticipated at the end of the previous year through the inclusion in inventories of idle facilities' burden.

4. **Effect on Sales Management:** When selling prices are based on cost, the inclusion of idle facilities' burden would force selling prices so high as to prevent the securing of new business when the establishment needs it most.

Sales policies may be outlined in a more definite manner if the expense of idle facilities were known as a separate factor. The mere transferring of idle facilities' expense from manufacturing cost does not abolish it, and as such it must be borne in mind when outlining sales policies and prices. Knowing the extent of the expense of idle facilities as a separate factor would enable the management to determine the following:

(a) The amount necessary to increase normal selling prices to provide more profit to be used as an offset to idle facilities' expense.

(b) When competitive or other conditions prevent increase in price the volume of sales necessary to increase volume of production consequently eliminating idle facilities' expense.

Whether or not the expense of abnormal idleness is to be absorbed into cost or charges elsewhere is a matter for the management to decide. In this discussion it has been the endeavor to show some of the points upon which this decision might be based. In any event, it is suggested that provision should be made for collecting the expense of such idleness as a separate element of costs.

For the most part normal idleness should be included in manufacturing cost, because it is felt that such idleness is controllable by management. Such idleness covers many items, but it is thought that the list mentioned under normal idleness is fairly complete. It is not reasonable to expect that there can be secured 100 per cent of possible operating time and, therefore, it constitutes a constant proper item of cost. Having determined to include it in cost, proper control may be maintained by collecting it as a separate account in the overhead. Where questions arise as to the amount of such expense that has been absorbed into cost, the treatment above prescribed will prevent any shifting of responsibility.

It is difficult in some cases to determine normal idleness chargeable to cost, as idleness due to excess facilities might have been caused by both manufacturing and financial policies. Excess facilities that are a protection to production in case of breakdown would be an instance of manufacturing policy. Excess facilities, such as land and buildings originally purchased with investment or expansion possibilities in mind, would be an instance of financial policy. It is suggested that a reasonable effort be made to distinguish between these two classifications of expense and appropriate reflections made in the accounts.

Accounting for Cost of Idleness

Having discussed the various arguments in favor of including in costs the normal expense of idle facilities and excluding from costs the abnormal expense of idle facilities, several methods of computing and applying the expense in the accounts will be reviewed.

The particular method of overhead distribution in operation at any establishment need not necessarily be discarded to install a basis for idle facilities' relief. However, burden distribution methods might have to be adjusted in order to accomplish the object desired; namely, that of having our costs represent the results of normal activities without the influence of abnormal factors of uncertain character and length.

It is not the purpose of this paper to enter into a technical discussion of cost accounting, but it is thought best to insert here a short discussion on the method of relief to manufacturing cost, the theory of which will hold, except as to detail, in most cases where idle facilities exist.

In view of the wide use of the "percentage of overhead to productive labor" basis of distributing overhead, we shall assume that the manufacturer uses this method. We shall assume, also, that his plant is divided into many departments, the facility in each department being approximately the same, and that the system in vogue provides for securing total expenses by departments. Referring to the example previously quoted, regarding two departments shut down and the other in full operation, it is obvious that the idleness in each department must be computed separately if the process or departmental costs are to be accurately relieved. This information could be secured from a report similar to the one annexed to this paper, and the ratio of abnormal idle hours to possible hours determined.

It would first seem that this ratio should now be applied to the total departmental portion of burden, which includes all fixed charges, and relief made for crediting work in process account, and charging some general account outside of manufacturing. Before doing this, however, it is necessary to consider those expenses other than fixed charges, such as salaries and wages of factory administration, accruals to such reserve accounts as reserve for repairs, reserve for inventories, and other accounts not directly related to volume of output. There is usually a point below which a manufacturer cannot reduce organization and expense, while sales and output may continue to decrease far below this point.

Before applying relief it is, therefore, suggested that a statement of overhead be prepared to be known as "overhead eligible for idle facility relief." This is done by simply reviewing each account in the manufacturing card of accounts to determine its eligibility as part of the idle facilities' relief and listing on a columnar analysis sheet the accounts vertically on the left-hand side and the departments horizontally across the top.

As overhead is finally applied to product on the percentage of overhead to productive labor in each department, it is, of course, necessary to transfer the overhead of the non-production departments to that of the production departments before this ratio can be secured. This is also necessary in preparing the statement of "overhead eligible for idle facility relief." Therefore, each production department will absorb that portion of the non-production departments' total overhead as their productive labor is in proportion to total productive labor.

We now have before us the total for each department of those expenses which accrue regardless of volume of output. It is now only necessary to departmentally apply the "ratio of abnormal hours to possible hours" to totals of eligible overhead to secure the expense of idle facilities not chargeable to manufacturing.

The amount of this relief would be credited to each productive department and the total charged to profit and loss surplus, or reserves provided for idle facilities or contingencies.

By this method the expense of normal idleness controllable by the manufacturing management is indirectly absorbed into costs. It is felt, however, that it is necessary to collect this expense in one account, the caption for which might be "manufacturing expense of idle facilities," for the purpose of establishing a means of bringing this expense forcibly to the attention of the management. This is accomplished by crediting the various overhead accounts making up "eligible overhead" and charging, per contra, the "manufacturing expense of idle facilities account."

This account would also include the cost of all waiting time of the workers, consisting of wages paid to men waiting for tools, repair or other causes heretofore enumerated. The total of this account would represent a part of the general overhead distributed to the cost of the product.

In those plants that maintain service departments, such as millwright, tool room, electrical, carpenter, etc., all that has been said of idle facilities applies here with equal force. These departments usually work on additions, improvements and repairs of property, which expense is charged to operating or capital, as the case may be.

These departments resemble outside concerns, charg-

ing for their work at cost, and it is obvious that it would not do to inflate fixed asset values with the expense of idleness incurring subsequent to increased depreciation, insurance and tax charges applying against these departments. The remedy is to relieve the service department overhead in the same manner outlined for productive manufacturing departments, thus eliminating the inflation in charges to fixed assets and the overhead accounts of the productive departments.

If the facilities in the service departments take the form of machines, the method already outlined can be readily employed. With movable facilities, if it is impractical to attempt to measure the idle facility hours, it would then be necessary to absorb such percentage of eligible overhead in costs as the actual man-hours worked bears to the possible or standard man-hours.

If it is to be noted in this discussion, we have used the percentage on productive labor method of overhead distribution and the relief for idle facilities based upon facility hours. It is advisable wherever possible to use facility hours as a measure of idleness. If it is possible to use facility hours as a basis in arriving at percentage of normal and abnormal idleness, it may be necessary to absorb such percentage of eligible overhead in costs as the current production bears to maximum production. This method, however, does not take into consideration the inefficiency of workers, which might have the effect of eliminating more expense than the used time would justify.

In establishments using the machine rate method of distributing overhead, when actual burden exceeds predetermined burden charged to costs, it might be assumed that the entire difference represented cost of idleness. In this we do not wholly concur, because in originally setting up the machine rate, certain items included therein must necessarily have been established, and this difference may represent inaccuracies in the forecast of these items. It is also for this reason that the writers do not advocate the use of the machine hour rate multiplied by the idle hours in computing the relief for idle facilities.

Another reason against this method is that apparently no distinction has been made between the fluctuating and non-fluctuating items in the rate. Using this rate without eliminating the items that fluctuate with production would result in excessive relief and would reduce costs artificially.

The writers have attempted in their suggestion to utilize the practical features embodied in the machine rate methods by using facility hours and eliminating fluctuating items of expense.

Having discussed the expense of idle facilities from a standpoint of normal and abnormal idleness, this paper would not seem complete unless the possible methods of reflection in the accounts were briefly enumerated, as follows:

1. Inclusion of normal and abnormal idleness in cost of manufacture.
2. Inclusion of normal idleness only in cost of manufacture, and disposing of abnormal idleness in one of the following manners:
   (a) Charging direct to current profit and loss statement.
   (b) Charging direct to surplus account,
   (c) Charging direct to reserve for idle facilities or contingencies.

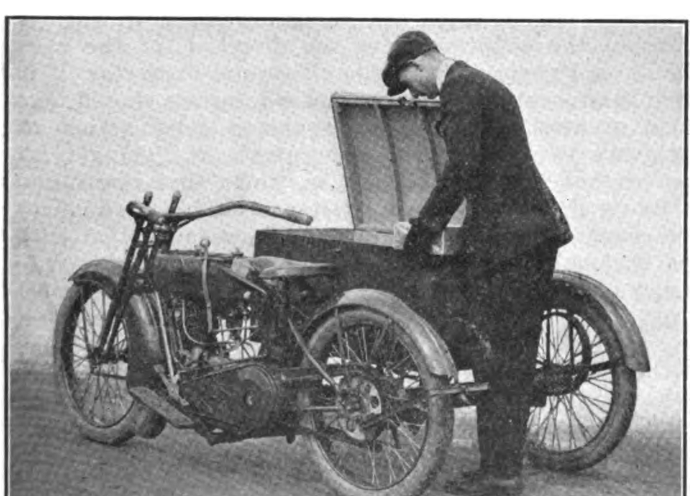
In concluding this paper the writers wish to express their earnest desire that they may have been of some assistance to the members of the association in solving some of the problems connected with idle facilities.

We feel that in these days of industrial depression our subject should be of paramount importance to the industrial executive or financial manager who is ever watchful and eager to ascertain actual conditions regarding the employment of his productive units and how their non-employment is reflected in the cost of his product.

Improved methods of dealing with industrial problems can come only from careful studies coupled with a knowledge of actual conditions. Progress in cost accounting, as in all other lines, must come by degrees and one step leads to the next. We trust that the above analysis of the problem of idle facilities may constitute a step toward the ultimate solution of all problems in connection with this subject.

A Commercial Model Motorcycle

THERE has been some feeling among motorcycle manufacturers recently that a definite attempt should be made to broaden the sales field of the motorcycle to more fully include commercial utilities. A manifestation of this feeling appears in the new one-cylinder model recently added to the Harley-Davidson line. This machine has been designed primarily to meet the requirements of commercial service. It is specially adapted to use for delivery purposes, for telephone company linemen and trouble "shooters" and similar classes of work.



Harley-Davidson model 21-CD with side car designed for commercial use

The construction and design are in general similar to that of the regular "74-in., magneto-equipped, V-twin" machine, except that the rear cylinder is removed in this commercial model. The bore is 3 7/16 in. and the stroke 4 in., giving piston displacement of 37 cu. in.

The machine is designed for an average speed of 25 to 30 m.p.h.

A SUNSHADE visor which comprises a light but rigid frame of U-section steel, electrically welded, covered with Du Pont Double Texture Rayntite fabric, padded to prevent wrinkling and sagging, has been brought out by the Troy Sunshade Co. The fixtures are so designed as to permit of adjustment of the visor to suit the driver's convenience. The visor is finished in brush-applied baked enamel with nickel-plated wing nuts.

Chinese Famine Is a Boost to Automotive Industry

Realization of the meaning of transportation to the welfare of the nation is brought home to Chinese. American Red Cross building 100 miles of roads. Americans hold leadership in trade with sleeping giant of the East.

By Don D. Patterson*

THERE was a day in China, many centuries ago when the imperial rule was at its zenith, that the nation had what was probably the world's model highway system—a system that penetrated into the farthest reaches of the land for official and military usage. But the national highway system followed closely the decadence of the Empire until to-day only cart roads and wheelbarrow paths indicate its course and these, for the most part, are in an impassable condition in so far as the motor car is concerned.

It is in the matter of roads that the greatest obstacle is found for the development of the automotive transportation in this Far Eastern republic. The desire for motors has been indicated by the Chinese over a period of ten or more years, but its growth has been seriously hampered due to confinement to the ports and larger cities of the interior, where passable highways are found. The total mileage of metal surfaced roads in China does not exceed 100 miles.

This condition would be discouraging to the western manufacturers of motors and motor equipment were it not for the fact that the past two years has brought forth the beginning of what will some day be a nationwide movement for better highways. The movement has been thus far sporadic in its development and the roads that have been built are short in length and in the majority of cases widely separated.

Various sources may be credited for the impetus that has brought this about. The first modern road of any importance in the nation was that built by the American Red Cross several years ago from Peking to Tungchow as a measure of aid for the sufferers from a disastrous flood in North China. Other road projects were started and as a result in the vicinity of the capital and Tientsin may be found the majority of the modern road mileage in the country. Shanghai has also been the seat of similar developments; a municipal road built by the authorities of the International Concession provides a drive near the outskirts of the city. A second road was constructed by the Chinese military authorities, using soldier labor, from Shanghai to Woosung, where the Yangtsze River joins the ocean, a distance of eight miles.

Projects Planned

More recent projects include the construction of a highway from Tientsin, the route having already been selected, and the development of roadways in Kwangtung Province, around Canton. Foochow, an ocean port between Shanghai and Canton, has constructed motor roads within its city limits and a private company is operating a bus line. Nantungchow, known as the model city of the Yangtsze Valley, which is practically owned and controlled by Chang Chien, former Minister of Agriculture, has a road system of thirty or more miles on which motor bus lines are operating. This system is being extended rapidly. Canton has also inaugurated a motor transportation system for passengers.

The famine which is now running riot in North China has also provided for the construction of roadways. The American Red Cross is building a highway of approximately 100 miles in length in the province of Shantung and other roads are being constructed to make use of the famine labor in other sections of the stricken territory. The famine in itself has been a grim object lesson of China's great need for motor transportation. The region in which the 45,000,000 people are affected is impenetrable except to the most primitive forms of cart and wheelbarrow transportation now used in the country. In many instances food is rotting at railheads with people starving 50 to 100 miles away due to lack of transportation. The relief agencies, with the exception of the Red Cross, have failed to recognize the advantage of motor transportation for the present, in their plans for the future, and are not using light trucks when it has been demonstrated that they are practical for the work in some regions. However, the recurrence of such a famine is highly improbable with the road system now under way.

Merchants Are Leaders

Other road ventures are being organized in various parts of the country under the direction of the merchants and gentry of various cities and districts. It is from these ventures that the motor interests should take their greatest hope. Any organized construction of highways by the Chinese Government at Peking is at the present out of the question, since that institution is living a hand-to-mouth existence so far as finances are concerned and has only a dilatory connection with the various provinces, depending largely upon the efficiency of a system of graft. The merchants are the most progressive element in the country and their interest in road building may be taken as a good omen. Much of this development is centering around Shanghai, where it has foreign encouragement.

It has been suggested by foreigners in China that the motor manufacturers, particularly those of the United States, would find a greater field in China if they were able to organize a financial group that would make loans under supervision to the Chinese Government for the construction of highways. This plan, however, is hard-

*Financial Editor *Millard's Review* and former editor of *The Oriental Motor*.

ly feasible at this time due to the formation of the International Consortium, one of whose purposes is to provide foreign money for the construction of railways and highways, and to the present unsettled and corrupt state of the so-called Republic of China. Each province is for the most part a feudal entity, giving allegiance to Peking so long as the funds necessary for the maintenance of a military autocracy in the district is forthcoming. There are two governments, that of Peking and of Canton, and with such a state of affairs a highway loan would probably be a failure.

Bankers Aroused

China's future existence depends largely upon her means of communications and now that the merchants and bankers are becoming alive to the possibilities of their nation it may be expected that they will interest themselves in providing these necessities. And when they do, China will be the most fruitful of all foreign markets for the automotive industry of the west. The Chinese will not be able to offer any domestic competition, for while cheap labor exists, it is unskilled and not easily adapted to complicated manufacturing such as is involved in the making of motor cars.

There is a phase of the road development that has not been touched and that is the possibility of foreign assistance in a moral way. The present motor car distributors have done nothing to encourage the building of roads and all developments have come from the individual initiative of the natives themselves.

The dealers seem satisfied with their sales in the treaty ports and with one exception have done little or no pioneering. One firm handling the most popular low-priced American car now has a representative in the country districts of Central and North China who is pushing through on almost impassable roads, working on the principle that motor cars will bring good roads, and is selling cars in isolated districts where they are being operated successfully.

Importance of Treaty Ports

The present automotive industry of China centers in the treaty ports of the country. Shanghai has the largest number of distributing and service plants, Hongkong and Tientsin following, and Hankow, Canton, Tsingtau bringing up the total. There are small hire services in other parts of the country and branch plants of Shanghai interests are opening up in Peking, which has been heretofore served from Tientsin.

The Shanghai distributing plants are largely American and British, with one or two French concerns in the field. The majority of the standard makes of America, Great Britain, France and Italy, of both motor cars and trucks, are represented as well as the leading tires and accessories of all the countries mentioned. For the most part, the Shanghai plants are on a par with those of the larger cities of the United States, including machine work and repairs, tire servicing, and body building. The latter has come to be a large part of the industry in China, due to the inability of many of the bodies imported to stand up under climatic conditions in China and more especially the desire upon the part of the Chinese buyers for distinctive and luxurious equipages. The Shanghai plants serve Central China territory, although some extend into North China. The Tientsin industry serves North China and Hongkong has the south. The development in the south is the most backward in the country, Canton only being a motor possibility.

The sale of motor cars in China is, like all business of an import nature in the country, largely affected by the fluctuation of exchange. During the year of 1919 China imported motor cars, trucks and cycles to the value of $6,242,368, and 59.6 per cent of the total came from the United States. For the year of 1920 this total will be materially reduced due to the falling of exchange from the beginning of the year. During the latter part of 1919 one Chinese dollar would buy $1.15 in American currency, while at the present time it would take $2.20 Chinese currency to buy one American dollar.

Prices Vary Constantly

The exchange rate between China and America is continually fluctuating and consequently each shipment of cars from the United States has its price, depending upon the rate of the day when the exchange was settled. As a result two similar models of the same make may have a price varying from $100 to $500, all due to exchange. There is no way that the dealer in China can set a fixed price for the year as is possible in the United States. This causes a rising and falling demand in the motor market, depending upon the relation of Chinese currency to the American dollar or to the currency of the country from which the car is imported. Nothing can be done to remedy this until a reformation is effected in the currency system of China, which will be some years in coming.

An attempt to stabilize the industry in Shanghai is being made by the organization of a dealers' association for general protection and the advancement of motors. This association will take up also the matter of roads and is launching a plan for the establishment of an annual motor show next fall. The show will be the first in the Far East, that is, in the section east of India.

Counting the Cars

The motor population of China is difficult to estimate due to a lack of registration in some sections of the country. Shanghai has the largest, with approximately 3,000 cars and 1,000 or more trucks and motorcycles. Tientsin has approximately 500 to 700 cars and Peking a like number. Canton has only a few and a hundred or so are scattered around through the various sections. Tsingtau has probably 100 and Hankow approximately 300. Hongkong, being British, cannot be included in any estimate of China proper. A number of cars are centered at Kalgan on the Gobi Desert of Mongolia, where, under government supervision, a motor line is operated between that point and Urga, the capital of the province, half way to the Russian border. A recent order will place fifty-seven Fiat trucks in this service within a short time. The Kalgan to Urga trip over the desert takes four days and the round trip costs $300, Chinese currency.

American makes predominate the motor field due to the close proximity of the country, the more favorable prices, and the activities of the manufacturers in the export field. England is paying little or no attention to China from an automotive standpoint and most makers will deliver only a half dozen or so cars during the year. France is giving all of the attention to the field she can and Italy is following her example. However, the American manufacturers have the advantage of being firmly established on the ground and of having factory representatives in the field approximately twice each year. A number of the larger motor manufacturers of the United States have direct representatives who are permanently established in the field to assist the distributors and to organize their services. As a result even the larger British firms handle a majority of American makes.

There is one disadvantage in the field at present and that is that most of the distributors in China represent

too many makes. There are two notable exceptions in Shanghai and these, having only a few American makes, have the lion's share of the business due to their ability to push these makes and to pioneer in the territory assigned.

Future of Trucks

Motor trucks are coming in for their part of the recognition and when the day comes that China has a semblance of a highway system, trucks are going to be more important in the country than railway trains. Trucks are already in daily operation in Manchuria, Mongolia, in Kiangsu Province, in the city of Foochow and elsewhere. The truck population of Shanghai is growing rapidly and the city is supporting one public truck transportation line with a fleet of approximately twenty-five. A majority of the larger Chinese manufacturing plants are using trucks, as are the Chinese and foreign department and other stores. As Shanghai is the most important shipping port of China, the trucks are playing a large part in the movement of cargo—a part that will increase rapidly.

Gay Turnouts

The Chinese have taken up the motor car rapidly and the wealthier classes are never without them. They fill the inherent craving for display and ostentation as well as being a utility. The limousine because of its luxuriousness is the most popular and the fittings of many have given them the nickname among the foreign population of "rolling boudoirs." This type is painted a brilliant red or yellow, or perhaps a blue, pink or purple. The fittings inside are of the same color, generally in brocaded Chinese silk, and the equipment consists of silk tasseled curtains on the windows and doors, draped back, and Chinese vanity cases on the rear of the back seat, containing a full line of cosmetics, a cigarette case, matches, a mirror and other luxuries. The younger generation have taken to vivid colored sport roadsters and all young or old are addicted to speed. The Chinese chauffeur has no nerves, no conscience and the pedestrian moves slowly with the habit of centuries in only dodging wheelbarrows, carts and rickshaws, resulting in a rather large toll of daily accidents in the cities where motor cars are most numerous. Traffic problems are Chinese puzzles, figuratively and literally.

There is a great future ahead of the automotive industry in China, but it is a prospect that will take years in the realization. At the present moment China is in the throes of a business depression that is more gloomy than that of the United States for the reason that she has no organized bank system to tide her through, no organized system of business communications and her markets are largely dependent upon foreign sources. The next year or so will be slim ones for foreign business in China and the automotive industry will suffer a trifle more even than the others concerned. Rising exchange will come only when exports begin to move—and there is at present a dead calm in the export market—and that movement will only result when demand revives in the United States, Great Britain and, to a lesser degree, Europe.

China should be cultivated by American motor manufacturers, encouraged to build roads and kept closely in hand. When the road development does come, China will offer one of—if not the greatest—largest export motor markets of the world. She has 400,000,000 in population and while that population is for the most part possessed of only a scant buying power, if there was only one in every 400 who could buy a motor car every three to five years it would tax the capacity of the manufacturers of the United States and other countries to fill the demand.

Hundred Passenger Plane Reported Wrecked

It is reported that the enormous Italian flying boat with six 400 hp. Liberty engines and with seating accommodations for 100 passengers—recently completed and described below—was wrecked during its first ascent on Lake Maggiore. *The Aeroplane* of London, whose editor made a trip to Cesto Calende, where the trial was to take place, prints several views of the wreckage. The Caproni Works will not admit the destruction of the machine, the official report being to the effect that the machine made a flight of a mile and on descending was damaged so that it was retired for slight repairs. The unofficial report was that pilot Sembrini took the machine off the water, got her up about 60 ft. and then gently put her nose down and continued so till she drove it under the water. Mr. Gray says, "considering that she had four Liberty engines on her forward planes and four more aft, with very small elevators and yards of space between the engine masses, it must have been very difficult to counteract her enormous longitudinal moment of inertia, and so the story has every semblance of truth." The wreckage which he photographed was said to be that of an ordinary triplane on floats which about the same time made a complete submersion, but it bears remarkable resemblance to the published photos of the eight-engined machine.

According to a report by U. S. Commercial Attache H. C. McLean at Rome, the huge flying boat was made up of three triplanes with the tails removed, placed one behind the other. Between the wings of the rear set of planes were placed the rudders, while the elevation of the machine was controlled by ailerons on all of the wings. The length of the ship was 75 ft. and the wingspread 108 ft. It was equipped with eight low compression Liberty engines of 375 hp. each, making the total available power 3000 hp. Its weight was about 16 tons and it was designed to carry a load of 10 tons, making the total weight 26 tons.

The cabin, which was entered through a door at the stern, was 7 ft. high, about 8 ft. wide and ran the entire length of the ship. A narrow aisle ran down the center, with comfortably upholstered seats on both sides. At the bow a small compartment was provided for the commanding officer, while a ladder led to the pilot's post, immediately behind and above, from which all operations were controlled. Provision was made for two pilots, one of whom was to be in reserve, and between the two seats was located an electrical switchboard for the transmission of orders. Two levers at the right permitted the pilot to control the engines without reference to the engineers in case of emergency.

The engines were mounted in two groups, four in the first set of planes and four in the last. In each case two engines were placed back to back directly in the center, with one on each side, the central engines being equipped with four-blade propellers, and those on the sides with two-bladed. Provision was made for one engineer for each set of engines. During its first trial the ship was to carry only sand ballast.

It was estimated that the total cost of the new airplane exceeded 4,000,000 lire.

The Spirit Behind the Dealer Contract

An automobile salesmanager recently discussed dealer relations in an informal way and said some interesting things. "To exercise control over dealers," he said, "it is primarily necessary to convince them you are trying to help them. It is the spirit behind the contract that counts."

By Norman G. Shidle

NOT long ago I had an interesting talk with the general sales manager of one of the largest automobile concerns in the country. The talk was specially interesting because of the universal increase in attention being given to marketing, dealer relations, etc., and because this sales manager has been conspicuously successful in carrying out his work.

Discussing the matter of marketing, he outlined some of the plans which he is using to help dealers in making sales and in decreasing sales resistance. A number of these plans depend very largely upon the co-operation afforded by the dealer and the attitude taken by the dealer toward the help extended. Some of them, in fact, seemed to call for a very strong control of the dealer organization by the manufacturing sales department.

When some of these plans had been outlined, the thought came to my mind that it might be very difficult in many cases to get the dealer to operate so closely under the supervision and control of the manufacturer; that the dealer would be likely to feel that his own way was the best and to resent too close supervision. So I asked this sales manager if he didn't have a good many troubles on this score. I said that it seemed to me as though the plans might work more successfully if he were operating factory branches instead of dealer; but that under present conditions such control appeared difficult.

"Well," this sales manager replied, "that is not necessarily as true in practice as you might think. It depends very largely upon the attitude and actions of the manufacturer as well as upon the sort of dealers that you have.

"The primary necessity is to convince the dealers that you are trying to help them; that you understand how closely bound up with their success is your success. This must be done in actions as well as in words. During the last few years, for instance, when all the dealers were asking for many more cars than could possibly be supplied to them, I made it an invariable rule to treat every dealer in exactly the same way.

"As you know, we have worked out a quota system on a scientific basis, so that our production can be proportioned to the various territories in a fair and accurate manner. On the basis of this quota system, we proportioned our cars during the entire period of peak demand. We gave the same treatment to the country dealer that is accorded to the city dealer, even though the latter had enormous demands at a certain time. Through it all, we kept the confidence of our dealers, because, even when they wanted extra cars most and couldn't get them, the big dealers felt in their heart that we were on the level. They knew that while they couldn't get more than their share, no one else could either. In other words, to put it frankly, every individual dealer knew we were square because we wouldn't cheat for him.

"That is just one example of how by actions dealer confidence can be built up. And I often think actions are of more importance than house organ messages in many cases.

"Take the matter of dealer contracts, for instance, about which there has been considerable stir lately. The bad practices of a few manufacturers and dealers cause a lot of disturbance. It is foolish to talk about the elimination of a cancellation clause from the contract. It costs us money to establish a dealer; we invest a certain amount in every new dealer we take on, and that investment must be protected. If we find we have an inefficient dealer it is not profitable either to him or to us that he should continue his connection with our organization.

"As far as suddenly cancelling a dealer's contract is concerned, the manufacturer has nothing to gain from cancelling the contract of any dealer who is doing satisfactory work. His success is our success. In fact the manufacturer cannot possibly be successful unless he has an efficient and effective dealer organization.

"That is the fundamental to which the whole thing boils down. A sound basis of mutual understanding and mutual desire for a square deal is far more important than any words in a legal contract. The perfect contract can never be written in black and white. It is the spirit behind the contract that counts."

Perhaps much of this sounds like theory. Probably some one will object that all these general ideas are all right, but that it is different when it comes to actual practice.

There are some things in this world which cannot quite be reduced to statistics or figures. An understanding of certain abstract factors is necessary to success in modern merchandising. The results obtained from such an understanding will be very practical, however, as can be noted in this case.

It will be admitted that there has been considerable dealer unrest during the last year. The dealer personnel of this manufacturer, however, for 1921 comprises 98 per cent of those associated with him during 1920, a remarkable record in view of the conditions. Moreover, this bunch of dealers has been selling more cars than the factory can produce for over two months.

These facts go a long way toward emphasizing the importance of the spirit behind the dealer contract.

THE Union Petroleum Co. is marketing a new cutting oil known as Wilkut. It is claimed to be a better coolant than lard oil. It requires no mixing or diluting, is sterile, does not corrode bronze or other bearings of machines or discolor work. The oil is transparent, enabling the workman to see his work at all times.

Production Manager's Relation to Fatigue Studies

New methods of observation for fatigue studies were used in recent British investigations. This article discusses the general application of these principles and indicates the function of the production manager in translating the results of such studies into practical operations.

By Harry Tipper

FROM time to time in these articles reference has been made to the question of fatigue and the relation between the fatigue established, the hours of labor, the physical requirements of the operation and the surroundings. In considering these items, reference has been made to the investigations conducted by the medical profession, the value of these investigations to industry and the limitations of them.

In Great Britain the long development of the industrial system from its early beginning, the crowded condition of the country and the character of the climate have combined to make the problem of fatigue of more importance from the physical standpoint. During the war medical committees were appointed to inquire into the health of munition workers, the conditions in the munition factories, and to make recommendations regarding changes in the character of the factory surroundings and hours. This work has been continued by the Medical Research Council, which is a department of the government. This council has issued an extended report upon the atmospheric conditions and their effect upon fatigue.

The principal points of interest in this report are the new methods adopted for observation and the extended investigations into wet and dry temperatures, cooling powers, air velocities and similar conditions entering into the atmospheric surroundings of the worker. Interim conclusions have been arrived at concerning the effect of these variations upon the fatigue.

The present report is confined to the boot and shoe factories, but the methods of making observations would be of interest in a great many other cases. The report shows the difficulty of separating one factor in the surroundings and noting its effect without the other factors entering into the conclusions. It also indicates the intimate relation existing between the surroundings, the character of the clothing worn by the worker, the condition of the worker's health at the time, and so forth.

The report lays emphasis on the government of the air in the work room, and a variation in the temperature naturally associated with such movements has elements of great importance in lessening the fatigue and increasing the co-operative powers of the worker.

In order to determine the conditions affecting the loss of heat the board used the kata-thermometer, which measures the cooling power of the air. The dry kata loses heat by radiation and convection; the wet kata by radiation, convection and evaporation. This makes it possible to secure some indication of the ability of the skin to exercise its cooling effect. The measurements are made in the immediate location of the worker. The comparisons are not exact because of the effect of the clothing and the work itself upon the loss of heat from the body.

Mainly, this report shows what a long way we have to go before we will be in a position to determine accurately the effect of the surroundings upon the physical conditions of the worker.

It is obvious that our knowledge is confined to very elementary conclusions of a general character concerning the temperature of the air, the moisture in the atmosphere and its movement. It is not surprising that the conditions in various manufacturing establishments should be so different when the best investigations of the medical man have been able to prove so little in respect of the required elements.

In this country the researches of the medical man into fatigue have secured little attention from the business man, so that even what is known at present about the effect of fatigue upon production is not fully considered in the working out of the factory organization. The importance of examination of fatigue has not been appreciated by the manufacturer in its effect upon production efficiency, and therefore the production cost.

Very little has been done in the examination of distinct occupational groups within the various industries and the effect of the particular work upon which they are engaged, except in those special cases where the character of the work has been obviously dangerous to the health. The reports which have been issued from time to time in this country and abroad are still somewhat general in their examinations, and not sufficiently exact to be of much benefit to the production manager in his attempt to determine the practical conditions of his organization.

There is lack of co-ordination between the researches of the medical man and the various engineers concerned with factory building and organization, so that many of the researches are academic in character and have not resulted in the development of practical measures designed to overcome the difficulty.

Heating engineers, ventilating engineers, building engineers and medical men interested in industry must co-ordinate their researches very much more closely if the discoveries in the one case are to effectuate practically in the other.

There is not much value to the production manager in the observations of the medical man, unless these can be translated into the practical construction and the equipment of the factory without an unbearable expense. The desirability of proper light, heat, ventilation and movement of air within the factory is admitted by all industrial engineers and production men.

The progress in factory building and lighting indicates the attention which has been paid to these matters, but the construction of a factory offering the best conditions possible, for the reduction of fatigue on account of the surroundings, depends upon the combined efforts of these various engineers and their knowledge of the medical researches. This demands a co-ordination of effort in research which has not been secured at present and which has minimized the effects.

The conclusions derived from the researches into the physical surroundings and their effect upon the physical condition must be accepted with reserve at the present time, because they are always complicated by the mental factors entering into the condition of fatigue. All that they can do in themselves is to establish the broad general necessities in regard to the physical conditions of the work and the surroundings in which the work is done.

The limitation of physical effort to a reasonable average requirement, the provision of proper floors where the work requires continuous standing or walking, provisions for changes in the position where the work is concentrated, proper arrangements for light, the elimination of fumes and smoke, continual replacement of the air and a proper amount of heat must be determined for an average individual under the average requirements in the factory.

These general matters can be determined so that the conditions of work minimize the fatigue to some extent. They do not alter the accumulation of fatigue on account of the character of the work itself, and the incentives which are developed by the work.

The processes of their practical working out in factory organization is a slow one and they can only be improved detail by detail, so that their effect upon the production efficiency is not very marked at any particular period. They are valuable because it is obvious that any improvement which can be made in factory organization in agreement with the known laws of health will eliminate some of the difficulties under which the workers labor, and to that extent prevent accumulated fatigue or loss of health from other causes.

Naturally the working out of organization improvement within the factory depends upon the advance in the engineers' capacity to provide practical methods of improvement. This question of physical fatigue as influenced by the surroundings and conditions of the work is one which must be solved by the engineer and the production executives.

The researches which are being made from the medical standpoint can be understood readily by the engineer who will give some study to the matter, and they will be of great value to him in their suggestion of present deficiencies and the possibilities of improving present conditions.

There should be a larger interchange of information along these lines and a larger discussion between those industrial engineers who are interested in examining human efficiency and those medical men who are interested in industrial health. Such interchange would benefit the practical situation by the general understanding of the conditions secured on both sides, the better direction of future research and the better examination of practicalities.

Individual the Most Important Factor

THE general outlines of the Studebaker co-operative plan are well known throughout the industry. The plan provides, among other things, for stock owning by employees, bonuses for continued service, pensions, vacations, checks, etc. The plan has been in operation for over a year and a half and is being conducted with considerable success.

A recent informal conversation with Dr. C. A. Lippincott, who has charge of the administration of the plan, however, brings to light certain factors in regard to industrial relations not discussed so frequently as those pertaining to group labor policies. Dr. Lippincott believes very thoroughly in the essential soundness of the Studebaker co-operative plans. They are economically and ethically sound and for that reason operate to the mutual advantage of both the corporation and the employees.

There are certain factors involved in the matter of industrial relations, however, not included in such plans. The relation of the individual to his job, for instance, is not accounted for by any group plan. The question of the mental effect of continued performance of the same simple operation day after day, the possibilities for promotion for the average worker through the experience gained on the job he is doing, the effect on the individual of the continued tendency toward specialization—all of these things constitute industrial problems which can be handled successfully only through the proper study of the individual.

Dr. Lippincott believes that the work his personnel department is doing in regard to the handling of individual complaints, the adjustment of minor working conditions, the changing of a man from one job to another when he becomes tired of the monotony, etc., is of equal if not greater importance to that of administering the co-operative plans.

He says that these problems relating to the individual are as yet solved only to a very limited extent. His department recognizes the presence of such problems, however, and is gradually attempting to work out a solution through careful study and intelligent analysis of the various factors involved.

This statement of the importance of a study of the individual is specially interesting as coming from Dr. Lippincott, since he is associated with the administration of highly successful group labor plans. In other words, it emphasizes the essential importance of the individual as the fundamental industrial unit, without minimizing the comparative value of the broader and more readily established mass methods of dealing with the labor situation.

THE new British motor taxation is yielding larger sums than was anticipated. During January and February the total receipts amounted to £7,092,400. The statistics indicate that owners of commercial road transport vehicles are contributing over 50 per cent. of the revenue from the new taxation.

Tractor Industry's Big Task

"WE know that power farming is the surest method of reducing production costs. If the farmer and public as a whole do not know this fact it is our own fault."

This was the answer of Finley P. Mount, chairman of the Tractor and Thresher Department of the National Implement and Vehicle Association to the comment recently heard that low price of farm produce was slowing up tractor sales. The answer appears to be complete and it also appears to be a justification of the recently established Power Farming Bureau by this association. This bureau is to supply accurate information concerning power farming and is to cooperate with the farm press and with agricultural institutions and organizations to advance the power farming idea.

It is a big undertaking to re-educate a great public, like the farmers of this country, to a new process of operation. Just how large a task this is one can judge by noting how slowly manufacturing plants, mercantile establishments and other business institutions accept devices and machinery which clearly show an ability to increase profits. The advertising task before the tractor industry is a considerable job.

Recommended Practice in Hub Design

THE controversy between those who favor standardization and those who would leave everything to the judgment of individual engineers is as old as the effort to create standards. To-day most engineers occupy a middle ground; they favor standardization so long as it does not tend to throttle initiative on the part of the designer, but they oppose it when the tendency is to trespass upon ground which the engineer considers strictly his own.

It is, as a matter of fact, extremely difficult to draw the line between things which should and should not be standardized, while commercial and other considerations complicate the problem. It may be said in general that standards are necessary where interchangeability is required, or where units made by different groups of manufacturers must fit together, but this need not interfere with initiative or with originality in design. For example, several dimensions of the flywheel and its housing have been standard for some years and are quite generally used to the advantage of all concerned, but many non-standard flywheels and housings are used, and there is nothing to prevent any maker not so benefited from using other dimensions if he desires.

So long as all the parts for a given machine are made in the same plant they are readily made interchangeable, though even then certain standards must be established and maintained, but when parts for a given assembly are made in different plants, standardization becomes a necessity.

Interchangeability and mating between parts of like or similar character brought about by standardization has been one of the largest and most important elements which has made the modern low-priced American automobile possible. In England, where there is very little standardization and every manufacturer makes, to his own design, nearly all the parts of the car, the automobile is relatively high priced and its field of usefulness is correspondingly limited.

The enormous parts business which has developed in this country has been made possible by a willingness of manufacturers to co-operate in making parts that will fit together. This interchangeability has made possible large quantity manufacture and correspondingly reduced price to the benefit of all concerned. It has, perhaps, limited originality to a slight degree, but the benefits gained far outweigh the slight disadvantages, and the great volume of business which has resulted has widened rather than narrowed the field for the engineer, or perhaps we should say has provided far more work for engineers to do than would otherwise have resulted.

Axles and wheels are made, for the most part, by different groups of manufacturers, and it is not at

all surprising that these groups find it necessary to bring about standards which will enable their respective products to fit together without innumerable small changes which in themselves are of little consequence so far as the design is concerned, but which cause no end of trouble and needless expense in changes in tools, patterns, etc.

The remedy is, of course, the adoption of standards or recommended practice in hub design. Since the hub design depends, in turn, upon spindle and bearing sizes, certain selections in this regard are necessary and have been made. Since two types of bearings are available, two sets of standards or recommended practice are to be proposed at the coming semi-annual meeting of the Standards Committee of the Society of Automotive Engineers, one intended for the use of inch dimension roller bearings, and the other for metric size ball or roller bearings.

The subject has been given thorough consideration by those interested, and the proposals to be made involve chiefly or wholly connecting dimensions (not details of design) and are said to have the approval of all prominent makers of ball and roller bearings and wood and steel wheels, as well as of many axle and truck manufacturers. In arriving at the recommendations to be made in the report of the Truck Division of the S. A. E. Standards Committee, all arguments for and against the adoption of recommended practice have been heard and, except for those who oppose any standardization, are believed to be composed.

No one who opposes the use of this or any other recommended practice is obliged to use it, but if there are any valid objections to the recommendations offered, opportunity to express them will be afforded at the forthcoming meeting. Those who desire to see the recommendations accepted by the Standards Committee and the Society should not fail to attend the meeting, in order that the vote may be representative and not biased by a minority who do not favor the recommendations.

AUTOMOTIVE INDUSTRIES believes that hub standardization is desirable, but has gladly given much space to those who oppose it, as well as to its advocates. We are inclined to the belief that the report now agreed upon by the Truck Division is worthy of acceptance as recommended practice, and think the Society is to be commended for bringing together conflicting elements. Those who are vitally concerned, however, are the ones who will either use or be handicapped by the proposals, and both sides should be fully represented in the final vote.

"Scratching Gravel"

THERE was a business man in a town of about 100,000, who had a large corner office on the third floor of the largest office building in town. He had occupied that office for three years.

The other day an automobile salesman called on him in his office, told him about the car and sold him a car the next day. Although financially an excellent prospect, this man had not owned a car before. But this was the first time during the three years that an automobile salesman had ever called on him or approached him in regard to buying a car.

This business man was interested, so he asked the salesman how he happened to call on him. The salesman replied that until a month before he had been a salesman for office furniture. He had always called on executives in search of a market for his product. When he started to sell automobiles he naturally followed out the same plan as before.

The experience of this business man would indicate that the actual listing of prospects has not come "naturally" to enough automobile salesmen. This story is told by a well-known salesmanager, who cites it as an instance of what he believes to be the essential factor in bringing sales back to normal—"just naturally scratching gravel."

A Standard Sprocket Tooth Form

ONE of the most important pieces of standardization work now under way is that on roller chain sprockets. Heretofore most of the companies manufacturing roller chains have had their own form of sprocket tooth, and, while all used the standard pitches and widths, the sprockets of one concern were not strictly interchangeable with those of another. Moreover the old style of sprocket, in which the chain, when worn, bore only on a single tooth of the sprocket, was not very efficient, because with such contact the pressure on the roller and tooth was necessarily very high, and the wear, therefore, was rapid.

In the new form of sprocket tooth, already agreed upon by the chain manufacturers and which will undoubtedly be ratified shortly by the standardizing bodies, the pressure between chain and sprocket will be divided between a number of teeth whether the chain is new or old. When the chain is new, the rollers will bed at the bottom of the tooth spaces, whereas, when the chain is worn, contact will occur farther up the side of the teeth. The conditions of contact will, therefore, be substantially equally good whether the chain is new or old, an advantage which has long been confined to the silent type of chain.

Roads and Reputations

A PROMINENT highway engineer told a group of his fellow workers recently that their job was to build roads so that they would last. "Ten years from now," he said in effect, "the people won't care about how large your appropriation was with which to build these roads; they won't care about anything except the condition of the road. You can serve the people best by building roads that will stand up.

"It is upon that fact and that alone that your reputations will rest. The people will want a road; not a memory. Traffic will probably get heavier, but you must build the roads to meet the conditions. It would not be economically proper to expect traffic to limit itself by the roads." This is the point of view which means permanent progress for motor vehicle transportation.

Square Deal on Tax Aim of Industry

Equal Distribution to Be Urged in Plea

Directors of N. A. C. C. Complete Plans for Hearing Before Senate Committee

DETROIT, May 9—Directors of the National Automobile Chamber of Commerce at the May meeting in Detroit last week formulated plans for its fight before the Senate finance committee on May 16 on the proposed tax increase on automobiles and trucks. The efforts of the organization will be supplemented by those of allied interests, the National Automobile Dealers' Association already having asked for and been granted a hearing. The Motor and Accessory Manufacturers' Association and the Rubber Manufacturers' Association also will be represented at the hearings.

Directors of the National Automobile Chamber of Commerce took the position that the matter was one of such grave importance to the automotive industry as well as the country in general and that the industry is of such magnitude that the separate units should be given opportunity to present their claims individually and preferably on separate days rather than attempt to sum up all the issues in a short conference of a general committee. As a result the interests of the chamber will be represented by Chairman C. C. Hanch of the Tax Committee, George M. Graham, who will present the claims of the truck manufacturers; J. Walter Drake, of Hupp Motor Car Corp., and H. H. Rice, who succeeded R. H. Collins as president of Cadillac.

Hanch Outlines Appeal

"We are seeking only a square deal for one of the greatest American industries," said Chairman Hanch. "An equitable distribution of taxation is our plea, for the moment Congress puts the stamp of special taxation on an industry it brands that industry as illegitimate. It is our contention that automobiles and trucks, as President Harding so aptly put it, are essentials in the modern scheme of life, and we insist that taxation should be based on exactly the same reasoning as in the case of every other means of highway transportation."

The directors took exception to the plan of Secretary Mellon for a Federal license system in horsepower tax as an injustice to the industry which they contend is taxed to a greater degree than any other. Favoring a sales tax, preferably on retail sales, the directors will protest vigorously against any special or discriminatory tax and will urge the removal of the present excise tax. The program as outlined and made public three months ago will be urged upon the Senate committee.

Aside from the taxation problem, the directors spent much time in discussion of the location for the annual New York show with opinion divided as between Madison Square Garden and the Eighth Regiment Armory. The matter finally was passed over until the June meeting with the feeling prevalent that the armory probably would be favored on account of the immense floor space available unhampered by posts or supports.

A campaign of education with the idea of bringing full realization of the magnitude of the automotive industry and the fact that the motor vehicle is a necessity and indispensable, also was planned by the directors to cover the entire country. Facts and Figures of the Automobile Industry for 1921, the pamphlet published by the chamber, will be sent out to 45,000 bankers, chambers of commerce, industrial leaders and universities and

Berliet Gets Ten Years to Pay Off Creditors

(By cable to AUTOMOTIVE INDUSTRIES)

PARIS, MAY 9.—By permission of the French courts, the Berliet Co. has been allowed to make an arrangement with creditors whereby its debts will be paid within a period of ten years together with normal interest. Under this plan the company will continue in business.

The Fiat factory has been reopened after being closed for more than a month. The men returned under the owners conditions.

CALL OFF TOOL CONVENTION

WORCESTER, May 7—The spring meeting of the National Machine Tool Builders' Association which had been arranged for May 19-20 at the Traymore in Atlantic City has been finally canceled because of the condition of the industry, according to Carl F. Dietz, vice-president and general sales manager of the Norton company and who is secretary of the big organization.

WILLYS LIGHT PRICE CUT

TOLEDO, May 9—The Willys light division of the Electric Auto-Lite Corp. announces a reduction of $100 in the price of the Willys light. The cut has been made to meet the sharp price liquidation in the farming industry. The company asserts that for the time being the light will be sold at a loss.

Anti-Dumping Action Unfair, Say French

Blame Glutting of European Market on Heavy Shipments from America

PARIS, May 1 (By Mail)—Motor Transport Corps First Reconstruction Park, at Verneuil, the biggest organization of its kind left behind by the American Army in France, has been sold after standing idle for twenty-nine months. This park was built in four months by the Motor Transport Corps, and at the time of the Armistice was running with 3500 soldiers, all of them skilled hands, while 1500 German prisoners were working on the construction of additional buildings. The total area was 355 acres, and the park was laid out for the complete overhaul and reconstruction of motor vehicles of all kinds.

Immense stocks of spare parts were kept at Verneuil, and although the American Army is supposed to have prepared complete inventories, the French authorities never knew how much material was contained in this camp. M. Doucet, who had purchased the park from the French Government at a cost of 55,000,000 francs, admitted in an interview with the correspondent of AUTOMOTIVE INDUSTRIES that he did not know how much material he had bought.

The only definite information obtainable at the offices of the company was that there were 9000 unopened boxes of Ford parts. A representative of the Ford company in France who had an opportunity of opening some of these boxes stated that most of the parts were ruined by being left out in the open. On this account his company refused to purchase.

Parts for Many Cars

The biggest stocks of parts, according to the officials of the purchasing company, are for the following cars and trucks: Cadillac, Cole, Dodge, Ford, F. W. D., Garford, G. M. C., Kelly, Mack, Nash Quad, National, Packard, Peerless, Pierce Arrow, Riker, U. S., White, Holt tractor and Harley-Davidson and Indian motorcycles. There are very few complete vehicles, for Verneuil existed only for reconstruction and supply. The park, however, had machine shops of such a complete nature that it would have been possible to build automobiles in them. All this machinery is now for sale, and the Austin buildings will also be disposed of.

The park contained 45,000 solid tires and about 60,000 penumatics when taken

Lower Prices Stir Renewed Buying

New York Business Shows Sharp Ascent

Sales Rise High Over Previous Months in Marmon and Jordan Salesrooms

NEW YORK, May 7—Marmon and Jordan, which announced substantial price reductions a week ago have had brisk sales both wholesale and retail in the New York territory.

Inquiries of prospects visiting the salesrooms, and of others using the mails or telephone began almost as soon as the salesroom opened Monday morning, the price reduction ads having appeared in the Sunday newspapers. Throughout the week, sales of both cars have run high in comparison with recent months.

Marmon has received several applications for dealerships in the territory. Jordan, which was seeking expansion of wholesale business, has placed several additional dealers and has received numerous applications which are still under consideration, as a result of the lowered price.

Jordan had 40 people in the salesroom Tuesday evening, two or three of whom bought cars on the spot. Since then not a single day has been a "goose egg," as far as retail sales are concerned. In other lines, the week has been considerably ahead of several recent weeks in the retail sales despite the fact that it has rained almost every day. Practically all sales made have involved a trade, but the used car market is active and fairly good prices have been obtained.

There is a noticeable improvement in truck sales. One dealer sold 24 new trucks and six used trucks in April. Another sold within five of his April, 1920, record, and his sales for January, February, March and April were within 10 per cent of those of a year ago.

Dealers who have sold trucks since Jan. 1 have had to trade in most cases and state frankly that they have made more liberal allowances than those prevailing a year ago.

Accessory and tire business is good. One large house, whose sales for several years have quite closely paralleled those in the passenger car field had a first quarter's business which was 60 per cent of 1920. April sales were better than that.

GERDIS OBENBERGER TRUSTEE

MILWAUKEE, May 9—J. F. Gerdis, who was appointed receiver of the John Obenberger Forge Co., Milwaukee, upon involuntary bankruptcy proceedings, has now been elected trustee of the bankrupt estate under bond of $25,000.

COLLINS TAKES OVER OLD CADILLAC PLANT

DETROIT, May 11—R. H. Collins, who retired from the presidency of the Cadillac division of the General Motors Corp. to head the Collins Motor Car Co., a $10,000,000 Michigan corporation, has purchased the Cass Avenue plant occupied by Cadillac before that company moved to its new location. Negotiations for the purchase were closed yesterday.

Collins stated to-day it was too early to make any announcement regarding the type of car he expects to build beyond the fact that it will be a high grade automobile which is expected to be in production by Jan. 1. He will not begin work at his own plant until he finally severs his relations with Cadillac, July 1. He still is in full charge of the General Motors company and will continue until that date. He declined to state the price paid for the property.

Collins will be allied in his new venture with W. C. Durant, who is at the head of Durant Motors, Inc. An early announcement is expected from Durant regarding the location of the main plant for the production of his car.

Strike Threats Slow Sales in Kansas City

KANSAS CITY, May 9—The last week of April was a big one in retail sales of motor cars in Kansas City, some firms running their totals into figures large for any season. There had been a sharp upturn on volume in many lines in April, but motor cars as well as most other lines, suffered sharp depression the first week of May.

The announcement of price reductions of motor cars, was called a factor in the depression of sales. But there were many other factors, perhaps even more impelling. One of these was the existence of a delicate situation in several industries, with strikes threatened.

LOCK SEAM PATENT UPHELD

CHICAGO, May 9—Judge Killets in Federal District Court has handed down a decision sustaining patents 1,034,954 held by the Dallas Brass & Copper Co. on their lock seam tube forming machine in a suit against the Motor Products Corp. and the Diamond Mfg. Co. of Detroit. Tubing made by this machine is used principally in the radiators of automobiles.

Chevrolet Reduces Prices on "490" line

Will Now List Within $100 of Pre-War Level—Look for Sales Increase

NEW YORK, May 7—Speculation concerning the plans of the Chevrolet Motor Co. regarding prices was set at rest yesterday by announcement of an average reduction of 21 1/3 per cent for the "Four-ninety" models. The new price list follows:

Touring car, $645; a reduction of $175.
Roadster, $635; a reduction of $160.
Sedan, $1,195; a reduction of $180.
Coupe, $1,155; a reduction of $170.
Light delivery wagon, $645; a reduction of $175.

These prices bring the Chevrolet back to within $100 of those which prevailed in April, 1917, before the United States went into the war. In that year the touring car sold for $550. In 1918 the price was raised to $685 and it had stood at $795 for nearly two years.

The Chevrolet company announced March 21 that if 50,000 cars were sold between Jan. 1 and Aug. 1, a refund of $50 would be given to each purchaser. This refund will be paid at once to all purchasers since the announcement was made instead of waiting until Aug. 1.

The Chevrolet price cut was more drastic than had been expected and it came somewhat unexpectedly, following close upon reductions made on Marmons and Jordans. It is expected by the company that the demand at the lower price will largely increase production with a consequent lowering of overhead which will justify the decreases.

Oakland Second of G.M.C. to Announce Price Cut

PONTIAC, MICH., May 9—The second of the General Motors Corp. subsidiaries to announce a reduction in prices was the Oakland Motor Car Co., which put a new schedule into effect to-day. The cut is $250 on each model or 18 per cent on open cars and 12 1/10 on closed.

The touring car and roadster which were $1,395 now will sell for $1,145. The coupe and sedan which were $2,065 will sell for $1,815.

The cut in prices followed closely a visit to the plant by the chief executive of the General Motors Corp.

STEVENS-DURYEA NEAR NORMAL

SPRINGFIELD, MASS., May 7—Stevens-Duryea, Inc., has increased production 50 per cent and has taken back 150 men. It is announced that the plant will be running on a normal basis by the middle of the month.

Manufacturers Take Up Contract Points

Clauses to Strengthen Dealer Credit and Customer Relations Favored at Meeting

DETROIT, May 10—In an all-day session, characterized by harmony and an apparent desire to cooperate more closely, committees representing the National Automobile Chamber of Commerce and the National Automobile Dealers Association, wrestled here to-day with vital problems brought out by the dealers. At the end of the meeting adjournment was taken until next month pending reference of the suggestions and decisions to the parent organizations.

The meeting was presided over by W. C. Sills, general sales manager of the Chevrolet Motor Co., while H. B. Harper, Philadelphia Overland dealer, acted as secretary. Although morning and afternoon sessions of the conference were executive and a formal statement issued to-night gave no details of the meeting, reports filtering from the conference room indicated it was a field day for the dealers.

Six points brought up for discussion by dealers, according to unofficial information, were received with apparent favor by the manufacturers' representatives, their attitude indicating the committee recommendations would be highly satisfactory to the dealers. Requests of dealers and suggestions for disposition of points at issue were formulated at a meeting of the N. A. D. A. directors yesterday. At the same time the N. A. C. C. directors met and outlined the course of action.

While little information concerning the meeting was available and no intimation was given as to the attitude of either side, the situation was well stated by President Jesse A. Smith of the N. A. D. A., and General Manager Reeves for the N. A. C. C.

Both Sides Seek Solution

"The time is here to sell cars," they said, "and we all realize that success in the merchandising of our products must and can come only through close cooperation. The prosperity of the factory is dependent on that of the dealers, and the latter's success depends solely on his treatment of customers and prospects."

The discussion ended with both sides anxious to find the solution, but the situation proved too formidable for quick decision. "It is the country dealers who are up against the real problem in the used car business," said President Smith, after the meeting, "and when you consider they comprise a big percentage of dealers of the country, you get some idea of its importance. We in the cities where proper effort is made can keep our used car stocks in fairly good shape, but the man in the small town soon finds his credit t'ed up in his used cars."

Three of the subjects planned for discussion discounts, exclusive representation, and freight rates were eliminated, the dealers themselves being unable to agree on discounts. A formal statement given out by General Manager Reeves after the meeting follows:

"Representatives of the N. A. C. C. and the N. A. D. A. held an all-day session at the Detroit Athletic Club today and considered such items as yearly contracts, used cars, parts, stocks, advertising and service to the public. Contracts were considered from the viewpoint of clauses that would strengthen the dealer with his banker and his customer on the problem of used cars.

"It was agreed that a general investigation should be made into the used-car situation by the national organizations. Sectional advertising for the benefit of the dealers, a closer and more frequent survey of parts stocks and a broadening of service plans for all users of cars and trucks were deemed necessary for the dealers' success. To-day's suggestions with additional information to be obtained after consideration by manufacturers and dealers, will be the subject of another meeting of the committees to be held in Detroit next month."

W. E. Metzger to Handle Wills Sales in Detroit

DETROIT, May 9—W. E. Metzger, a pioneer automobile man, will take over the Detroit distribution of the Wills Sainte-Claire with a salesroom on the ground floor of the Ford Building. He expects to have a car on display in two weeks.

Mr. Metzger graduated from a bicycle agency and in 1899 handled the first electric automobile in Detroit. In 1890 he took over the Oldsmobile and helped organize the Cadillac Motor Car Co. In 1902 and 1908 he was with B. F. Everett and Walter E. Flanders, who organized a company which brought out the E M F car and later formed the Metzger Motor Car Co. In 1909 he built the Everett car and merged with Maxwell. In 1912 he was vice president of the Columbia Motor Co, and an officer and director of other companies.

TRACTOR DISPOSAL HITS HOLT

PEORIA, ILL., May 7—As a result of the turning over by the Government to state highway commissioners of a large number of 10-ton Holt caterpillar tractors, the Holt company has closed its factory temporarily to permit of readjustment of conditions. The factory force and a part of the office staff are affected.

A. E. A. CONVENTION JULY 4

CHICAGO, May 7—The date of the convention of the Automotive Equipment Association, at Mackinac Island, has been changed from the week beginning June 20 to the week beginning July 4. Hotel arrangements were responsible for the change.

White Motor Makes Change in Officers

Windsor T. White Retires as President and Is Succeeded by Walter C. White

CLEVELAND, May 9—The first shift in the personnel of officers of The White Co. since it was organized was announced at the close of the annual meeting of directors, which followed the stockholders' meeting. The change in officers marks the passing of control of the corporation from the hands of older men, who largely have been responsible for the upbuilding of the corporation. Their places will be taken by trained young men, who have come up from the ranks. The changes follow:

Windsor T. White, resigned as president of the company, and is succeeded by his brother, Walter C. White. W. T. White was elected chairman of the board of directors.

A. R. Warner, secretary, resigned, and is succeeded by T. R. Dahl, who has been assistant secretary. Warner asked to be relieved from active duty, but he was re-elected to the board of directors.

E. W. Hulet, who has had charge of production, presented his resignation, but he was asked to remain with the company in an advisory capacity and consented.

All three of the officials have been connected with The White Co. for seventeen years or more, and while the active management will hereafter rest upon the shoulders of more youthful men, the ones who have been on the job for so long will be available for advice and counsel. The new president has for some time been senior vice-president, and for years has been active in the management of the corporation.

Teagle Becomes Director

One of the notable additions to the Board of Directors was Walter C. Teagle, president of the Standard Oil Co. of New Jersey. Teagle was born here and he is still interested in many Cleveland business and financial institutions. William G. Mather, president of the Cleveland Cliffe Irons Co., one of the leading business men of Cleveland, also was elected a director. Other directors elected are: J. R. Nutt, president of the Union Commerce Bank; Warren S. Hayden, Otto Miller, Homer H. Johnson, Albert R. Warner, Windsor T. White, Walter C. White and Thomas H. White, all of Cleveland; E. R. Tinker of New York City, and Philemon Dickinson of Philadelphia.

The retiring president told the stockholders and the directors that in his opinion the low point in business, not only in the automobile industry, but in other lines, had been passed and that from now on business would continue on the up-grade. Evidence of this was manifested in the report of the company. The regular quarterly dividend of $1 a share was declared.

March of Industry Continues Steady

M. A. M. A. Analysis for April shows Unbroken Gains—July Slump Doubted

NEW YORK, May 9—A month's sustained and unbroken progress in the onward march of the automotive industry is reflected in the May analysis of conditions made public to-day by the Motor and Accessory Manufacturers Association.

"The gratifying betterment of fundamental factors noted in last month's survey is increasingly manifest in the first-hand reports and authoritative financial data consolidated in the summary for the month of April," comments M. L. Heminway, general manager of the association.

"Payments for the last month have been better than for the three months prior," says the report.

"More firms are paying their current accounts in full on due date, and an increasing number are paying a larger proportion of their notes as they fall due, quite a number paying in full.

"Releases on old orders show a decided improvement. Many of the car and truck manufacturers are placing orders for new materials. Virtually all the car manufacturers are now showing signs of life, and this applies to the manufacturers of trucks and tractors to a somewhat lesser degree.

"Quite a number of vehicle manufacturers are operating their plants at full time or nearly so.

"Labor conditions in the automotive industry seem to be causing comparatively little trouble. There is a marked increase in labor efficiency following the readjustment period."

These statements loom up conspicuously in the chart of automotive trends plotted with the greatest possible precision by the credit and financial executives of the principal manufacturers making parts, units, and accessories for the passenger car and truck builders. Close to 400 of these parts-purveyors are affiliated with the association.

Group Meetings Show Trends

Through monthly group meetings for the interchange of credit information and the pooling of experiences and viewpoints, these unit and equipment makers are able to diagnose conditions in an impartial and scientific manner. No attempt is made to cloak unpleasant facts. The parts makers must face the conditions as they are. Their verdict is therefore based on evidence, not on expectation.

During the last week in April five groups of the association met to discuss business and financial conditions generally and the credit entitlements of the makers of motor vehicles. One group met in New York, the others in Chicago, Detroit and Cleveland.

The information on business conditions brought out in the five groups showed little variation. Without exception every significant indication was constructive. Some members, to be sure, insisted that the present improvement in business is only a spurt which will be followed by a decided slump after July 1. This, however, was distinctly a minority report, in no way sustained by the preponderant weight of the evidence. The majority opinion seems to be that the improvement has been so gradual and consistent that it presages a continued increase of business along conservative lines.

Feeling Decidedly Better

"Altogether," says the report, in recapitulation, "there is a decidedly better feeling among our members. Collections are better and money required from banks seems to be somewhat easier. Many plants are resuming operations on a larger scale than heretofore, and the condition of extreme depression has certainly changed for the better."

Makers of automotive accessories and the smaller replacement parts report an unusually large volume of business from dealers and jobbers.

A first-hand up-to-the-minute report on automotive business conditions on the Pacific coast was telegraphed to the association's headquarters by Ezra W. Clark, advertising manager of the Clark Equipment Co., Buchanan, Mich., who is making a speaking tour across the continent, addressing local dealers' organizations and chambers of commerce. He is also placing on exhibition his oil paintings on "The Spirit of Transportation" by twelve of the leading artists of America who portrayed on canvas their "conceptions of the dynamic force of civilization—transportation."

"Business conditions on the Pacific coast show decided improvement," telegraphed Clark.

"New registrations are greater than last year, showing more sales. Dealers' associations strength in adversity has shown need of solidarity and co-operation. Organizations are putting on real sales pressure.

"San Francisco is now holding wonderful open road week. Present stocks of cars will be exhausted in two weeks.

"Many better known cars are now unable to make floor deliveries.

"Due to prohibition California has received splendid price for grape crop, many new vineyards being planted.

"Good demand for heavy trucks for highway construction and light trucks for agricultural use."

OVERLAND RISES 71 PER CENT

TOLEDO, May 9—The Willys-Overland Co. announces that, taking sales since the first week of March as a starting point, business has increased 71 per cent. The retail sales for the second week showed an increase throughout the country of 17 per cent over the first week, the third week an increase of 41 per cent, the fourth week a decrease of 25 per cent, the fifth week an increase of 60 per cent, and the sixth week an increase of 71 per cent.

Industry Reemployed 31,986 Men in April

Leathers, Textiles and Liquors Also Improve Positions—Steel Reports Declines

WASHINGTON, May 7—While the finance committee of the Senate is considering the imposition of additional taxes on the already overburdened automotive industry, the Department of Labor has made public a summary of employment conditions showing that manufacturers of motor vehicles and allied lines are virtually sustaining the entire industrial structure at a time when other lines of business are in deep depression.

The labor department report shows that there was an increase in unemployment in 28 out of 53 industrial centers east of the Mississippi in the month of April. Virtually the only places in which employment increased were centers of automotive activity. The chief gains were noted in Detroit, Chicago and Toledo. Detroit led all other cities in the percentage of increase with a gain of 25.9 per cent. The industry as a whole added 31,986 workers to its payrolls in the month, an increase of 22.3 per cent over March.

The only industries which improved their position in April were automobiles, leather, textiles and liquors. These four took on 42,630 workers, but approximately 75 per cent of this gain was in automobile and allied plants.

The report shows that in most places where the number of men out of work was reduced, automobile and allied lines relieved unemployment through gradual increases in their forces. While there was a sharp decline in the volume of iron and steel business, a good share of what was obtained came from the automotive industry.

DISCOUNT RATES CHANGED

WASHINGTON, May 7—Reports received by the Federal Reserve Board indicate a steady and sustained improvement in credit conditions. Large increases in reserves show that there has been a heavy liquidation of frozen credits and all the reserve banks are expected to announce a lowering of their rediscount rates in the near future. This action already has been taken by the banks in Boston, New York, Atlanta and Chicago. Boston cut its rate on commercial paper to 6 per cent, New York followed with a reduction from 7 per cent to 6½ per cent, Atlanta reduced the rate from 7 per cent to 6 per cent, and Chicago from 7 per cent to 6½ per cent.

HARVESTER PAYS BONUS

SPRINGFIELD, OHIO, May 7—More than 500 employees of the Springfield works of the International Harvester Co. have received extra compensation and stock certificates under the policy of the company announced last year.

Form Moline Engine as R. & V. Subsidiary

Company Will Be Expanded to $15,000,000 Annual Production—New Officers Named

EAST MOLINE, ILL., May 7—The Moline Engine Co. formal organization is being completed and in addition to its established business of producing poppet-valve engines, the company will manufacture Knight engines for the R. & V. Motor Co. The Root & Van Dervoort Engineering Co. will hold all capital stock of the engine concern and thus becomes merely a holding corporation for the R. & V. industries. The automobile manufacturing plant has already been separated and organized as the R. & V. Motor Co.

Expansion of the Moline Engine Co. is announced and annual production valued up to $15,000,000 is scheduled.

Directors of the three R. & V. unit organizations recently elected the following officers: President, H. A. Holder; vice-president, G. A. Shallberg; secretary-treasurer, S. G. Smith, and assistant secretary-treasurer, G. L. Walker. C. H. Van Dervoort was elected a vice-president of the motor company and will direct its sales. In addition to these officers the directors are O. J. Root, Rufus Walker, Jr., R. S. Hawes, J. W. Reinholdt, S. A. Mitchell and D. W. Gurnett.

With the announcement of the organization plans, formal confirmation was given of the sale of 74 acres and 15 manufacturing and administrative buildings of the concern to the Troy Laundry Machine Co. of Chicago, which, beginning Sept. 1 will move its plant to this city. This sale, it is announced, will not curtail activities of the R. & V. organizations but centralize their work.

Denial has been made to rumors that the Continental Motors Corp. is negotiating for purchase of the engine division of the organization.

FALLS MOTORS AT CAPACITY

MILWAUKEE, May 9—The Falls Motor Co., Sheboygan Falls, Wis., a large manufacturer of motors for passenger cars, trucks and tractors, is now operating its works at full capacity to fill its orders. Some departments are working overtime and the remainder on full time. In the last few months the company has completed the installation of a new forge shop, heat treating department and a new testing shop, as well as a complete first aid hospital.

SAMSON OFFICERS CHANGE

JANESVILLE, WIS., May 9—J. A. Craig, president of the Samson Tractor Co., division of General Motors, has announced three changes in departmental personnel. M. J. Gregory, foundry superintendent, is temporarily assigned to the Saginaw Products Co., Saginaw, Mich., but will return to Janesville when the new foundry unit of the Samson plant is completed in about two months. J. P. Little, assistant factory manager, is transferred to the Chevrolet works at Flint, Mich. D. W. Robertson, advertising manager, has been granted leave of absence for the summer months to enable him to rest and recuperate at Northern Wisconsin lakes. President Craig recently returned from a trip to the Pacific Coast for recreation. While in the West he spent some time at the Samson company's Pacific Coast works in Stockton, Cal. In addition to tractors, the Stockton plant is putting a new design of Samson disk plow into production.

Post and Whitney Form New Tractor Company

CLEVELAND, May 9—The Post Tractor Co. of this city and the Whitney Tractor Co. of Upper Sandusky, Ohio, have been consolidated under the name of the Post-Whitney Co. This company which is capitalized at $10,000,000, is headed by C. P. Casatt of this city. The other officers are: Vice-president, A. B. Whitney, Upper Sandusky; treasurer, C. B. Post, New London, Ohio; secretary, F. R. LePage, Cleveland. The officers, with Ralph Blue and A. H. Weiblem of Cleveland, constitute the board of directors.

The company will maintain the plant at Cleveland where the Post tractor will be manufactured and the Whitney plant in Upper Sandusky where the Whitney tractor is being built. An announcement is expected soon regarding the purchase of an engine plant in which engines and transmissions will be built. The Whitney tractor has been manufactured for several years and is of two-cylinder, four-wheel, two-plow size. The Post tractor has been in process of development for some time and is now being put into production. It has both a front and rear drive and is of three-plow size.

GASOLINE DOWN TO 23.4 CENTS

NEW YORK, May 7—The average price of gasoline in 30 large cities of the country is now 23.4 cents a gallon, wholesale, compared with 29.3 cents at the beginning of the year, a decline of 5.9 or 21 per cent. The sharpest declines have been in cities of the Mid-Continent district. The price in Dallas, Tex., has dropped from 31 cents to 19 cents since Jan. 1. The second largest decline was a drop of 11 cents in Tulsa, Okla. Houston, Tex., shows a drop of 10 cents a gallon and Kansas City 9.5 cents a gallon.

MOON GAINS 27 PER CENT

ST. LOUIS, May 7—The Moon Motor Car Co. announces that its domestic business is running 27 per cent ahead of domestic business for the same period last year. This period covers the first four months. Export business practically has ceased, but notwithstanding this fact, the total gross sales for January, February, March and April exceeded sales for the first four months of last year.

American Chain Buys Four Bumper Patents

Licenses Are Granted to Leading Makers to Avoid Confusion in Trade

BRIDGEPORT, CONN., May 9—The American Chain Co. has entered the bumper field and has acquired ownership or control of the Hoover and Fageol patents which cover bumpers of the spring steel type, as well as the Pancoast and Grotenhuis patents of the Biflex type, covering bumpers having between the ends of the bumper bar a widened impact portion in front of the radiator.

Licenses under all three groups of patents have been granted to the following companies: C. G. Spring Bumper Co., succeeding U. S. Auto Bumper Co. and Kalamazoo Spring & Axle Co., Chicago; L. P. Halladay Co., Streator, Ill., Biflex Products Co., Waukegan, Ill., New Era Spring & Specialty Co., Grand Rapids, Mich., and Gemco Mfg. Co., Milwaukee.

These companies are authorized to use the inventions covered by these patents in bumpers made and sold by them. The American Chain Co., while it is said to intend energetically to enforce its rights against infringers, has adopted a liberal policy of granting licenses generally to responsible manufacturers upon reasonable terms.

Had it been decided to exclude others from the use of the inventions in question the results to the industry might, in view of the importance of the patents involved, have been of a serious nature, creating much confusion in the bumper trade.

HARVESTER DEFERS PLANT

FORT WAYNE, IND., May 9—All further construction work on the big truck plant which is to be erected by the International Harvester Co. in this city has been postponed for the time being. An extension of time in which to start actual construction operations has been granted to the company by the Greater Fort Wayne Development Co., which holds the contract with the Harvester company and which was organized for the purpose of building homes in which to house the workers at the plant. The development company's office will be closed until such time as the Harvester company starts operations. Business conditions are the reason for this postponement of the work. It is believed that it may be a year before the work on the construction of the plant is resumed.

PETROLEUM ERECTS FIRST UNIT

ROCKFORD, ILL., May 7—The first unit of the Petroleum Motors Corp., which will make kerosene burning engines, will be started in a few days and the production schedule started in 60 days. An output of 10 to 12 engines a week is expected.

Bank Finds Prices Holding Up Buying

Republic Bank of Chicago Predicts Automobile Reductions as Business Declines

CHICAGO, May 9—The indisposition to buy in all commodity lines is still prompted by the lack of confidence in present price levels and by the desire to buy only at bottom prices, is the finding of the National Bank of the Republic of Chicago in its résumé of April business throughout the country. At the same time it declares that further reductions in the price of automobiles is dependent upon the continuance of the present buying movement of motor cars. Prices will be lowered further, it predicts, as soon as it is seen that a stimulant for sales is needed.

"The steady improvement in the automobile industry," it says, "reflects in no small degree the demand for cars by that section of the public designated as the 'fixed income class' and by that class whose wages still leave an appreciable margin of income over necessary expenses. While shipments of automobiles in March were still 58 per cent below the volume of the same month last year, many dealers expect sales in the second quarter to approximate 75 per cent of the same quarter of 1920, which was a record. While this goal may be attained it is believed that the pace cannot be continued throughout the year, as in times past, but that manufacturing as well as selling will revert temporarily to a seasonal basis.

"It is apparent that the manufacturers themselves distrust the permanence of the present improvement, as they are keeping output closely in conformity with incoming orders, and in many cases are deliberately adhering to a fixed schedule much under the volume of new business. This is done to avoid any possible surplus, should the demand fall off, as well as to keep the demand far enough in advance of output to obviate the necessity of further price reductions which might again unsettle the industry. At the same time the matter of price reductions is being kept in reserve as a possible sales stimulant should the present buying movement wane."

April Business Gains in Texas Territory

FORT WORTH, TEX., May 9—The automobile business in the Southwest has started on the up-grade again, according to dealers in all sections. April sales far exceed those of March and May is beginning as though it will surpass April. Comments by dealers follow:

J. B. Mikesell of Houston, whose agency extends over thirty-nine south Texas counties, declares that the dealer in standard cars is moving his automobiles rapidly and is prospering again.

Plenty of cars are being sold in Austin, says Ben M. Barker of the firm of Barker & Co. Business there, he says, is staging a come-back and the revival is taking like wild-fire.

George K. Marshall of Galveston, R. S. Carter of Galveston, William Morriss of Dallas and L. E. Askew of Dallas also announce a general sales gain in their respective sections and a bright outlook for the summer months.

The settling of the weather in the Southwest, which until now has been wet and cold, has stimulated business.

Higher Priced Trucks Lead in New Business

CHICAGO, May 8—Reports reaching the Motor Truck Mfrs. Assn. indicate that the truck industry is staging a come-back, though it may not be as noticeable as the return of the automobile. The majority of manufacturers report better business and show a more optimistic spirit than has been evidenced for many months. Conditions are somewhat spotty, but as a whole they are good considering what they have been for months past, and give every ground for the foundation of optimism.

While the preponderance of interest on the part of buyers centers in the higher priced, heavy duty trucks, there is movement in the others. Truck interest is more or less of a barometer for conditions as they prevail in general business lines and the fact that the higher priced trucks are the first to be called into service points to a resumption of activities in the larger businesses which, naturally, are the first to feel the effect of improved conditions. Users of the smaller trucks whose activities depend to a great extent on the business transacted by the larger owners will follow into the market in gradually increasing numbers.

One manufacturer of the higher priced trucks has stated that his business for the past month was better than at any time for more than a year.

SOUTH TO EXTEND ROAD-WORK

ATLANTA, May 6—Project agreements for the construction of highways in the South in the six States comprising this district with headquarters at Montgomery, Ala., totaling $34,831,213, have been executed, according to a report just issued. Georgia leads the district in the amount of money already obtained or to be obtained for highway work on project agreements already approved, with $5,563,128.24 from the Federal government. Georgia will spend $12,214,791.09 in projects that have already been approved. Of the total amount for the six States the Federal government contributes $16,259,710.98.

STIFFENS THEFT PENALTY

WASHINGTON, May 6—Senator Nelson of Minnesota has introduced a bill to make the moving of a stolen automobile from one state to another punishable by five years imprisonment and $5,000 fine.

California Business Waits Price Action

Present Owners Found Buying to Get Full Value on Used Cars —Shows Help Selling

SACRAMENTO, CAL., May 10—The automobile trade in northern California is recovering from the reaction which followed the first return of normal business conditions. After the first impulse on the part of buyers to secure cars, there followed a lull which made dealers somewhat apprehensive, but active advertising and a following up of sales prospects has brought about what appears to be a steady buying activity.

Many smaller cities of the district have announced automobile shows, and these have been reported as having a very healthy influence on the buying public. In nearly every instance dealers of these towns report the effort and expense attending these exhibits well worth while.

Heavy damage to fruit crops through frost, and injury to the grain crops through north winds made the sales companies fearful of a decided slump, but this has not put in an appearance. The situation appears not to be so much one of a lack of money as a belief that automobiles will suffer a further drop in price. The announcement of the Jordan cut, however, did not affect the market here noticeably and the demand for smaller cars appears particularly good.

Another proof of the waiting attitude of the buying public is the fact that the bulk of the sales are to owners of cars who are turning in their old automobiles. These recognize the value of their cars will go down with any possible cut in the price of new cars and that it makes little difference to them when they purchase, so far as a change in price is concerned. The used car market is fairly good notwithstanding the resultant flood.

PETERSON OPENS IN MEXICO

LOS ANGELES, May 6.—The Peterson Corp., which handles rebuilt cars exclusively, has extended its field to include Mexico. Its first branch in that country was recently opened at Guadalajara, the second city of the republic, and announces that additional branches will be opened at Mexico City, Puebla, San Luis Potosi, Monterey, Tampico and Merida, thus covering the most important cities of Mexico.

A. S. M. E. TO INSPECT PLANTS

CHICAGO, May 6—One of the industrial plants which will be inspected by the delegates to the spring meeting of the American Society of Mechanical Engineers which will be held here May 23 to 26, will be the McCormick and Deering factories of the International Harvester Co. The South Chicago works of the Illinois Steel Co. also will be inspected.

British Car Imports Show Gain in April

Parts Importations Fall Off Heavily But Tires Increase—Exports Active

LONDON, April 15 (By Mail)—A notable increase in the number of imported motor cars, commercial vehicles and chassis is a feature of the figures for March contained in the Board of Trade returns of imports and exports. The total is 1153 compared with 752 in February. The corresponding value has risen by $1,600,000 for March.

A drop is apparent in the value of imported parts, other than tires, the figure being $873,450 as against $2,335,560 in February. On the other hand there is a slight increase in the value of imported tires, the figure for March being $1,340,000, against $1,066,320 in February.

Little change characterized the volume of British export auto trade in March. The total export of cars and trucks was small, the March figure being 407, a drop of 5 on the February total of 412. The value of the export of cars and trucks shows an increase, being $1,825,500 compared with $1,765,220 for February. The value of exported parts increased to $668,350 compared with $552,090 in February. The value of exported tires rose from $837,365 in February to $1,222,000 in March.

Imported chassis in March had an average value of $1,450 as against $4,810 per British chassis exported.

The foregoing exchange rates are taken as at par, $5 to the £1.

BRITISH REGISTRATION HEAVY

LONDON, April 8 (By Mail)—According to a just issued return of the Ministry of Transport, Britain had registered on March 10 under the new motor taxation scheme, which came into effect on Jan. 1, 281,600 motorcycles, 202,000 cars, 102,500 taxi-cabs and passenger coaches (including autobuses and charabancs), and 208,400 road trucks of all kinds. *Trucks are paying* 51.3 *per cent of British motor taxation.* The estimated expenditure on British roads this years is $225,000,000, but the outlay in normal times is expected not to exceed 50 million dollars yearly.

BRITISH MOTORCYCLE CUT

LONDON, April 15 (By Mail)—The Triumph Cycle Co., Inc., Coventry, has revised the prices of its motorcycles and motorcycle sidecar combinations, the reduction ranging from $25 to $75.

MEXICO GETS FORD TRAINLOAD

LAREDO, TEX., May 7—A solid trainload of Ford automobiles passed through here this week consigned to Ford dealers in Mexico. The cars were crossed into Mexico at this point without delay and, notwithstanding the motive power shortage in that country, the train was sent South as soon as it reached the other side of the border. It is stated that this is the first of several similar shipments that are to be made soon. Many used cars are also being shipped to Mexico. Dealers in Laredo, San Antonio, Eagle Pass, El Paso and other towns on and near the border are flooded with orders for used cars from Mexico, it is said.

South American Feeling Unfriendly, Says Banker

YOUNGSTOWN, OHIO, May 9—W. A. Beecher, vice-president of the Mahoning National Bank and director of the Powell Pressed Steel Co., Youngstown, who has just returned from a trip through Brazil, Argentina, Uruguay, Chile and Peru with a party of bankers, states that the feeling of the people of South America is not altogether friendly toward the United States.

Organized propaganda, inspired by Germany, it is believed, is being directed against American business in South America, he states, and furthermore the business methods during the war, principally the failure to deliver goods according to contract are responsible for the unfriendliness on the part of business interests.

"Conditions in South America are somewhat depressed," says Beecher, "largly due to the depreciation of the English pound on which they base their currency. Large quantities of goods are tied up in the wharves and warehouses of South American ports, because they do not have the money to pay for them. In Buenos Aires alone 4000 automobiles are boxed up. The feeling against America is partly our fault and part of it is propaganda. When we began to fail to make delivery of goods along during the war due to our products going elsewhere and the effect was readily felt. Now the South Amercans are inclined to resent it."

WOULD CLOSE OUT AUSTIN

(By Cable to AUTOMOTIVE INDUSTRIES)

LONDON, May 7—Following the appointment of a receiver for the Austin Motor Co. a petition for the compulsory winding up of the company's affairs was presented by a creditor and ordered heard by the court. The law provides that persons interested must be represented for or against the petition and that until arguments are heard the company's assets and business must not be interfered with.

SMALL TIRES LEAD IN JAPAN

WASHINGTON, May 7—As 96 per cent of the total number of automobiles imported into Japan are of American make, three-inch tires are universally used. The ordinary clincher type, writes Trade Commissioner Abbott, is the most popular, and the sizes in common use are 30 x 3½, 32 x 3½, 32 x 4, 33 x 4, and 34 x 4½ in.

Light Cars Leading in British Markets

Many Makers Rushed to Meet Orders—Opinion Differs on Price Cuts

LONDON, April 27 (By Mail)—Some extraordinary contrasts are apparent in the demands for British cars. While one or two plants now have difficulty in keeping pace with orders, others are practically closed down. In Coventry, Humbers are a month behind, despite working at full pressure, Singers and Standards are also very busy and Rovers are trying hard to work up again to full production on their 8 hp. air-cooled runabout; Calthorpes in Birmingham are instituting a night shift and Wolseleys are fairly well occupied, though not operating full time in all departments.

On the other hand, Daimlers have all but closed down, and though a labor dispute is partly accountable, continued slackness is primarily responsible and has caused a lockout of the staff because the latter were not allowed by their union to work on a new basis of pay which the majority had found acceptable.

The liveliness in some quarters is not due in all cases to price reductions. Humbers, for instance, have not receded a cent, in fact one model with recent improvements has increased nearly $300. Singers and Calthorpes have made severe cuts, however, and seem to have benefited by a rush of orders on that account.

Dealers especially maintain that too much has been made of mere reduction in price and not enough of better value. The public, it would seem, takes it that a big cut means either that a car has been priced at an unreasonable level hitherto, or that it is not popular enough.

The plants which are doing best are those which are turning out good light cars, small four-seaters in particular, with a presentable finish and economical to run. That a comparatively high price is not a bar, providing the value is there, is exemplified by the demand for the improved and very slightly enlarged 10 hp. Humber. Of its type it is the most expensive, selling freely at £700 (say $3500) for the four-seater. It is not a matter of stocking up dealers, for the latter are in many cases giving supplementary contracts.

Guarantees Hold Up Cuts

The price guarantee system introduced early in the year has placed some firms in a quandary. While they are believing that a reduction now would induce more orders, they dare not make one owing to their commitments under the guarantee, which does not expire until July 1 at the earliest.

The whole position is very unequal. Some firms are doing well at old prices, some at lower prices; the remainder badly on either basis. The only semblance of uniformity is that nearly all those giving good value in light cars of repute are not complaining.

Congress Orders Army Truck Sale

Makes Obligatory Immediate Disposal

Provision for Transfer to Roads Departments Killed—Fixes Excess at 12,000

WASHINGTON, May 11—An amendment of the Army bill which passed the House yesterday makes it obligatory on the Secretary of War to sell immediately at public auction or private sale all surplus motor trucks and passenger automobiles now in the possession of the War Department. The provision in the present law authorizing the transfer of motor equipment to the Bureau of Public Roads was eliminated in the Army Appropriation bill.

The surplus is approximately 10,000 trucks and 2000 passenger cars.

Under the terms of the amendment, the Secretary of War has no choice but to sell all the motor vehicles on hand beyond those necessary for an army of 150,000 men. Auction sales of unserviceable automobiles and trucks have been held at camps by the Motor Transport Corps for the past two months. There will be another to-morrow at South Amboy, N. J., at which several hundred trucks and light delivery cars will be sold.

The introduction of this amendment by Representative Anthony of Kansas precipitated a debate as to the methods employed by the War Department in disposing of surplus motorized equipment. According to Representative MacGregor of New York, sponsor of the drastic requirement of sales, the number of army motor vehicles up to and including April 23, 1921, was 63,429, of which 50,321 were serviceable and 13,108 were unserviceable. Of this total, 53,423 were in closed storage, while 10,006 were in open storage.

With the proposed reductions in effect, the authorized retention of motor vehicles for the army of 150,000 men would be 4245 passenger vehicles, 19,652 trucks, 4218 trailers, 5058 motorcycles, 2048 ambulances and 1328 vehicles of special designs, making a total of 36,541 motor vehicles for the regular army.

Senate Gives Mellon Anti-Dumping Power

WASHINGTON, May 12—Senator Ball of Delaware informed AUTOMOTIVE INDUSTRIES to-day that the anti-dumping bill, which passed the Senate yesterday, authorizing the Secretary of the Treasury to levy customs duties in cases where an investigation disclosed unfair competition, would protect American dealers against reimportation of surplus war supplies sold abroad by the Federal government. The automotive industry had hoped that a clause would be inserted in the bill covering this subject specifically, as European speculators contemplate throwing enormous quantities of motor vehicles and equipment on the American market.

Because of drastic changes made in the Senate in the anti-dumping bill, it is expected a bitter fight will follow when it goes to conference in the House. This may result in a disagreement and throw the bill back for passage through both houses.

Formation in New York of an import organization which proposes to sell $3,000,000 worth of automobile equipment purchased from the Slough Trading Co. of England, is expected to stir automobile manufacturers and dealers to such an extent that they will attempt to convince Secretary of the Treasury Mellon that an inquiry into this competition is essential for protection of American industry. The finding of investigators would determine the amount of duty which Mellon could levy to equalize domesic prices and quotations.

If the Senate and House conferees fail to agree on the bill as it passed the Senate, opportunity would be given automotive organizations to express their views on the subject if they cared to avail themselves of the chance.

Mixter Is Invited to Head Pierce Arrow

NEW YORK, May 11—George W. Mixter, who has represented G. W. Goethals & Co., Inc., in the management of the Pierce-Arrow Motor Car Co. since 1919, has been invited by the directors of the Buffalo company to become the president of Pierce-Arrow, and it is understood that he will sever his connection with Goethals to accept.

Goethals & Co. were employed by the Pierce-Arrow company to assist in bringing the plant to a peace-time basis and also to aid in reviving its line of cars and trucks. This work has been accomplished and a new line of vehicles, both passenger and commercial, has been placed in production.

Mixter has been in active charge of the plant since that time and his management has been entirely successful.

MOORE PROMOTERS ON TRIAL

ST. LOUIS, May 11—Six promoters of the Moore Motor Vehicle Co. of Danville, Ill., went on trial in Federal Court here to-day on charges of using the mails to defraud. They are accused of having sold stock amounting to $1,500,000 without return to the purchasers.

Tire Companies Cut to New Price Level

Goodyear Reduction Ranges 12 to 15.8 Per Cent—Kelly Decrease Largest

NEW YORK, May 11—With the announcement of a price cut, ranging from 12 to 15.8 per cent on tires by the Goodyear Tire & Rubber Co., practically all of the larger Akron companies have revised their lists.

Firestone, as part of its price revision plan, will produce a new 30 x 3½ smooth tread tire, to sell at $13.95. The company declares this to be the lowest priced of any standard tire of that size on the market. Cord prices are cut 12 per cent; fabrics, 17 per cent, and tubes, 20 per cent.

Miller has cut cords 12½ per cent; fabrics, 17½ per cent, and tubes, 20 per cent. The new prices reduce the 30 x 3 fabric tire from $17.25 to $14, and the 30 x 3½ cord, from $32 to $24.

The 12 per cent cut by Goodyear is on cord tire prices. A 15 per cent cut is made on the general run of fabrics, with a 15.8 per cent reduction on some sizes of fabrics. Tube prices have been reduced 20 per cent.

United States Rubber Co. has reduced prices from 11 to 20 per cent; the minimum cut on cord tires and the maximum on plain tread tires and gray and red tubes. A 15 per cent reduction is made on Usco treads and a 17½ per cent cut on knobby and chain treads.

Kelly-Springfield Tire Co. makes a straight 20 per cent reduction on all pneumatic tires except Ford sizes, which are cut 22 per cent. Tubes are reduced 30 per cent.

Fisk Rubber Co. has reduced prices from 12½ to 20 per cent.

Lee Rubber & Tire Co. reduced 20 per cent in the price of cord and fabric tires and 15 per cent in puncture proof tires.

Keystone Tire & Rubber Co. has made a straight 20 per cent reduction.

Thermoid Rubber Co. has made a price cut on all Ford sizes of 28 per cent; on 4½-in. sizes, 23 per cent, and on all other sizes, 20 per cent.

Erie Tire President Guilty of Embezzlement

TOLEDO, May 10—Peter F. Wills, president of the Erie Tire & Rubber Co., was found guilty of embezzlement of $29,793 of his company's property by a jury in common pleas court at Sandusky last Friday night. The jury was out twelve hours. Sentence was withheld for a few days.

Square Deal on Tax Aim of Industry

Highway Committee Approves Principles of Townsend Bill—Push Advertising Plans

(*Continued from page* 1033)

colleges and a similar number of cards bearing the statement of President Harding, declaring the motor vehicle a necessity, will be sent out to dealers and garage men for prominent display where it will attract the attention of the general public.

The Highway Committee met Tuesday, when the principles of the Townsend bill were approved, and Roy D. Chapin, chairman of the committee, and George M. Graham were named to go to Washington and present the views of the chamber. More vigorous efforts in the educational campaign for better roadways were decided upon through the agency of schools and colleges and by personal and printed appeal to the general public.

The Truck Committee also met Tuesday and spent much time in consideration of the anti-dumping bill pending before Congress. It was said strong pressure would be brought to bear to insure Congressional action against the reimportation of trucks. The plan for co-operation with the railways to secure the short haul business for motor trucks was given much consideration and arrangements made for presentation of the truck manufacturers' plan to the Interstate Commerce Commission, with the feeling prevailing that the railways now are in a receptive mood and that definite agreement on a policy for division of this business would result.

Reeves Talks Advertising

With the idea of stimulating closer cooperation between the advertising managers of the automobile and truck companies and the National Automobile Chamber of Commerce a meeting of the advertising men was held Friday, presided over by Alfred Reeves, manager of the chamber. Reeves emphasized the point that service and advertising now are the vital factors in the merchandising of motor vehicle and declared the time had come when the advertising manager must be lifted out of the rut and given his proper place in the administrative effort looking to sales promotion. He pointed out some evils that exist and cautioned the ad men against repetition. In a critical time like this, said Reeves, every man must be unusually careful to see that every word that goes out as advertising copy carries a real message to the consumer.

H. R. Hyman, advertising manager of Cole Motor Car Co., read a paper on "New Forces in Automobile Advertising." Hyman took his fellows to task for some of the crude methods that have marked their efforts and laid stress on the value of illustrated advertising of the right sort. He deplored the tendency toward freak pictures and urged more thought and less anatomy in illustrations. Efforts to convince the public that the automobile is a necessity and to educate the owner to its proper use were urged by Hyman, who declared the industry was struggling with a buyers' market and if the product was to be merchandised properly it must be through advertising. The dealer, he said, is demanding co-operation of the factory in his effort to get to the consumer and urged that the advertising manager now has the big opportunity to show his real merit.

Dart Presents Paper

H. G. Dart, advertising manager of Paige Detroit Motor Car Co., read a comprehensive paper on "General Advertising Plans That We Have Found Helpful," in which he told of experiences in his own factory with especial reference to the mistakes and the benefits of the lessons learned. He pointed to many instances where beneficial results in sales promotion were traceable directly to efforts of the advertising department and urged more careful thought and study in the preparation of material that was designed to appeal to the prospective purchaser.

General discussion followed the reading of the papers in which many joined and in which the good and bad effects of various efforts were threshed out. Decision to affiliate with the National Automobile Chamber of Commerce as an advertising managers branch was reached and assurance was given Reeves of full co-operation of the ad men.

N.A.C.C. Committeemen to Confer in Washington

NEW YORK, May 10—The representatives of the National Automobile Chamber of Commerce who will appear before the Senate finance committee in opposition to increased Federal taxes will hold preliminary conferences at Washington Friday, Saturday and Sunday in preparation for the argument next Monday. The hearing will be given specifically on the question of excise taxes and the burden of the argument will be against discriminatory imposts.

The National Automobile Dealers' Association also has asked for a hearing on the excise section of the revenue law and this also may be granted Monday, but at a different hour. The course of the Motor and Accessory Manufacturers' Association and the Rubber Association of America in relation to appearances before the finance committee has not been definitely determined, but M. L. Heminway, general manager of the M. A. M. A. will appear with the N. A. C. C. committee unless his association is granted a separate hearing.

The N. A. C. C. decided that inasmuch as it was not the chief proponent of the sales tax, it would not make an appearance this week with the industries which are advocating that form of tax.

Anti-Dumping Action Unfair, Say French

Compelled to Take Thousands of Cars After Armistice—Would Turn Some Back

(*Continued from page* 1033)

over by the French Government. Most of the pneumatics were used by the French army or sold privately, but the solids remain, and are to be thrown on the market, after having stood in the open for more than two years.

It will be a difficult matter to dispose of more than a fraction of these spare parts in European countries, for the stocks are out of proportion to the number of vehicles in service here. The purchasers declare that it is their intention to sell in big lots, as far as possible, and to dispose of this material in America if purchasers can be found. It is thought that these supplies will interest American jobbers, manufacturers, and big truckers. A thoroughly commercial sales organization is being gotten together.

French opinion fails to understand why America should protest against the shipment of American army automobiles, trucks and parts to the United States. One leader of the French industry declared a few days ago:

"We were obliged to take 80,000 American automobiles after the Armistice. After the thousands we had purchased for our own army from the States, it was insisted that we continue to take delivery of automobiles months after the end of the war. The price of these stocks was fixed in dollars at a time when the dollar was only worth 8 francs, and we are now having to pay at the rate of 14 francs to the dollar.

"Despite all this the American automobile industry protests because a few thousands of her own vehicles are likely to be thrown on her market. America seems to look on the return of these vehicles as unfair competition, forgetting that in the first place she forced us to absorb immense stocks for which we had no need, thus flooding our market and contributing in a very large degree to the present glut. It is fortunate for us that there was no clause in the agreement against the return of this material to America, and personally I only hope that the whole of the remaining American automobile material will be shipped back to its country of origin."

PUSH STRAIGHT SIDE TIRES

NEW YORK, May 9—The executive committee of the foreign trade division of the Rubber Association of America has adopted a tentative program covering foreign advertising and publicity. The committee is giving its attention to the promotion of straight side tires abroad and protection against price declines on foreign sales. Reviving European competition has made necessary immediate action on the straight side tire problem.

Production in April Exceeds 1920 Total

Ford Output of 90,125 Leads Former Year by 40,000—Most Companies Gain

DETROIT, May 11—Automobile production in the Detroit district in April numbered 140,955 vehicles, compared with 119,213 in April, 1920, and 105,245 in March of this year. Ford production alone in April amounted to 90,125 cars and trucks, as compared with 51,066 for the same month last year.

Dodge also increased production last month and went several hundred over the record for April, 1920. Buick showed an increase of several hundred over March, although its April output was approximately 3000 behind that of April, 1920. Chevrolet, which was about 1000 behind April of last year, increased its output over March by about 2000.

Dort's April output was slightly in excess of March, but about 300 under April, 1920. Hudson and Essex both ran considerably behind the figures for a year ago. Hupp, on the other hand, with an output of approximately 2000 last month, showed an increase of about 700 cars over the same month last year and approximtely 600 more than in March.

The Lincoln Motor Co. built an average of 15 cars a day last month, and is operating on a schedule of 17 a day for May. The Olds Motor Works reached a production of about 2800 last month, which was about the same as in that month last year and an increase of 500 over March.

Packard built 625 "single sixes" last month, as against 670 in March, and 700 "twin sixes" in April, 1920. Paige slumped slightly in April in comparison with April, 1920, and also with March of this year.

Reo made a big spurt last month, producing 2750 cars and speed wagons, as compared with 2350 in March and a decrease of only about 300 as compared with April of last year. Studebaker, with an output in its Detroit and South Bend plants of 7825, went close to 3000 over March.

Body Shortage Slows Reo

April production schedules which were outlined in March failed to materialize in most instances. This was due to various causes. Reo, for example, was forced to curtail production because of inability to obtain bodies. Officials of the company said to-day that if an adequate supply of bodies could have been obtained production would have run close to capacity. An interesting fact in connection with the Reo business is that its foreign trade has fallen to approximately half its normal total. This company will make practically the same number of vehicles in May as in April, working short time but with a full force.

Oldsmobile shipments in the first quarter of this year were approximately 5000, as against 8500 for the same period last year. Olds is working full time with a force practically normal, building "fours" at Saginaw and some light "eights" at Lansing.

Olds production figures for the last five months, which are more or less characteristic of most companies, show the steady upward trend of business. In December, Olds built an average of 33 cars daily, in January 47, in February 40, in March 82 and in April 100. The rate for May thus far has been 104. The schedule for June is 119. These figures refer to the Saginaw plant. The company has had no truck production.

Lincoln Adds Distributers

The Lincoln company has increased the number of distributers from 15 to 50 in the last 60 days, and President Leland says the company is selling all the cars it can make, chiefly in New England and on the West coast.

The Denby Motor Truck Co. built 70 vehicles in April, which was about 35 per cent of capacity. General Motors turned out 650 at its Pontiac plant.

The business of parts manufacturers in the Detroit district showed an increase for April over March. Continental Motors is operating about 55 per cent of capacity, and the Timken-Detroit Axle Co. about 20 per cent.

The Motor Wheel Corp. reports a payroll larger than at any time since Jan. 1, having taken on 400 in the last 60 days. The Wilson Foundry & Machine Co. at Pontiac expects to be working at 50 per cent of capacity by the middle of May with a large increase in number of employees.

The O. J. Beaudette Co. of Pontiac now has 1085 men working in its body shop and is working night crews in its metal and tool departments. The Michigan Drop Forge Co. also has returned to a normal basis in the number of employees and is above normal in production. The factory is working 20 hours a day with two shifts.

SUPREME SUES ON STOCK

AKRON, OHIO, May 10—Suit to collect $200,000 alleged to be due on unpaid subscriptions for stock in the Supreme Cord Tire & Rubber Co. of Akron has been filed in the Summit County Common Pleas Court by Scott Kenfield, receiver of the company. B. L. Eaton of Greenville, Pa., is sued for $100,000 for stock which he is said to have subscribed for in April, 1920. Eaton was the company's former fiscal agent. The other defendants to Kenfield's action are all directors in the defunct company.

F. PHILIP DORN DIES

CLEVELAND, May 9—The death is announced of F. Philip Dorn, for twenty years secretary and general manager of the American Ball Bearing Co. His health began to fail several years ago and he retired from active business when his company was merged with the Standard Parts Co. A year ago he suffered serious injuries in an automobile accident and this hastened his d-ath.

Position of Willys Steadily Improves

Stockholders Told of Reduced Bank Loans—Sales Policy Conservative

TOLEDO, May 11—Reorganization of the internal affairs of the Willys-Overland Co. was made complete at the meeting of stockholders held here to-day when the executive committee was increased from five to seven members and the finance committee was eliminated. President John N. Willys addressed the stockholders and promised them that he would devote his entire time to the rehabilitation of the company until it gets back into the front rank.

"I shall work harder in the next twelve months than I ever did until I know that Willys-Overland is in its rightful position," Willys declared.

"This institution is my pet and I have just as much faith in it as I ever had. I shall not shirk my responsibility to the stockholders."

Willys told the stockholders that there will be no immediate reduction in the prices of the company's cars notwithstanding many rumors that Overland would join the companies making price cuts.

"We are watching the situation closely and are pursuing a conservative sales policy," Willys said.

"There is a market for the cars at the right value. The history of the automobile industry is not over yet. Companies that will survive conditions will be those that have the best management and which have eliminated loose methods. We have cut expenses to the bone. There are many bright spots in the future and we have reason to be hopeful.

"We have $6,700,000 in cash on hand. Agents throughout the nation report increasing inquiries for our cars. Last week showed the biggest increase in retail sales since last September. We are building the best organization we ever had at the Toledo plant and we will continue on a conservative sales policy.

Report to Show Profit

"We owe $20,000,000 less than we did a year ago. We have cut our inventories down to $38,000,000. Our annual report, which has been delayed for several days, will show a profit for the year."

The stockholders re-elected substantially all of the old directors; they are: J. N. Willys, W. P. Chrysler, C. B. Wilson, James E. Kepperley, J. R. Harbeck, E. R. Tinker, Elisha Walker, Edward F. Swift, Rathbun Fuller, C. B. Mertz, George R. Spencer and C. E. Killinger.

Willys praised the work of Charles B. Wilson, executive vice-president of the local plant, who, he declared, has succeeded in geting the plant down to an economical, efficient basis.

Maxwell Holding Company Formed

$40,000,000 West Virginia Corporation Also Will Take Over Chalmers

NEW YORK, May 11—The Maxwell Motor Corp., capitalized at $40,000,000, has been incorporated under the laws of West Virginia to take over the assets of the Maxwell Motor Co., Inc., and the Chalmers Motor Co. The company is authorized to manufacture and construct automobiles, motors, engines, etc., and to do all things incident to the business of building motor cars.

Formation of the new corporation is one of the final steps in the reorganization and consolidation of the Maxwell and the Chalmers interests. It had been supposed that the Chalmers name would be retained in the corporate title of the new company, but it apparently has been lost, although manufacture of the car will be continued. The physical assets of the Maxwell company in Detroit will be bid in to-morrow at a receiver's sale by the reorganization committee headed by Walter P. Chrysler. No other bids are expected. When the process of acquiring the assets of the two companies is completed they will be assigned to the West Virginia corporation.

The incorporators of the new company are clerks in the law offices of Albert Rathbone, the attorney who represents the reorganization committee. Directors and other officers will be elected as soon as the reorganization is complete and the board will include representatives of both the Maxwell and Chalmers companies.

The stock of the Maxwell Motor Corp. is divided into 200,000 shares which have a par value of $100 each, and 800,000 which have a total value of $20,000,000. The charter was the first large one issued in West Virginia since the enactment of the non par stock law. The company is the second largest ever granted a charter by the Secretary of the State of West Virginia.

Court Denies Appeal to Stop Maxwell Sale

DETROIT, May 11—United States District Judge Arthur J. Tuttle yesterday denied a petition of first preferred stockholders of the Maxwell Motor Co. in which the petitioners asked to intervene in the sale of the company, set for to-morrow.

The petitioners asked to intervene on the grounds that the proposed merger of the Maxwell and Chalmers Motor companies would take away their holdings and give them only a small share of the stock of the new company.

The court ruled that such a step would prevent reorganization of the company and thereby endanger the future of the concern.

Attorneys for the reorganization interests argued that the reorganization plan was fair, giving all classes of shareholders representation in the new company and making it possible to procure funds with which to liquidate the more than $15,000,000 indebtedness of the concern and to continue in business.

The petition of Holmes Jones of Wilmington, Del., asking a stay in the sale pending settlement of litigation in Delaware courts, was dismissed by Judge Tuttle on the grounds that it contained improper statements.

Attorneys for the first preferred stockholders obtained permission from Judge Tuttle to file a new petition for intervention at the time of the court's confirmation of next Thursday's sale.

According to certain holders of first preferred stock, under the reorganization plan stockholders surrender $17,603,964 of first preferred, according to book values, and get in exchange $2,561,013 of stock in the new company. Of second preferred, it was alleged, $2,172,337 will be exchanged for $987,441 in new stock. The common stock is reported as of no value, but the holders will get in return therefor $501,384 of new stock. Holders of Chalmers preferred will receive $1,029,600 in new stock for $4,519,722 old stock, and the holders of common stock, of no value, will get $557,543 of new stock.

Judge Tuttle held the concern must have new money in order to save that already invested. He said bankruptcy would ruin the company and declared to stop the sale would likely kill the whole undertaking. Appointment of a permanent receiver, he said, would be a detriment to shareholders in that it would interfere with sales, for no man would buy a car from a concern in receivership.

G. M. Export Names Officers

NEW YORK, May 12—At a deferred annual meeting of the stockholders of the General Motors Export Co., directors were elected as follows: Curtis C. Cooper, Paul Fitzpatrick, J. Amory Haskell, Norval A. Hawkins, Alfred P. Sloan, Jr., Peter S. Steenstrup and Alfred H. Swayne.

At the subsequent organization meeting of the directors, the following officers were elected: Haskell, president; Fitzpatrick, vice-president; Steenstrup, vice-president; Swayne, vice-president; Austin S. Murray, treasurer; Thomas S. Merrill, secretary, and George H. Bartholomew, assistant secretary.

Body Receiver Named

DETROIT, May 12—The Security Trust Co. has been named receiver for the Detroit Weatherproof Body Co., with a factory at Corunna, Mich., pending sale of the property. The action is a friendly suit, brought by the Michigan Steel & Metal Co. The body company has liabilities of approximately $650,000 and assets estimated at present market value to be worth $200,000. They consist chiefly of materials which actually cost about $700,000.

Stockholders Ratify Goodyear Financing

Almost Unanimous Sanction Given Program—Seiberling May Stay as President

AKRON, May 12—Stockholders of the Goodyear Tire & Rubber Co. ratified yesterday the $85,000,000 refinancing and reorganization program. More than 90 per cent of the common stock and more than 82 per cent of the preferred stock voted in favor of the execution of a first mortgage on the company's property to secure $30,000,000 in 20-year 8 per cent first mortgage gold bonds and $30,000,000 in 10-year first mortgage 8 per cent gold debentures.

Action of the stockholders completes the necessary steps preliminary to definite reorganization of the company. Plans of reorganization and the new official personnel will be announced at noon Saturday, to which time the meeting was adjourned. President F. A. Seiberling was given an ovation by stockholders and was unanimously elected chairman of the meeting. As he called the session to order the stockholders rose and cheered him.

No intimation has been given here by the interests which now control the company concerning the new management. It has been persistently reported, however, that G. M. Stadleman, one of the vice-presidents, would succeed Seiberling as president. On the other hand, the reception given Seiberling by the stockholders has led to belief in some quarters that he will be retained as president, although with greatly curtailed powers. The resignations are expected of C. W. Seiberling as vice-president and of P. W. Litchfield as vice-president and factory manager.

Timken Company Gets Truck Makers' Views

DETROIT, May 12—More than two score manufacturers of assembled trucks in which products of the Timken-Detroit Axle Co. are used, responded to an invitation from Fred Glover, general manager of the Timken company, to attend a meeting here yesterday for a discussion of the unit parts servicing problem. The conference was called by Glover to obtain the views of the truck makers on this subject. He informed them his company, while desirous of giving the best service possible to the public, was anxious to adopt whatever plan was most satisfactory to the manufacturers themselves.

Several of the manufacturers expressed their opinions on the subject, but no decision was reached. One proposal was that a dealer "pool" of all parts be established in the hope of insuring service, rather than direct distributing depots maintained by parts manufacturers.

Kansas City to Show Evil of Credit Ban

Automotive Organizations of Entire Federal District Back Liberality Appeal

KANSAS CITY, May 9—The visit of Governor Harding of the Federal Reserve Board to Kansas City May 21, arranged through the National Automobile Dealers' Association, will be the occasion for a conference with representatives of the automotive industry of the Tenth Federal Reserve District.

The most elaborate feature of the Harding visit will be a dinner Saturday evening, May 21, at the Hotel Muehlebach; but this will be chiefly the opportunity for the delivery of an address by Governor Harding to the industry. There are to be conferences during the day in which automotive distributors from many states will participate with Federal Reserve officials and Governor Harding.

Arrangements for the governor's coming are being made by E. E. Peake, secretary of the Kansas City Motor Car Dealers' Association. He will be met at the train Saturday morning by the directors of the association, who will take breakfast with him at the Hotel Muehlebach. The governor will then be taken for an outing in a ride over the boulevards.

For the business conference and the dinner, the Kansas City Association has tried to provide representation from every organized group of automotive distributors in the Tenth Federal Reserve District. The conference Saturday afternoon will be the opportunity for presenting to Governor Harding and J. Z. Miller, governor of the Kansas City Reserve Bank, the subject of rediscounts of automobile paper.

Many to Present Subject

To present this subject, besides the men from the Kansas City Association, will be one man from each of the automotive organizations of the district. These representatives will be selected from the committees of three from each organization, invited to Kansas City to meet Governor Harding at the evening event. Through this arrangement, the situation throughout all the states, and parts of states of the entire district will be laid before the federal bank officials, and the size of the industry in the West will be demonstrated, as well as the phases in which the previous attitude toward automobile paper has affected various interests.

At the dinner, besides the members of the local association, there will be present members of the Kansas City Tractor Club, bankers whose institutions constitute the Kansas City Clearing House Association, committees from each of the 30 civic bodies represented in the Club Presidents' Round Table, and the committees of three men each from the automotive organizations of Kansas, Nebraska, Colorado, Missouri, Arkansas, Oklahoma and Texas. In the last-named group will be committees from some sections that have not established organizations, the men invited being from the industry, however.

Acceptances have been received to most of the invitations transmitted to dealers in the territory. It is expected that attendance at the dinner will reach 600.

Governor Harding will spend at least one day, perhaps more, in Kansas and Oklahoma, prior to the Kansas City meetings. He will have opportunity to secure information from the districts visited, and will therefore reach Kansas City with a fresh knowledge of conditions. He is to address a bankers' meeting at Topeka Friday on the subject of motor car paper.

Governor Hyde of Missouri will be present at the dinner to deliver an address of welcome.

Hart-Parr Cuts $200 on Model "20" Tractor

CHARLES CITY, IOWA, May 9—The Hart-Parr Co. has reduced the price of its "twenty" tractor from $1,195 to $995, factory cash list. This places the "twenty" in actual competition with all makes of tractors in the 10-20 class. The factory is gradually increasing production of this model and shipments are moving forward steadily.

In addition to this price cut, the Hart-Parr Co. has improved and extended the scope of its sales financing plan, thereby helping the dealers still further to solve their financial problem.

A meeting of divisional sales representatives from all parts of the United States and Canada was held at the factory last week. It was the general opinion that the worst of the business depression is over and that bright sales spots are appearing where dealers doing systematic work actually are selling tractors. It is expected the next sixty days will see a rapid improvement in the tractor market.

The Hart-Parr factory has not been closed entirely but has been running on a limited production schedule because it was determined not to pile up an inventory but rather to manufacture only as fast as the field absorbs its product. The steel foundry was reopened last week.

FORT WAYNE CONDITIONS GOOD

FORT WAYNE, IND., May 9—Business among the local automotive concerns is very much on the up-grade. Dudlo Mfg. Co., makers of magnet wire used by Ford, has been re-employing men right along; General Electric Co. is picking up, and the manufacturers of lock devices for cars are also showing a distinct spurt in business. Among the retailers business is brisk. Several dealers state that business so far this year is as good or even better than it was up to the same time of last year. Business generally throughout this section has been pretty fair all spring.

METAL MARKETS

IT would seem as though the steel market, for the time being at least, is once more obstructed by anticipation of further price reductions. The general expectation is that the leading interest will not delay unduly long readjustment of its selling prices, once the 20 per cent cut in labor costs, which will go into effect shortly, has become operative. Moreover, buyers look for additional wage cuts by the "independents" and the latter may shave their prices even before the United States Steel Corporation does, provided actual orders can be booked as the result of such cuts. The blind alley which the market presents at this writing discloses in nearly every department remarkable pliancy of prices, a condition that is the natural forerunner of the lowering of quotations. Those who disseminated early in May news of heavy buying of sheets by one of the large builders of low-priced passenger cars have admitted freely that the actual tonnage placed was very light, and that what really did happen was that a number of sheet producers were asked to furnish their lowest quotations on a modest amount of deferred deliveries. This tonnage was pyramided by multiplying the quantity under discussion by the number of producers who were asked to quote. In fact, very little of the tonnage actually ordered by this interest represents new business, nearly all of it being on account of old contracts prices governing which have been amicably and equitably adjusted. A good deal of this sheet tonnage consists of material for frames that is sold on a plate basis. What orders were placed for the latter stock, which runs No. 12 gage and heavier, are presumed to have been taken at very close to 2c., Pittsburgh base. The bulk of this body stock, as well as of the light sheets which were ordered forward from northern Ohio mills, is for immediate requirements, and no fresh commitments for deliveries beyond the next four weeks are reported. Body builders, credited with having inquiries from the Cadillac Motor Co., are canvassing the market for quotations on suitable gages of sheets. Report has it that this company has placed a fair-sized order for cold-finished steel bars. Nowhere, however, is there any indication of buying for deliveries beyond June 30, and this stresses the belief of buyers that prices for third quarter deliveries will shortly move in their favor.

Pig Iron.—Cleveland pig iron interests report that the Ford Motor Co. is again placing orders with automotive foundries for castings conditional upon purchases of pig iron from the Ford furnace. The market for foundry and malleable remains slow with quotations generally on a basis of $24@$24.50, valley.

Steel.—Producers of cold-rolled strip steel are increasing their operations as the result of better inquiries from those who make automotive parts. Nominally the cold-rolled strip steel market is on a 5.50c. basis, while the hot-rolled is quoted at 2.75c. All of this buying, however, is for prompt shipment.

Tin.—The tin market presents the strange spectacle of having been lifted 20 per cent over its 1921 bottom without the least sign of a recovery in consuming demand, speculation having performed this feat unaided by consumers.

Lead.—It remains to be seen whether the advance that has elevated lead prices in the "outside" market to over 5c., New York, will be sustained. Basic conditions, however, are conceded to have improved.

FINANCIAL NOTES

Fisher Body Ohio Co. stockholders will receive one-fifth of a share of Fisher Body Corp. stock and $3 in cash under the exchange plan now declared operative. The Fisher Body Corp. guarantees the payment of the current quarterly dividend upon the preferred stock of the Ohio company down to and including the dividend payable on July 1, 1922. The company also agrees to pay on or before that date the accrued dividends for the year 1920. The dividend accruing April 1, 1921, is expected to be paid by the Ohio company.

H. H. Franklin Mfg. Co., in a balance sheet as of Dec. 31, shows total assets of $19,174,-902, in which is included property, $7,738,595; cash, $1,748,295, and inventory, $7,614,696. Liberty bonds total $684,630 and accounts and notes receivable $591,203. Liabilities show an increase in the preferred stock from $2,000,000 in 1919 to $3,324,800, and in common from $1,858,700 to $6,887,478. Accounts and notes payable total $7,233,180. Reserve for depreciation totals $1,049,014.

Parish & Bingham Corp. in a balance sheet as of Dec. 31 shows total assets of $5,696,770, an increase of $210,184 over Aug. 7, 1919. This includes cash of $281,419; inventories, $1,957,704, and accounts receivable of $375,844. The company's surplus of $2,332,363 is approximately $800,000 less than the surplus on the 1919 date. Real estate and buildings and machinery and equipment, however, has grown $1,200,000 since 1919.

Premier Motor Corp. in a balance sheet as of Dec. 31 shows assets and liabilities of $3,225,682. The assets include an inventory of $1,218,622; cash, $15,615; accounts receivable, $72,550; reserve on drafts, $207,-884; patents, good-will, etc., $443,719. The liabilities include deferred liabilities of $881,-227; accounts payable, $94,056; acceptances payable, $78,573; notes payable, $403,794, and dealers deposits of $20,166.

Pierce-Arrow Motor Car Co. for the first quarter of 1921 reports net operating loss after depreciation, charges and taxes of $489,502. In the first quarter of 1920 earnings amounted to $717,265, which, after payment of preferred dividends, amounted to $2.07 a share earned on common stock. The deficit this year is ascribed to poor truck business.

Michigan Drop Forge Co. shows total assets of $598,808.83 for 1920, with surplus of $86,136.32. Cash in hand and in bank was $39,925.07; accounts receivable, $53,175.10; notes receivable, $25,361.09. Inventories are given as $244,024.05; reserves, $87,085.09. Current liabilities were $72,989.11.

Timken-Detroit Axle Co. has declared the regular quarterly dividend of 1¾ per cent. on preferred stock June 1, to stock of record May 15. The company, however, has passed the dividend on common. The last bi-monthly dividend of 2 per cent on common was paid January 15.

Nash Motors Co. paid a dividend of $1.75 a share on the preferred stock on May 2. On the recommendation of President C. W. Nash the board of directors authorized some important extensions to the company's present plants.

Kelly-Springfield Tire Co. has issued $10,-000,000 in notes as part of its plans for financing, through a syndicate composed of H. P. Goldschmidt & Co., Lehman Bros., Halsey, Stuart & Co. and Goldman, Sachs & Co.

Willard Storage Battery Co. of Canada, Ltd., has been incorporated with a capital of $500,000 and head office in Toronto, Ont.

Titan Automatic Tool Co., Inc., Brooklyn, has filed schedules in bankruptcy with liabilities of $66,068 and assets of $61,139.

Willys to Float Bonds to Meet Bank Loans

TOLEDO, May 10 — Announcement was made here this week that the Willys-Overland Co. expects to take care of its bank loans, due Nov. 1 under the extension agreement, by means of a large bond issue to be offered to the public. If such a plan is carried into effect it probably will mean abandonment of the proposal made some time ago by the bankers interested for a consolidation in a new corporation of the Willys-Overland Co., the Willys Corp. and the other interests controlled by John N. Willys. Increased business recently has permitted substantial reductions in bank loans but they still run into many millions of dollars.

As a new means of increasing sales of Overland cars, each of the 7000 employees in the plant here has been made a salesman under a new plan by which he is paid $10 for each prospect reported which results in a sale before June 1.

Lockwood to Continue Accessory Production

KANSAS CITY, April 30—The purchasers at bankruptcy sale of the Lockwood Mfg. Co. have announced plans for operating the Lockwood automobile accessory factory as a unit in the business of the Baker-Lockwood Mfg. Co., Inc., Kansas City. The purchasers were W. C. Sommerville, president, and Walter L. Wilson, vice-president and treasurer, of the Baker-Lockwood Company. There is to be no change of name or official roster. The autmobile accessory factory will be operated as the Lockwood factory, with Wilson as general manager. Sommerville will manage the Baker factory. R. M. Secor, secretary of the Baker-Lockwood company, is made sales manager of the Lockwood factory business, Secor having had charge of the automobile accessory sales, with headquarters in New York until about a year ago, when the Lockwood interests withdrew from the Baker-Lockwood company, taking the autmobile accessory business with them.

INTERLOCKING TO PAY CLAIMS

AKRON, May 11—Officers of the Interlocking Cord Tire Co. have petitioned the court to absolve the receivership and dismiss Elihu Harpham as receiver. It is stated that an agreement has been reached with the creditors under which the company will pay 15 per cent on claims 30 days after the discharge of the receiver, 15 per cent in three months thereafter, 20 per cent six months thereafter, and the remainder within a year with promissory notes bearing 8 per cent interest. The statement is made that stockholders have raised sufficient money to cover the first payments to creditors.

BANK CREDITS

Written exclusively for AUTOMOTIVE INDUSTRIES *by the Guaranty Trust Co., second largest bank in America.*

NEW YORK, May 12—Secretary Mellon summed up present conditions by saying that the financial situation was improving and that the industrial situation was practically unchanged. The action of several of the Reserve Banks in the past week seemed to confirm his judgment of the financial situation. Following the reduction of its discount rate by the Boston Federal Reserve Bank several weeks ago, the New York Bank last week announced a reduction of its discount rate on commercial paper from 7 per cent to 6½ per cent. The 7 per cent rate had been in effect since June 1, 1920. Since that time the Atlanta Bank has reduced its rate from 7 per cent to 6 per cent, and the Chicago and Minneapolis Banks from 7 to 6½ per cent each. The Dallas Bank is now the only bank in the system which maintains a 7 per cent rate on commercial discounts.

The New York call money market eased last week after opening on Monday with a renewal rate of 7 per cent. The renewal rate for the remainder of the week was 6½ per cent. There was a freer supply and an easier undertone after the New York Bank had announced the cut in its discount rate. The range for the week was 6½ per cent to 7 per cent, as against 6 per cent to 7 per cent the week before. Time money also showed a slight easing. Sixty to ninety days' and four months' paper was quoted at 6¼ per cent to 6¾ per cent, and five and six months' paper at 6 per cent to 6½ per cent, as against 6½ to 7 per cent for all maturities up to six months in the previous week. The amount of business done was moderate, but trading was dull with a disposition to wait on further reductions in rates.

The stock market last week showed a decided upward trend, with a reaction, however, over the week-end. Many industrial stocks made new highs for the year, as did also a few railroads. The bond market was also buoyant, with many foreign government and municipal bonds and our own Victory 4¾s making new high records for the year. The same tendency was noticeable in the foreign exchange markets, where as many as ½ dozen European currencies made new high records for the year. The pound sterling at $3.98⅛ was at the highest since last June, and the French franc at 8.36½ was at its highest since last July. Exchange on Norway and several of the South American countries, on the other hand, made new lows for the year.

HOOD STARTS THREE SHIFTS

WATERTOWN, MASS., May 9—Evidence of marked improvement in the tire trade situation is shown by the increased activity of the Hood Rubber Co., manufacturers of Hood tires and tubes, which to-day began working three full shifts.

MEN OF THE INDUSTRY

Guy H. Peasley has been named sales manager of the Olds Motor Works, succeeding Charles A. Tucker, who resigned to devote his entire attention to the business of the Nebraska Oldsmobile Co., Omaha, of which company he is president and general manager. Peasley has been with Olds since 1911, when he started as a stenographer and bill clerk in the sales department. He worked his way up by successive steps, having been distribution manager for four and a half years, and during the past year assistant sales manager.

Homer K. York has been appointed assistant secretary and treasurer of the Indiana Truck Corp., Marion, Ind. Previously he had been supervisor of production and service for four years. Cecil B. Warner has been appointed western manager for the company, with headquarters at San Francisco. He was formerly connected with the Nelson and Gramm-Bernstein.

Homer J. Forsythe, manager of the construction division of the engineering department of the DuPont Co., has been transferred to the position of assistant general manager of the Hyatt Roller Bearing Co. of Newark, N. J., a subsidiary of the General Motors Corp. Forsythe had been with the engineering department of the DuPont company since August, 1906.

Ralph D. Webster has rejoined the selling forces of the Wire Wheel Corp. of America, and for the time being will make his headquarters in Detroit. Webster, a real veteran in the automotive industry, and a graduate of the older bicycle trade, was formerly sales manager of the controlling wire wheel organization.

John Jay Ide, who has been a frequent contributor to AUTOMOTIVE INDUSTRIES on aircraft subjects, has been appointed technical assistant in Europe of the National Advisory Committee for Aeronautics. His headquarters will be at the Paris office of the committee. He sailed May 3.

Edmond Rumpler, director general of Rumpler Auto & Airplane Works of Bavaria, accompanied by his purchasing director, Herman Aumer, is spending some time in Detroit visiting factories and conferring with business men with a view to the purchase of machinery for his plant.

Don Warren has been appointed vice-president and general sales manager of the Wolke Lead Batteries Co., Louisville. Elmer Brandell has been appointed advertising manager and W. G. Sauer has been appointed manager in charge of sales and sales promotion work.

P. J. Eubanks, who for the past two years has been serving as chief engineer and manager of the Aero Products Co. of Cleveland, has resigned to devote his entire time to the duties of chief engineer of the consulting engineering firm of Rush & Eubanks, that city.

E. J. Mueller, domestic sales manager of the Harley-Davidson Motor Co., is leaving that organization. He has no definite plans for the future, but intimates that he will continue in the motorcycle business, possibly in the retail sales field.

W. B. Blood, vice-president Campbell, Blood & Trump, has been made director of sales and advertising of the Ray Battery Co., Ypsilanti, Mich. Blood will retain his offices with the former concern in an advisory capacity.

C. L. Alexander has been appointed manager of sales promotion for the Elgin Motor Car Corp. He has been assistant sales manager since October, 1920, and formerly was connected with Lozier, Dodge and Maxwell-Chalmers.

H. G. Shirley, who has become well known to the automotive industry as a highway speaker, representing the Federal Highway Council, has been named as highway engineer for Baltimore County, Maryland.

O. N. McCool, who was formerly sales manager of the Commonwealth Motors Co. at Chicago, has joined forces with the Seneca Motor Car Co. at Fostoria, Ohio, as its Western representative.

O. M. Peters, formerly heavy line works manager of the Emerson-Brantingham Co., Rockford, Ill., has been appointed general works manager of the American Machinery Co., Kennett Square, Pa.

S. S. Jenkins has been appointed general sales manager of the Bijur Motor Appliance Co., Hoboken, N. J. He was formerly Detroit district sales manager for the company.

INDUSTRIAL NOTES

Toledo Automotive Products Co. has taken an exclusive license for the manufacture and sale of the Dorr Miller differential. Among the officials and stockholders are G. Huette and R. W. Randall, formerly of the Falls Motor Works; A. R. Class, president of the Toledo Steel Products Co.; C. E. Thompson and J. A. Krider, of the Cleveland Steel Products Co.; G. S. Salzman, of the H. J. Walker Co.; R. M. Bean, of the Durston Gear Corp.; D. A. Shaw, president of the Grant Motor Car Corp., and R. J. Goldie, of the Columbia Axle Co.

Milwaukee Circulating Pump Co., manufacturing circulating oil, water and other fluid pumps, and a subsidiary of the Milwaukee Shaper Co., has been acquired by a new corporation, the Cramer Mfg. Co. of Milwaukee, capitalized at $50,000. The present plant will be continued until such time as business warrants the erection of a new works. Officers of the Cramer company are: President, William L. F. Graf; vice-president and general manager, Robert Cramer; secretary and treasurer, William E. Graf.

Bridgeport Coach Lace Co. has established a factory branch at 1449 So. Michigan Avenue, Chicago, where a complete line of its products will be carried. T. N. Wakeman will be manager of the new branch. The company was formerly represented in Chicago territory by Blumenthal Bros.

Milwaukee Snow Conveyor Co., a new $25,000 corporation, has started production of a new type of rotary snow plow designed by A. F. Krueger, Milwaukee. It will be built for mounting with tractor and motor truck chassis, street and steam railway trucks, etc.

Mutual Truck Mfg. Co., Sullivan, Ind., has abandoned its intention of removing its plant to Peru, Ind. A. W. Petrie, inventor of mechanical features of the truck, has sold his interests for $50,000. It is thought he may start a factory at Peru independent of the Mutual company.

Gregory Tire & Rubber Co., Ltd., Vancouver, B. C., has started operations and will have a capacity of 500 tires and 1000 tubes a day when in full production. The company is incorporated for $1,500,000. Morton Gregory is president.

Cleveland Tractor Co. will operate temporarily on part time. The factory has been in full operation all winter. Business of the company is good and it is expected that dealers will liquidate their stocks in the near future.

Taft-Peirce Mfg. Co., manufacturer of machinery and tools and employer of 700, is shutting down May 9 for a week and will open again May 16 on full time. It has been operating on a four-day basis.

Independent Tire Co., Chicago, has changed its name to the Better Tire Co. No change has been made in the personnel or management, and the policy of the company will remain as heretofore.

Alvord Reamer & Tool Co. has opened a direct factory branch in Chicago under the management of C. B. Cole, formerly manager of the Union Twist Drill Co. at Chicago.

No-Leak-O Piston Ring Co., Baltimore, reports a sales increase for the first quarter of 1921 of 75 per cent over business in the 1920 quarter.

International Motor Co. has removed its New York offices to the new 22-story office building of the Cunard Line at 25 Broadway, which was opened this week.

To Merge Three Plants of Kelly-Springfield

NEW YORK, May 9—J. V. Mowe, general sales manager of the Kelly-Springfield Tire Co., who has returned from the formal opening of the company's new $11,000,000 plant at Cumberland, Md., announces that the twelve acres of manufacturing space now available in the new factory will make it possible to combine the Buffalo, Worcester and Akron factories in one plant, thereby producing cord and fabric casings, tubes and solid truck tires on a scale which the company never before has been able to approach. The immense new plant is said in some respects to be the finest in the world. Cumberland was selected because of its strategic location for the distribution of tires, the shipment of crude rubber from nearby ports, the proximity of the West Virginia coal fields and the favorable labor situation.

STEVENSON TO START PLANT

DETROIT, May 6—The Stevenson Gear Co., incorporated with a capital of $3,600,000, will begin work this month on a factory to cost $1,500,000 and to employ about 500 men. The company is headed by Richard T. Wingo, president and other officers are Frank C. Sibley, secretary, and G. W. J. Linton, treasurer. G. E. Stevenson, inventor of the product the company will manufacture, and E. B. Johns are members of the board of directors with the officers. The company will manufacture gears on special machines, the invention of Stevenson, and expects to be in production in the fall. The Stevenson Gear Co. of Indiana, the parent company, now has a $10,000,000 company in operation in that city.

Calendar

SHOWS

Sept. 28-Oct. 8 — New York, Electrical Exposition, 71st Regt. Armory, Electric Equipment, Machinery and Vehicles.

Nov. 27-Dec. 3—New York, Automobile Salon, Hotel Commodore.

January — Chicago, Automobile Salon, Hotel Drake.

FOREIGN SHOWS

May 28, 1921 — Czecho-Slovak International Automobile Exposition of Cars, Trucks, Tractors, Motorcycles and Equipment. Prague.

May 28-June 8 — International Automobile Exhibition, Basle, Switzerland.

June, 1921—Reykjavik, Iceland, Agricultural Exhibition—Agricultural Machinery—Icelander Agricultural Society, Reykjavik, Iceland.

September—Buenos Aires, Argentina, Passenger Cars and Equipment. La Pabellon de las Rosas. Automovil Club Argentino.

September—Buenos Aires, Argentina, Cars, Trucks, Tractors, Farm Lighting Plants and Power Farming Machinery. Palermo Park; Sociedad Rural Argentina.

September—Luxemburg, Luxemburg, Agricultural Sample Exhibition.

Oct. 5-16—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

Nov. 4-12 — London, British Motor Show, Society Motor Mfrs. and Traders.

May, 1922—Quito, Ecuador, Agricultural Exposition, celebrating Centenary of Ecuador. Automotive Section.

CONVENTIONS

May 17-19—Buffalo, Convention of Factory Service Managers, Auspices of Service Committee, N.A.C.C.

May 23-26 — Chicago, A.S.M.E. Spring Meeting, Congress Hotel.

May 24-28—West Baden, Ind., Summer Meeting Society of Automotive Engineers, West Baden Springs Hotel.

July 4-9 — Mackinac Island, Mich., Summer Meeting Automobile Equipment Association.

Oct. 12-14, 1921 — Chicago, Twenty-eighth Annual Convention National Implement & Vehicle A'ssn.

RACES

May 31 — Indianapolis, International Sweepstakes.

June 3-5 — Reno, Nev., First Annual Nevada Highway Road Race.

June 18—Uniontown, Pa., Speedway Events.

July 25—Grand Prix, Le Mans.

Labor Day—Uniontown, Pa., Autumn Classic.

S. A. E. MEETINGS

Dayton Section—May 17, H. L. Horning.

Cleveland Section—May 20.

Court Clears F. W. D. of Conspiracy Charge

MADISON, WIS., May 9—The Wisconsin Supreme Court has dismissed the complaint of R. P. Rohloff and other former stock holders in the F W D Auto Co., Clintonville, Wis., against directors and officers of the corporation, claiming conspiracy and fraud in keeping information of importance from them. The decision affects merely the right of a group to bring suit, and does not go into the merits of the action. It will mean that to recover it will be necessary for stockholders to sue individually.

The case involves hundreds of thousands of dollars to investors who sold their holdings just before large Government contracts were made. The plaintiffs were mostly original stockholders who helped form the F W D company in 1909. They claim the defendants induced them to dispose of their holdings in 1914 without informing them concerning actual and prospective contracts for thousands of F W D trucks for European belligerents. It is claimed that stock of a par value of $100, sold for that price in 1914, was actually worth $900 in 1917, 1918 and 1919.

Further action by the plaintiffs in accordance with the decision is promised immediately.

Factory to Direct Marmon in New York

NEW YORK, May 9—Under a new operating arrangement just worked out, the Marmon Automobile Co., of New York, distributor of the Marmon in the Metropolitan territory, will come under the direction of the officers of the Nordyke & Marmon Co. A. R. Heiskel, treasurer of the Nordyke & Marmon Co., has been elected president of the New York corporation, and S. S. Toback and Frank Carrie, vice-presidents. Toback, until he retired from the New York organization several months ago, to do some special work for the factory, was general sales manager. Carrie has been vice-president of the local company for some time.

The change in plan does not make the Marmon representation in New York a factory branch. The company remains a separate entity.

United Motors Tells New Service Plans

NEW YORK, May 10—Plans of United Motors Service, Inc., for the extension of replacement parts service direct to consumers through dealers and garagemen throughout the country were discussed at a three-day convention of New York territory distributors.

In introducing the plan Fred A. Oberheu, salesmanager, asked the distributors to assist in the extension of the service in their respective territories through selling small dealers and garagemen United Motors Service contracts. He pointed out that the prime object of the extension of the sales plan at this time was to make it possible for every motor car owner to get service and genuine replacement parts for any of the company's products through the establishment of selling and servicing connections in the smaller communities.

Oberheu also explained the national advertising campaign through trade publications, nationally circulated periodicals and newspapers, which is to support the extension plan with an educational program stressing the use of genuine parts, and enlarging on the fact that material and workmanship rather than dimensions are the factors to be considered in the satisfactory replacement of parts in these products.

The convention, which opened Monday, followed an interesting program of sales and service topics which were discussed by the following representatives of the company: F. A. Oberheu, salesmanager; D. M. Sweeney, superintendent of distribution; J. W. Parry, manager of the technical department, and R. L. Stevens, of the technical department.

Durant Coast Plant to Be Started at Once

OAKLAND, CAL., May 7—R. C. Durant, son of W. C. Durant, the former president of the General Motors Corp., has returned here and announced that the new Pacific Coast assembly plant of Durant Motors, Inc., will be located in this city and actual construction work is to be commenced within the next thirty days. The younger Durant is to head the Coast project just as he formerly headed the Pacific Coast Chevrolet organization.

The local plant is to be operated under the name of the Durant Motor Co. of California. The company is capitalized at $3,000,000, and of this amount young Durant has taken $2,000,000, while his associates and their friends have taken more than half of the remaining million. Among Durant's associates in the Coast unit of the Durant enterprise are C. M. Steves, A. and L. Warmington, H. T. McKnight, Capt. A. G. Waddell, J. E. Appleby, Capt. Eddie Rickenbacher, Chas. Dunham and a number of others.

Milwaukee Factories Show Early May Gains

MILWAUKEE, May 9—Gradual increase in the operating forces of the Milwaukee shops manufacturing motors, frames, parts and automotive equipment generally, which was the rule throughout April, has been slightly accentuated so far in May as the result of the broadening demands of passenger car and motor truck manufacturers. The makers of cars and trucks in this district likewise are effecting further increases in production, orders now being considerably ahead of current production. The situation is improving steadily, although slowly. Things are picking up in the tractor industry as well, but makers are still stocked with finished goods and a better demand has not yet been reflected into production requirements of an appreciable extent.

AUTOMOTIVE INDUSTRIES
THE AUTOMOBILE

VOL. XLIV. NEW YORK—THURSDAY, MAY 19, 1921 NO. 20

Rumors and June 30—Our Industrial Brakes

What follows is a consideration of some interesting questions of today. A few of them are: Who is buying? Why does he hesitate? Is price cutting the remedy? How to check rumors? What can we do?

By Clyde Jennings

RUMORS are the worst feature of the business situation to-day. As a matter of fact, rumors always are the chief source of trouble in a nervous market or an unsettled manufacturing situation. In this case it happens to be a market that is rapidly gaining strength.

Just at this time rumors are especially troublesome to the automotive industry. It is a rumor that keeps John Smith from buying the car that he has been looking at through the plate glass window for the last three months. He has heard many things. Just a few of the things that he has heard are:

> **The price of this car is to be cut week after next. (The fact that he has heard this once a week since last December makes him more confident as to the truth.)**
>
> **The company that makes this car is going to bust within a few days and the car will be an orphan.**
>
> **The dealer that handles this car is going bust and likely the new dealer will not take care of the older purchases.**
>
> **There is going to be a new car on the market soon, almost like this one that will be sold for about half of the money.**
>
> **The automobile factories profiteered heavily during the war and only a few of them have made proper adjustments in their prices.**
>
> **Dealers are making all kinds of wild allowances for used cars and if he scouts around and gets hold of a pile of junk he can sell to the dealer at a good price.**

These rumors are just a few of the things that the prospect is hearing among the "know it alls" whom he meets. The prospect has not recovered from that greatest of all rumor periods, the war, and he is inclined to listen to almost any fantastic tale.

Then there is another circle of rumors that is equally vicious. This is in the stock market centers. The tapes all day long carry notes that this company is "going to cut prices" or "reduce dividends," or both. Also it is told that the manufacturing companies are ignoring service, that service is being used "as a hold up to maintain profits" and so it goes. This particular form of rumor would not have been as important a few years ago as it is now. But in recent months the motor shares, through recently formed banking connections, have become an important factor in the great bourses. A sample of how these rumors break into print is well illustrated by the short article that follows. It was printed at the head of the financial news in a reputable New York newspaper. The headline was "BLUES IN WALL STREET OVER THE MOTORS."

While there was deep gratification over Germany's acceptance of the Allied terms it was not reflected yesterday in the stock market, where the greatest pessimism as to the immediate future of our own industrial situation prevailed. The traders talked of nothing else but dividend cuts and impending cuts.

Most of the rumors of this sort concern various motor companies and the corporations selling them supplies. Unfortunately, the spring boom in the automobile trade has been short lived. Buying has slowed up and the industry is apparently face to face with a readjustment as drastic as that to which other lines of business have been subjected and has in most instances met with liberal reductions in prices.

This necessity now faces the manufacturers and purveyors of cars as well as those who provide the accessories. Reports that another General Motors subsidiary and its principal rival will cut prices 20 per cent next week circulated yesterday, and there were stories of impending dividend cuts all around.

Heavy selling of Chandler was due to the belief that the company will not be able to maintain the quarterly dividend of $2.50.

American Bosch Magneto, which supplies many of the cars and motor trucks with magnetos, broke to 50½ on the statement that the company has been running into poor business because most of the companies at the beginning of 1921 had an oversupply of these electric distributors. The company has been paying dividends on a $5 annual basis and the next dividend is to be acted on early in June. The course of the trade in the meantime will determine the action to be taken then.

The effect of these rumors cannot be otherwise than bad, and such publicity as this financial item is especially bad, because a lot of men who deal in Wall street merchandise place great faith in what they hear there. Still more men who have never had an actual interest in anything that is sold in Wall Street, read these articles almost with reverence. The effect of the rumors is as widespread as the American motor trade.

The cure of these evil effects is not plainly seen, but the natural place to expect the answer is in automobile publicity. The reader turns there and finds exactly nothing that has any bearing on the subject that is uppermost in his mind.

Suppose the puzzled prospect turns to the advertisements for cars to find the maker's answer to the many rumors he has heard. It is an even chance that he will find that advertisement to be a wordy effusion on the use of the car for some entirely luxury purpose. He is urged to buy because the car will be a nice plaything for the children, or because he can take a long overland trip, which he cannot afford. Perhaps the price is on the advertisement and perhaps it is not. A year ago all advertisements had prices attached, and the manufacturers were quite proud of those prices. Indeed, a number of them pointed with pride to the price as an evidence of the excellence of the car.

Apparently every automobile and truck manufacturer in the country had a distinct steel-ribbed sales policy early in 1920 and he was proud of his strict adherence to it.

Sad is the contrast to-day.

Last midsummer AUTOMOTIVE INDUSTRIES printed some articles on merchandising—price cutting included—and these are especially good reading to-day. They were not prophetic, they were simply common sense. Some things were said about guarantees that were made when the first price cutting was announced. Some of the guarantees that were then made were withdrawn as soon as possible, others were not. To-day there is not a manufacturer in the industry who put out a hastily made guarantee that does not regrét that he did so.

Far be it from any one man to decide whether price cutting is the answer to the present ills of the trade. If the profit on the car is too high, then price cutting is one answer. But the real answer, as to what extent price cutting should be indulged in, must come from the cost sheet in the factory—not from an outsider. But some things can be set down with certainty. All of these things have been said before and will be said again. We venture a few:

There can be no dispute that the psychological attitude of the people is that prices should be cut from the war time standard.

The manufacturer who was well stocked with materials at after war prices is due for a loss.

He is going to take that loss whether he wants to or not. If he does not take it through cuts in sales price, he will take it through sales resistance and idle plant facilities.

A greater loss than inventory markdown is the disruption of an organization. This applies to the factory as well as to the sales field.

Now it is entirely possible that some vehicles to-day are priced at a perfectly reasonable figure, current priced inventories considered. The writer does not believe that the public is either illogical or unfair. It may seem so at times, but in the end it is not. A frank discussion of prices and reasons therefore in an advertisement would appear to be quite the right thing for a car or truck that is properly priced. This advertisement should not be mere "bunk." You cannot fool all of the people all of the time.

Those statements that were put out a year ago about it being impossible to lower prices because labor was not cheaper were "bunk" and they had just as much effect as "bunk" can be expected to have upon an intelligent public.

An automobile manufacturer recently showed to AUTOMOTIVE INDUSTRIES his report that labor in his factory constituted 14 per cent of the cost of his car. And this is quite a complete factory—not a mere assembly plant. The public knows, when it looks at a car, that relatively labor wage is not the chief thing to be considered in fixing the price of that car and it is absurd to expect such "bunk" to prevail. The public also knows that employers are saying freely that labor is more efficient than before—so labor is cheaper. Also the public has heard and believes much about reduced wages and if any particular factory has not reduced its labor prices this factory must say so.

Not long ago AUTOMOTIVE INDUSTRIES reported that a certain car had not been reduced in price. The salesmanager of that car objected and showed wherein the actual value of this car had been greatly increased and that the price had not been raised. This, he said, was equal to a reduction. But at that time he had not stated these facts to the public. His letter would have made a very excellent advertisement and would have convinced any intelligent prospect that this car had been reduced in price fully $200, but the prospect did not hear of this letter. He continued hearing rumors, however.

A group of sales managers recently raised an interesting question in a conference where AUTOMOTIVE INDUSTRIES was represented. It was about like this:

Who are our present customers, where are they getting the money and why are we not getting orders from our dealers for shipments after June 30?

These sales managers were much in earnest. They admitted that they were really surprised at the orders

received at the factories until June 30 and were entirely dissatisfied with what seemed to be in prospect after that date. The representative of AUTOMOTIVE INDUSTRIES answered the question in sections, in the main as follows:

Your present customers are in the main the "white collared class" that suffered so heavily during the war. They are the people sometimes called "middle class," who are the anchor of the great public. It was these people who had the hardest time getting through the war period. Pride caused them to make every effort to maintain a social position, intelligence caused them to continue the education of their children, and patriotism stirred them to heavy purchases of Liberty bonds and other securities. Comparatively their financial condition suffered. Their incomes were not increased in keeping with either the owners of business or with wage earners." Cost of living hit them sharply and their "solid" investments, usually public utilities or safe industrials, did not share in war profits. These people were the last to right their finances after change in living and investment conditions.

These people are now getting their money through an adjustment of the salaries that lagged behind wages and by interest on investments. These are the people who did not sell Liberty Bonds and now their gilt-edged securities that suffered during the war are doing comparatively better than they did during the high profit season.

These are the people who buy cautiously, carefully and with a full ability to pay their obligations. They are the people who used the old car a year or two longer or who put off buying a car. They are the people who are hardest to fool, because they do not act on impulse or hunch. It is to this class of buyers that a reasonable statement of quality or utility appeals. They do not want cars for purely pleasure; they cannot afford expensive luxuries. They would like very much for the manufacturer to justify their investment, for the purchase of a car is a considerable investment to this prospect. He feels that he must justify himself; not only in the investment as a whole but in the investment of a particular car. He will buy the lowest price car that he is convinced is in keeping with his social position and is economical in operation, other things considered.

The lack of orders after June 30 is because the dealers, either consciously or unconsciously are victims of widespread reports of price cuts on July 1. The factory man must remember that usually the dealer and salesman becomes a friend of his prospect. The prospect lets the salesman know that he puts a certain amount of faith in him and he asks certain questions—regular man to man fashion. This salesman, if he is worth having, does not pledge himself to things he does not know. He has heard that his factory is going to cut prices July 1. Where and when he heard this is not a part of this discussion. He has heard it and the factory has not said that it is not true. The factory has not announced any policy. When this man to man question is asked, the salesman is in a very embarrassing position. Does he owe his allegiance to the customer or to the factory? If he is as honest as a salesman ought to be, he tells the truth—says he does not know. He does not encourage the prospect. Consequently the dealer who gathers his reports from his salesmen, does not know what the prospects are for after June 30. So the dealer does not order.

Before the dealer can properly estimate his prospects after June 30, he must have a concrete idea of what his own and other factories are going to do.

In other words, the automotive industry must get a sales policy. At present it has none—and worse than that, it is not even answering the criticisms.

It is not strange that under present uncertain questions every shower finds a great many factories a long ways from home without umbrellas. A good many spring frocks have been damaged by these showers. When prices are cut on a well known line, and other manufacturers are asked about it, they bemoan the cruel fate that brought the shower at that particular time.

THE automobile and rubber industries have come back in a very definite fashion when some false prophets thought they had taken the full count for the time being. So far they have disappointed those who forecast a mere spurt instead of a continuous performance. There are still few belated thinkers who have overstayed their time and who fail to realize that automobiles are neither a fad nor a mere luxury but an essential and inherent phase of modern life.
—Archer Wall Douglas, chairman of the Committee on Statistics and Standards in Monthly Review of Business Conditions in The Nation's Business.

Far be it from the writer to say what the policy should be. That requires a careful study of the surroundings in the factory, into the bankbook of the manufacturer, into his reports on vehicles in dealers' hands and into the class of prospects that he hopes to attract. But there is a suggestion that can be passed on. It is this:

The sales reports all indicate many showers this season.

It behooves every person with automobiles to sell to dress accordingly.

If he prefers fine clothes and an umbrella, let him make that choice.

If he prefers a raincoat, that is up to him.

Perhaps he may prefer his golf tweeds.

The point is, let him decide how he is going out to await the showers. No matter what he wears, there is going to be damage, but the chief thing is that whatever dress he adopts, he must expect showers and not run for shelter when they come.

The method in this case is the same as has always won within the factory. Let your public—in this case the prospects—in on your plan and discuss the main problem and its details with them frankly and honestly. Let your dealers know what this policy is to be.

As we talk to dealers, we wonder if the manufacturer realizes just how important the dealer is in his contact with the public. The dealer is the spokesman for the factory, and often the dealer is spokesman for all factories to a particular prospect. It is well that this dealer should be informed as to factory plans. Don't be afraid to tell him.

The loss is in front of you—at least that part you have not written off—so decide how you are going to meet it —quickly or slowly—and then proceed on that plan determinedly and consistently. Perhaps you remember what Grant said about his Vicksburg campaign. Also you remember that he won.

Purposes of the Foreign Trade Finance Corporation Definitely Stated

There has seemed to be an element of uncertainty in the objects and methods of this new banking institution. In order to dispel this uncertainty, AUTOMOTIVE INDUSTRIES asked certain questions which the officials of the corporation have answered as set forth in the following article.

By George E. Quisenberry*

WHAT specifically does the Foreign Trade Finance Corporation offer to the automotive industry and what are the plans of its organization?

This question is one of exceeding interest, as the officials of this proposed foreign financing institution are endeavoring to close the company's books within the next ninety days and to commence active operations by Sept. 1. For the last four months the corporation has carried on a quiet campaign of education, endeavoring to show to the business interests of this country the imperative need for such an organization formed under the Edge law to solve the credit problems of American exporters. During this quiet campaign, according to officials, a considerable part of the proposed capitalization has been subscribed. Believing that conditions have been bettered to such an extent that the capitalization may be completed shortly, the corporation is now entering upon an intensive effort to complete its stock sales.

The automotive industries thus far have been one of the most liberal supporters of the plan. Several members of the organization committees represent the automotive industry and they have been among its active workers. Consequently, in order that the proposed institution might be better explained, officials of the corporation have been asked to go into more detail concerning its contemplated activities.

Specifically, the corporation plans to finance foreign sales of American products, both raw and manufactured. The extent to which this financing will favor the automotive industry depends upon the extent of support the corporation obtains from that industry in the sale of its stock. In other words, the industry will benefit in proportion to the interest it takes in the Edge organization.

Apportioning Credit

Will the corporation extend foreign credits to the automotive industry if manufacturers and exporters get behind it?

Yes. Under the Edge law, the Foreign Trade Finance Corporation will issue debentures to an amount of ten times its capital stock and can finance foreign trade up to the limit of its debentures plus the total of its capital stock. Another way to say this is that the corporation will be able to finance trade to a value equal to eleven times its capitalization. Theoretically, if the Sennett Motor Company subscribed $50,000, the corporation could finance its foreign trade to a total of $550,000, by the use of the original $50,000 capital and by the sale to the investing public of $500,000 debenture bonds.

*Managing Editor *El Automovil Americano*.

The corporation, however, cannot pledge itself at this time to any definite and concrete financing, such as pledging to the Sennett company an extension of credit totaling $550,000. The corporation reserves the right to pass upon each proposal for credit; it desires to use its assets in a manner best to promote American export trade in all commodities and it necessarily cannot forecast the channels into which this credit will be sent. The Sennett Motor Company as a stockholder of the corporation would naturally have a favorable standing over a non-stockholder and, undoubtedly, would profit thereby.

How It Will Work

How will the corporation finance foreign sales?

In effect, by opening letters of credit for foreign buyers in New York. When the Sennett company receives an order from, say, Argentina for cars valued at $75,000 upon which the buyer asks a credit of six or nine months, the Sennett company officials will refer the order to the corporation offices. The branch office of the corporation at Buenos Aires will be asked by cable if the risk is a good one. If so, the corporation will extend such a credit to the Argentine buyer. The Sennett company will ship the goods and obtain payment at New York by presenting the customary documents, the transaction in every way being similar to the present procedure of collecting against a confirmed letter of credit at New York or other ports.

The Sennett company has no connection with the credit in any way. That is entirely between the Foreign Financing Corporation and the buyer in Buenos Aires. The Sennett company forgets any liability for the deal as soon as it has received the money upon its shipping documents.

The only exception in the foregoing would be in a case in which the corporation might, for one reason or another, ask the Sennett company to indorse the paper of the Argentine company. In this case the manufacturer would be a party to the collection of the funds just as he is now in a transaction involving a secondary indorsement.

How to Join

In what way should the automotive industry join the corporation?

By subscribing to stock as individual firms, associations or districts. The corporation considers roughly the United States in districts similar to those of the Federal Reserve Bank. It prefers to consider its financing obligations in terms of these districts rather than by terms of industrial groups or other such divisions. It is active in this because of the fact that there might be need for financing from, say, the cotton and agricultural areas of

New Orleans and not the automobile manufacturing territory surrounding Detroit or Cleveland. Naturally, the corporation would not wish to tie up a large amount of funds awaiting the need of the Detroit district and failing to extend the required relief to the New Orleans people.

What does the corporation expect to achieve in its financing work?

It expects to take a prominent part in restoring prosperity to American industry. It will achieve its object when foreign buyers of American equipment buy freely in our markets; its profit will be derived from those transactions which are negotiated on long-term credit.

What are the provisions for the subscriptions?

Twenty-five per cent of the stock must be paid on the call of the directors that business will commence. The Edge law further provides that 10 per cent of the remainder shall be paid each sixty days, but objection has been made to this provision and the act is now being amended in Congress so that these additional payments may be made upon the directors' call. The amendment has passed the Senate and is now before the House with apparently no opposition to it.

Terms of Credit

What specific credits can the corporation provide?

Any credits which have a *longer* time to run than ninety days. In order that the company might not compete with domestic banks the Edge Act provides that ninety-day credits are the minimum. There is no maximum and the credits may continue as long as the bank decides. Branches will be opened in the chief foreign centers to pass upon credits, to supervise collections and to perform other necessary functions.

Has the promotion committee in mind a definite proportion between the capital of a manufacturer and the stock it should subscribe to the corporation?

No definite amount has been worked out, but may be determined on the amount of credit that might be needed.

Motor Cars Equipped for Casinghead Gas Tests

WHEN the casinghead gasoline industry was in its infancy, less than ten years ago, contracts were entered into by most of the mid-continent oil producers for the sale of their casinghead gas, which is the gas produced from oil wells. Gasoline plants were built wherever there appeared to be enough volume to justify their construction. Some of these plants returned large profits to their owners, others proved to be good investments, while a few operated at a considerable loss and were dismantled.

Experience quickly revealed that much of the casinghead gas did not contain enough gasoline to justify plant operation. Quantities of gas could not be conveniently carried to laboratories to be tested. It was not practical to pipe it for that purpose.

Thus necessity brought about the development of the test car, a miniature gasoline plant built on an automobile, to test the casinghead gas at the wells for its gasoline content—the number of gallons of gasoline that can be obtained from each thousand cubic feet of gas.

The use of the test car saves thousands of dollars each year for the buyers of casinghead gas, and insures the sellers an equitable method of determining value in disposing of their product.

The test car also has its use in the daily operation of gasoline plants. By it the critical pressure (the pressure at which the greatest yield is obtained) is found without disturbing the manufacturing process. It is also useful in maintaining the efficiency of the plants and in separating the gases of varying qualities to obtain the maximum yields.

The two principal methods in use to determine the yield in gallons per thousand cubic feet of gas are by compression and absorption tests. There is also the chemical test for the gasoline series in casinghead gas, but this test is seldom used in the field.

The compression test is most frequently employed and is usually designated in the gas selling contract, as the method to be followed in the so-called settlement tests, to arrive at the price to be paid the seller per thousand cubic feet for the gas until the next test is made. These tests are usually made quarterly or semi-annually.

The ordinary single-stage gas testing equipment consists of a small scrubber tank to free the incoming gas from water and whatever oil it may contain, a meter, a single-stage compressor, cooling coil and tank and a reservoir, called the accumulator tank, for collecting the gasoline as it comes from the coils while still under 200 to 300 pounds pressure. There are also the necessary gages for measuring pressure. All this is mounted on an automobile chassis. The power for operation is sometimes obtained from the automobile engine by jacking up a rear wheel and connecting it to the pulley of the compressor by a belt over a belt band on the rear axle.

In the compression method gasoline is manufactured from casinghead gas in the gasoline plants by compressing the gas in two stages, first by low-pressure and then by high-pressure compressors. With the purpose in view to more closely approximate plant production, it was found necessary in Oklahoma operations to develop a more efficient car than previously used. Instead of the ordinary single-stage, high-pressure apparatus, a two-stage, vacuum pump equipped test car was built. In this case the power is furnished from the engine through an auxiliary shaft direct from the transmission, which eliminates jacking up the rear wheel for power when in operation.

In the principle of operation this car is not very different from the single-stage machine in general use. However, it more nearly parallels the gasoline plant. Its vacuum pump permits of connecting into the lines, carrying the gas under the vacuum without the closing of any gates and a consequential loss of gas to the plant for several hours, and without loss of time to the gas tester waiting for pressure to build on the particular lease to be tested. The two-stage compressor, with both low- and high-pressure cylinders, necessitates the use of two sets of coils and accumulators.

The change in machine, however, does not modify the procedure of testing. This is governed by the rules and regulations made by the United States Interior Department. The minimum number of cubic feet of gas run in a test is ten. In order to eliminate errors in field calculations, 26.42 cu. ft. of gas are used, as this amount, passing through the meter at four ounces of pressure, yields one gallon of gasoline per thousand cubic feet of gas for every one hundred cubic centimeters of gasoline recovered. This is measured with the gasoline at atmospheric pressure after the temperature is raised to sixty degrees Fahrenheit at a rate not to exceed one degree every two minutes.

Many Important Subjects to Be Considered at S. A. E. Standards Meeting

Truck Division to report on recommended practice for important dimensions of front axles for trucks, and on truck body mounting dimensions. Specifications for electric cable among other important recommendations.

THE reports of the Society of Automotive Engineers Standards Committee Divisions covering their work for the first four months of 1921 has been forwarded to members of the Society and will be discussed at the Standards Committee meeting, which will be held at West Baden Springs, Indiana, on May 24. Parts of the report approved at the committee meeting will be submitted at the semi-annual meeting of the Society in session on succeeding days. Copies of the reports can be obtained without charge from the Society of Automotive Engineers, 29 West Thirty-ninth Street, New York City.

The reports consist of complete but concise statements of the practices and constructions recommended, together with such illustrations as are necessary.

The meeting of the Standards Committee, which will be held at the West Baden Springs Hotel, will be open to non-members of the Society who wish to attend. Those technically qualified who wish to discuss any of the reports will have the opportunity to do so. Written discussions submitted to the Standards Committee will also be given full consideration. The reports include recommendations on motor truck hubs, motor truck body installation dimensions, clutch release thrust type ball bearings, roller chains, roller chain sprockets, insulated cable, flexible disk couplings, headlamp brackets, lamp nomenclature, ball studs, exhaust pipes, square shaft fittings, universal joint hubs, radiator drain cocks, stationary engine belt speeds, stationary farm engine ratings, flywheel housings and other automotive parts and materials.

Clutch Release Type Thrust Ball Bearings

The Ball and Roller Bearings Division submits the following table of sizes for clutch release type thrust ball bearings as proposed recommended practice:

CLUTCH RELEASE TYPE THRUST BALL BEARINGS

Number	Bore	Width	Ball Diameter
1	1⅜	⅝	5/16
2	1½	11/16	5/16
3	1⅝	11/16	5/16
4	1¾	¾	5/16
5	1⅞	¾	5/16
6	2	¾	5/16
7	2⅛	¾	5/16
8	2¼	13/16	⅜
9	2⅜	13/16	⅜
10	2½	13/16	⅜
11	2¾	13/16	⅜
12	3¼	⅞	⅜

All dimensions in inches.
These bores and widths are intended for use with bearings with or without assembling bands.

Roller Chain Standardization

The Chain Division recommends the adoption of a standard tooth form, the pressure angle for a 6-tooth wheel running from 15 to 5 deg. and the pressure angle on a wheel of infinite diameter running from 15 to 30 deg., making the actual working face of the tooth a surface concave to the roller, the radius of which is approximately 1.3 times the diameter of the roller. The complete report covers the exact form of the tooth and the details of the cutters.

The Chain Division recommends also a numbering system for roller chains.

Insulated Cable

The report of the Electrical Equipment Division on Insulated Cable was formulated by a subdivision consisting of cable and passenger car manufacturers after a series of meetings at which the subject was exhaustively discussed. The recommendations of the Division will, if adopted by the Society, supersede the present S. A. E. Standard for Insulated Cable, adopted in 1916, which it is thought is not in accordance with the best engineering practice of to-day.

The proposed specifications cover conductors, cotton separators, rubber insulation, varnished cambric tape, braids, armor, tinning test, physical tests, miscellaneous tests and oil tests for braids as applied to high and low tension cables, and cables used for starting and lighting systems. The recommendations include tables giving armor thickness and width, number and nominal size of wires in stranded cable, thickness of insulation, carrying capacity, outside dimensions, etc. The report contains also a proposed revision of electrical equipment nomenclature.

Report of the Engine Division

The Engine Division recommends certain changes in the thickness of certain sizes of cast iron carbureter flanges used in stationary engines. The division also recommends that the following dimensions be added to the disk clutch flywheel standards:

Crankshaft flange counterbore: minimum diameter, 1¾ in.; minimum depth, 1/16 in.

Flywheel web thickness of counterbore, ⅝ in.

Clutch counterbore in flywheel: diameter limits, 11.500 and 11.503 in.; depth, 3/16 in.; corner radius, 1/32 in.

Report on Rating of Storage Batteries for Farm Lighting

The Isolated Electric Lighting Plant Division has, because of dissatisfaction with the standard rating for storage batteries adopted two years ago, prepared the revised rating standard printed below and recommends that it supersede the present standard:

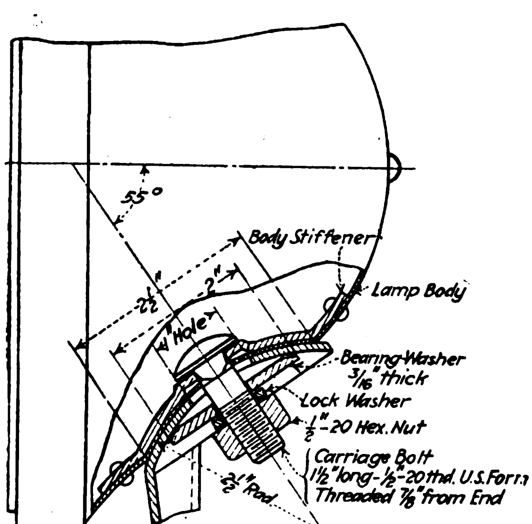
Storage batteries for farm light and power purposes shall be rated in terms of the number of hours discharge capacity at a constant rate corresponding to 300 watts, or fifteen 20-watt lamps.

In determining isolated electric light and power plant battery ratings, manufacturers shall consider:

1. The normal range of specific gravity which is recommended for the battery in service shall be used during the test.
2. The battery rating shall be established at an initial temperature of cells not to exceed 80 deg. Fahr.
3. The watts for rating lead batteries shall be based on a normal voltage of 2 volts per cell. The final voltage on continuous discharge shall not be less than 1.75 volts per cell.
4. The battery to be tested shall not be charged more than 120 per cent (in ampere-hours) of the last previous discharge.
5. The resulting test shall indicate the number of hours of service a lead-acid battery will give when discharged at a constant rate corresponding to 300 watts.
6. At 200 watts, 32 volts, the constant discharge rate shall be 6.25 amps.

Headlamp Brackets

The Headlamp Bracket Subdivision of the Lighting Division has, in cooperation with the lamp manufacturers, developed a universal fender type headlamp bracket which has been tested and found satisfactory in actual practice. This bracket has a spherical mounting surface for the lamp body, the radius of curvature of the surface being 2½ in. The lamp is held to the mounting surface by a single carriage bolt. The advantages of the proposed construction are twofold: the bracket permits universal adjustment of the lamp as well as interchangeability of lamps. The proposed bracket is shown in the cut herewith.



Proposed parabolic headlamp bracket.

Standard nomenclature for various types of lamps is also recommended in the report, while a revision of the present S. A. E. standard for lamp bases, sockets and connectors is proposed.

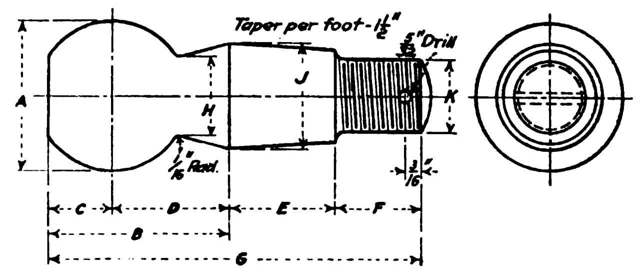
Miscellaneous Parts and Fittings

The Parts and Fittings Division recommends for adoption as S. A. E. recommended practice that

> The outside diameters of exhaust pipes extending from the engine to the muffler shall conform to the following inch sizes: 1, 1¼, 1½, 1¾, 2, 2¼, 2½, 2¾, 3, 3¼, 3½ and 4.

This recommendation was formulated in order to reduce the large number of exhaust pipe diameters used in present practice and make it unnecessary for the muffler and exhaust heater manufacturers to provide for an unnecessarily large number of sizes. Such a standard will be appreciated by the tubing mills and will facilitate deliveries and stocking. The recommendation is intended to apply to future production and is based on a survey of present practice which indicated that the 1⅝, 1¾, 2, 2¼, 2½, 2⅝ and 3-in. pipe sizes were most generally used.

The majority of steering gear connecting rods used are made with separate ball studs as this permits more satisfactory heat treatment. These studs are now made to many designs, differing but slightly in detail, but are much more expensive than standardized studs would be. The following table of proposed standard dimensions is therefore recommended:



No.	A	B	C	D	E	F	G	H	J	K
1	1	1⅜	7/16	15/16	13/16	13/16	3	⅝	0.766	⅝-18
2	1⅛	1½	½	1	13/16	13/16	3⅛	⅝	0.766	⅝-18
3	1¼	1 11/16	9/16	1⅛	1	13/16	3½	¾	0.875	⅝-18
4	1½	1⅞	⅝	1¼	1⅛	⅞	3⅞	11/16	1.000	¾-16
5	1¾	2⅛	¾	1⅜	1¼	1	4⅜	15/16	1.250	⅞-14

Proposed standard dimensions for ball studs.

It is recommended that the present S. A. E. standard for square shaft fittings be revised so that the shaft end and nut dimensions conform to the shaft end and nut dimensions of the present S. A. E. standard for taper fittings with plain and slotted nuts.

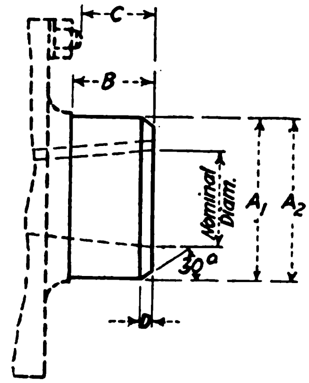
Universal Joint Hubs

In order to obtain better interchangeability between universal joints and transmissions, the Parts and Fittings Division recommends the adoption as S. A. E. Recommended Practice of the universal joint hub dimensions given in the accompanying table. The dimensions specified are of importance to the transmission manufacturers by eliminating many present variations in these parts, and to the transmission purchasers by making available transmissions having standardized shaft-ends.

The original recommendation of the Division, which was circularized among the universal-joint transmission, passenger car and motor truck manufacturers, specified dimensions for the outside diameters of the universal joint companion flange in order to permit the transmission designer to lay out the gearshift rods so that they would clear the companion flange. Criticisms received, however, indicate that the large number of different types and sizes of companion flanges would not permit specifying outside diameters without affecting individual design.

Stationary Engine Belt Speeds

The Stationary Engine Division recommends the adoption of the following belt speeds for stationary engines



<table>
<tr><th rowspan="3">Nominal Diam.</th><th colspan="4">Hub Diameter</th><th rowspan="3">Minimum Finished Length (B)</th><th rowspan="3">C[2]</th><th rowspan="3">D</th></tr>
<tr><th colspan="2">Lathe Finish (A_1)</th><th colspan="2">Ground Finish[1] (A_2)</th></tr>
<tr><th>Max.</th><th>Min.</th><th>Max.</th><th>Min.</th></tr>
<tr><td>3/4</td><td>1.280</td><td>1.270</td><td>1.253</td><td>1.250</td><td>5/8</td><td>9/16</td><td>1/32</td></tr>
<tr><td>7/8</td><td>1.530</td><td>1.520</td><td>1.503</td><td>1.500</td><td>3/4</td><td>5/8</td><td>3/64</td></tr>
<tr><td>1</td><td>1.780</td><td>1.770</td><td>1.753</td><td>1.750</td><td>3/4</td><td>3/4</td><td>1/16</td></tr>
<tr><td>1 1/8</td><td>2.030</td><td>2.020</td><td>2.003</td><td>2.000</td><td>7/8</td><td>3/4</td><td>1/16</td></tr>
<tr><td>1 1/4</td><td>2.155</td><td>2.145</td><td>2.128</td><td>2.125</td><td>7/8</td><td>3/4</td><td>1/16</td></tr>
<tr><td>1 3/8</td><td>2.280</td><td>2.270</td><td>2.253</td><td>2.250</td><td>1</td><td>3/4</td><td>3/32</td></tr>
<tr><td>1 1/2</td><td>2.530</td><td>2.520</td><td>2.503</td><td>2.500</td><td>1</td><td>3/4</td><td>3/32</td></tr>
<tr><td>1 3/4</td><td>3.030</td><td>3.020</td><td>3.003</td><td>3.000</td><td>1 1/4</td><td>15/16</td><td>1/8</td></tr>
<tr><td>2</td><td>3.280</td><td>3.270</td><td>3.253</td><td>3.250</td><td>1 1/2</td><td>1 1/16</td><td>1/8</td></tr>
</table>

All dimensions in inches.

[1]When specified the maximum eccentricity of the ground surface with respect to the hole shall be 0.002 in. (indicator reading 0.004 in.)

[2]The transmission design should provide clearance for the least distance from the end of the hub to the end of the flange bolt.

All fittings shall be S. A. E. Standard taper or spline fittings. The nominal diameter applies in either case.

Recommended universal-joint hub dimensions.

used for driving farm power equipment, such as ensilage cutters, milking machines and circular saws.

STATIONARY ENGINE BELT SPEEDS

Nominal Engine Rating, Hp.	Belt Speed, Ft. Per Min.	Nominal Engine Rating, Hp.	Belt Speed, Ft. Per Min.
1½	550	7	1340
1¾	600	8	1420
2	680	9	1500
2½	800	10	1575
3	900	12	1700
4	1030	14	1810
5	1150	15	1860
6	1250	16	1910

Stationary Engine Rating

The Stationary Engine Division recommends that the following horse-power formula be adopted as general information for publication in the S. A. E. Handbook as a means of securing uniform practice in rating stationary engines:

$$\text{Nominal Engine Horsepower} = \frac{0.7854\,D^2\,L\,R\,N}{13{,}000} \quad \text{where}$$

D equals the piston diameter in inches
L equals the stroke in inches
R equals the revolutions per minute of the crankshaft
N equals the number of cylinders.

The formula is based on a piston displacement of 13,000 cu. in. per min. per hp., as this is considered a very fair average factor for stationary and tractor engines burning either kerosene or gasoline. Various mechanical arrangements and refinements will, of course, influence the actual results on any one engine.

The results obtained using this formula are almost exactly 80 per cent of the brake horsepower under average good conditions and provide the desired 20 to 25 per cent of reserve power.

The Stationary Engine Division recommends as S. A. E. Recommended practice the adoption of the crankshaft and crankpin diameters given in the accompanying table.

CRANKSHAFT AND CRANKPIN DIAMETERS FOR STATIONARY ENGINES

Cylinder Bore	Crankshaft and Crankpin Diameter	Cylinder Bore	Crankshaft and Crankpin Diameter
3	1⅛	5½	2⅛
3¼	1¼	6	2¼
3½	1¼	6½	2⅜
3¾	1⅜	7	2½
4	1½	7½	2¾
4¼	1⅝	8	3
4½	1¾	8½	3¼
4¾	1⅞	9	3½
5	2	9½	3¾
...	...	10	4

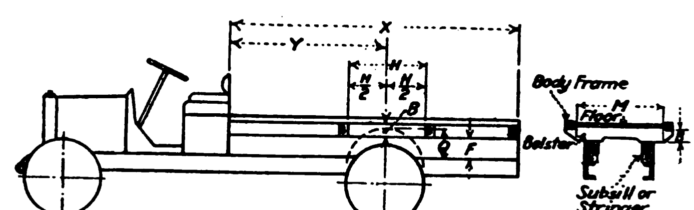
All dimensions in inches.

Other recommendations of the division include a set of dimensions for lubricator cups of various sizes and a table of water pot or hopper capacities for engines of various rated powers.

Motor Truck Bodies and Front Axle Hubs

The subject of motor truck body installation dimensions was first proposed to the Society about two years ago and assigned to the Truck Division. The original plan was to develop a standard which would include dimensions for the mounting of bodies on trucks and also frame widths, distance between spring centers, wheel treads and turning radii. A Subdivision was appointed which obtained considerable data on the practice at that time.

The original program has been reduced so that this proposal includes only dimensions for the stringers, bolsters, distance from the back of the seat to the center



F (Subsill) = (*Q* + Chain Clearance) — *B*

Nominal Capacity, Tons	Body Bolster (B)	Length Back of Seat to End of Frame (X)	Length Back of Seat to Center-Line of Rear Axle (Y)	H[1]	Dimension of Bolsters (M)
¾ to 1	5	108	60	32	36
1¼ to 1½	5	120	72	36	38
2 to 2½	5	132 156	81 98	36	38
3 to 4	5	144 192	90 114	36	42
5 to 6	5	144 192	90 114	36	42

[1] Dimension H permits a variation of plus or minus 2½ in. of the rear axle from the normal position.

Q is measured from the top of the chassis to the top of the tires when the springs are deflected to the "metal to metal" position.

Recommended dimensions for truck body installation.

of the rear axle, and the distance from the back of the seat to the rear end of the frame. The dimensions were quite generally approved as being suitable for the interchangeable mounting of truck bodies with the exception of special types such as large van bodies and special short dump bodies.

The proposal as now submitted by the Truck Division for adoption as S. A. E. recommended practice is shown in the accompanying drawing and table, and indicates the available space in which bodies may be mounted. The proposal also includes the nomenclature of the body mounting timbers, which at the present time are known by a variety of terms. It is believed that the proposal includes all the necessary dimensions for the installation of truck bodies by body manufacturers on trucks conforming closely to the dimensions given in the table, and that it will answer the requirements for such standardization which had been urged through the technical press for some time.

Readers of AUTOMOTIVE INDUSTRIES will recall that the report of the Truck Division on proposed hub standards submitted at the annual meeting of the Society last January, was referred back to the committee and later considered at a meeting held in Detroit on March 3. Other meetings of interested manufacturers were held later and the whole matter finally considered by the Truck Division meeting held recently in New York at which representatives of truck, axle, bearing and wheel makers were present. The whole proposal as presented to the Truck Division included two series of spindle sizes with their related parts in considerable detail. After thorough discussion of this proposal, it was deemed best to limit the proposed standard to only such dimensions as are essential for the interchangeability of bearings and wheels on the proposed series of spindles.

The Truck Division therefore recommends for adoption as S. A. E. recommended practice, the dimensions shown in the accompanying drawing and tables for installation of inch size roller bearings and metric ball and roller bearings.

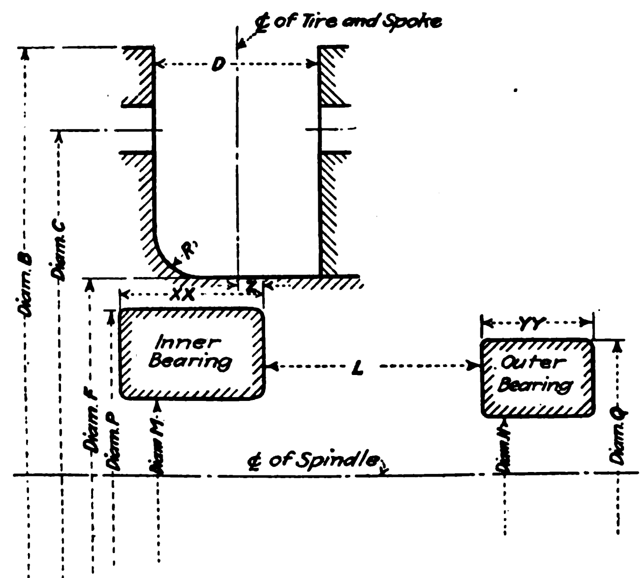


Diagram showing truck front axle hub dimensions referred to in accompanying tables.

TABLE I—DIMENSIONS FOR INCH SIZE TAPER ROLLER BEARING HUBS

Hub and Spindle Number	Letter	R5	R6	R7	R8	R9
Diameter of flange	B	9	9¾	10½	10¾	11¾

[1] When the outer hub bearing is a ball bearing, the space required for it is $(L + YY) - a$.

With approval of this report by the Standards Committee, it is proposed to continue this work to include a series of similar hub dimensions for passenger car front axle hubs and also if feasible, for a complete line of rear axle hubs for passenger cars and motor trucks.

Chairmen for S. A. E. Summer Meeting Sessions

THE following men are expected to serve as chairmen at the various sessions of the Summer Meeting of the Society of Automotive Engineers, to be held at West Baden, Ind., May 24 to 28: Standards Committee Meeting, afternoon, May 24, B. B. Bachman; Business Session, evening, May 24, President David Beecroft; Aeronautic Session, morning, May 25, Howard E. Coffin; Transportation Session, morning, May 25, H. W. Alden; General Research Session, morning, May 26, H. M. Crane; Combustion Session, morning, May 27, Thomas Midgley, Jr.; Fuel Research Session, morning, May 28, O. C. Berry.

Judges' Report on the 1920 British Tractor Trials

Much delayed notation of decision of event held at Lincoln six months ago is disappointing in that it does not state definitely individual results.

MORE than six months after the event, the judges' report concerning the tractor trials held near Lincoln, England, last September has been issued by the Royal Agricultural Society. It is a disappointing form of report for those makers whose machines did well, for beyond descriptive references and tabulated specifications it does not refer individually to the competing machines—except to mention again the "awards" that were made in the various classes a week or so after the trials.

The actual performances of the competing tractors are set out in one of the tables, but these are merely grouped in the various classes, with minimum, maximum and the average of the five best given under the different headings. The portion of this table dealing with internal combustion engined tractors and self-contained plows is given herewith; from this it will be gathered that, taking the average of each class in cost of fuel and labor per acre, the four-furrow outfits did not show up well compared with those with two and three furrow plows, while there is not much to choose between the two last mentioned and the self-contained three-furrow units.

Explanatory of this table it may be said that where two lines of figures are bracketed in respect of fuel, the second line represents what is termed the cost or consumption per "equivalent" acre, the latter basis being arrived at by reducing the drawbar pull to a standard of 500 lb. per furrow. Actually the drawbar pull varied from 335 lb. to 565 lb. per share in the light land; in the heavy land the maximum was 1250 lb. per furrow. An acre of the latter in the second set of figures would therefore be calculated as 2½ "equivalent" acres.

In the working out of costs kerosene is taken at the price paid at Lincoln, viz., 46 cents per Imperial gallon and gasoline at 82 cents (at normal rate of exchange). Labor is taken at 36 cents per hour.

The judges in their summary refer with approval to the fact that out of thirty-eight competing machines, two only retired during the trials. They also say that the uniformity of excellence greatly increased the difficulties of judging and that it would have required extreme uniformity (which was lacking) in the general conditions to have warranted arranging the machines in order of merit under the various headings—work done, amount and cost of fuel consumed, drawbar pull, mechanical design, etc. And yet they say that they had no difficulty in selecting the prize winner in each class.

As an appendix to their report, the judges publish two estimates of plowing costs, one from a man who farms in the district in which the trials were held and who gives the cost of horse plowing, and another from a farmer who gives both tractor and horse plowing costs from his own experience. The former's figures enable a comparison to be made between the average of the competing tractors.

The Lincoln farmer referred to gives the average cost of plowing 6 in. deep in the trials district with horses in 1920 as follows:

Light land ....$5.60 per acre
Heavy land ....$10 to $11 per acre

The other farmer's estimated costs are:

Tractor Plowing Per Acre

Wear and tear of tractor	$2.50
Kerosene, 4 gal. at 46 cents	1.84
Lubricating oil	0.36
Labor—one man at $17.50 per week; weekly average, 15 acres; cost per acre	1.12
Plow, shares, etc	0.60
Cost per acre	$6.42

Horse Plowing Per Day

Three horses at $2 per day	$6.00
One man and one boy, per day	3.60
Plow, shares, etc., per day	0.48
Estimated daily work, five-sixths of an acre	10.08
Cost per acre	$12.10

Class	Land	No. of Furrows (All 6x10 in.)	No. of Attendants	Time in Hours Per Acre: Minimum	Time: Average of Five Lowest	Time: Maximum	Fuel in Imp. Gallons Per Acre: Minimum	Fuel: Average of Five Lowest	Fuel: Maximum	Wages, in Cents, Per Acre: Minimum	Wages: Average of Five Lowest	Wages: Maximum	Fuel Cost, in Cents, Per Acre: Minimum	Fuel Cost: Average of Five Lowest	Fuel Cost: Maximum	Total Cost, Labor and Fuel, in Cents, Per Acre: Minimum	Total Cost: Aver. of Whole Class

NOTE.—The figures for minimum time and minimum fuel consumption per acre do not necessarily apply to the same tractor. The same is the case for the maxima.

Features of Mechanical Interrupters for Ignition Systems

Part I

An article pointing out the nature of the functions performed by an interrupter, in relation to other parts of the ignition system, and discussing the fundamental requirements of a well designed interrupter.

By Harry F. Geist

IT is very evident from the amount of attention that has been given to the development and design of the mechanical interrupter that it is a very important element of an ignition system.

It is the purpose of this article to point out the necessary functions that the interrupter has to perform in the operation of the ignition system and to discuss the fundamental considerations that must be borne in mind in the development of a good interrupter and of its connection with the rest of the ignition system.

In the design of such a mechanism as an interrupter, success must be based upon a sound principle and is attained by the proper proportioning of parts, by the proper selection and quality of materials and perhaps most important of all, by the workmanship represented in the quantity production of the mechanism. Because of the fact that the successful operation of the interrupter depends upon so many considerations, criticism of any of the designs shown would be out of place and is not intended. The service that any particular interrupter is giving will speak for itself better than any other form of analysis possibly could.

Evolution of High Tension Ignition Systems

The first electrical high tension ignition systems consisted of a vibrating induction coil that was energized intermittently by a battery of cells. In these induction coils the interrupter consisted of a magnetically operated trembler, constructed integral with the coil and operated by the magnetic action of the coil core, so that the timing of the system depended upon an extra mechanism known as a "timer" that was geared in timed relation to the engine. With such a system every time the timer would complete the circuit between the battery and the primary coil, a shower of sparks would be delivered to the spark plug at a frequency dependent upon the adjustment of the trembler and covering the complete period of closed circuit at the timer.

For multi-cylinder installations, the system required as many induction coils and timer contacts as there were cylinders, so that the timer served also as a distributer in the primary circuit of the system.

The first simplification of this system came in the form of a master vibrator which consisted of one trembler interrupter that was operated electro-magnetically by means separate from the coils and produced the sparks in turn in the particular coil with which the timer connected it.

At this same time the alternating current low tension magneto was coming into use. It was connected to a suitable step-up coil for energy transformation and was equipped with a mechanical interrupter in the primary circuit and a distributer for the high tension circuit. Both the interrupter and the distributer were constructed integral with the magneto, and were thus timed to the engine. The interrupter in such a system not only served its functions as a circuit breaker but took the place also of the timer. It is this same type of mechanical interrupter that to-day serves to break the primary circuit for spark production and to time the spark to the engine as well.

From this type of magneto and step-up coil system it was natural for the self-contained high tension magneto to follow, thus eliminating the separate step-up coil, but maintaining the same form of mechanical interrupter and high tension distributer.

The success obtained by the use of the mechanical interrupter and its single spark delivery, in the case of magneto systems, made its adoption the logical step in what is now the modern interrupter-distributor battery and coil type of ignition system. So that in the modern high tension ignition system, the mechanical interrupter serves both as circuit interrupter and as timer in both the magneto and the battery and coil systems.

The matter of its serving as a timer to the system is due to the fact that the interrupter is always geared in timed relation to the engine, and since its actuation is always affected by the rotation of the armature in the case of magnetos it is always in timed relation to the electrical firing range of the magneto.

In the case of so-called "variable ignition" the interrupter may be adjusted to actuate at any time desired on the firing range, while for "fixed ignition" the interrupter is always operated at the same piston position.

The principal functions performed by the mechanical interrupter are those affecting the electrical operation of the ignition system when the interrupter "makes" and "breaks" the primary circuit, but before attempting to study these functions, let us first consider a typical interrupter and its mechanical and electrical connections to a high tension magneto.

Interrupter Connections With Magneto

Fig. 1 shows a typical magneto interrupter and its connection with the rest of the machine. The breaker plate carries an insulated plate in which the insulated contact carrying screw is adjustably fitted.

Pivoted upon the breaker plate is also a lever arm

having two projecting ends. At one end of this arm the grounded contact is carried, and a spring, secured at one of its ends to the lever arm and at the other end to the breaker plate, tends normally to hold the two contacts together. These contacts are usually of a platinum-iridium alloy. At the other projecting lever end, a fibre bumper block is inserted for co-action with the cams, so that the rotation of the breaker plate produces an opening of the contacts every time the bumper block engages a cam.

The lever arm pivot fits into a fibre bushed bearing so that oil will not be necessary for lubrication. It is very important that the lever arm works easily on its pivot, without being loose, and it is especially important that it shall never stick. A retaining spring (not shown in Fig. 1 but shown in Fig. 9) is adapted to hold the lever arm in place upon the breaker plate. The lever arm spring is also backed up by buffer springs at each of its ends to relieve the strains that would otherwise cause fatigue.

The breaker plate is further equipped with a tapered concentric boss and key that fits into a female taper in the end of the armature shaft, and the entire mechanism is securely held in place by an insulated connecting screw that completes an electrical connection between the insulated breaker plate and the condenser plate, so that the connecting screw serves the double purpose of mechanically securing the interrupter to the armature

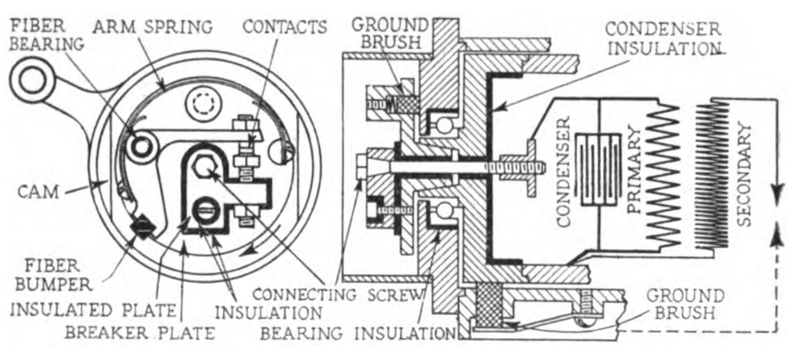

Fig. 1—Typical mechanical interrupter and its connections with magneto

and of electrically connecting the interrupter with the condenser.

A further electrical connection between the insulated primary winding terminal and the condenser plate ties the primary winding to the insulated breaker plate also.

The other side of the condenser and the other terminal of the primary winding are grounded to the armature core and thus are electrically connected to the breaker plate through the taper fit between the breaker plate and the armature shaft. From this arrangement it is very evident that when the interrupter contacts are together both the primary winding and the condenser are short circuited through the lever arm spring, the lever arm, the contacts and the connecting screw.

This short circuit allows the primary winding to generate and store energy with the rotation of the armature and keeps the condenser "empty" during the period of short circuit.

The cams which make possible the interruption of the circuit at the contact points, are mounted in a housing that is carried concentrically upon a flange projection of the armature bearing plate, and the housing is so adapted that it may be rocked on this dowel flange by means of a lever. With this adjustable breaker housing carrying the cams, it is evident that the time of circuit interruption can be changed to different armature positions and due to the fact that the armature is geared in timed relation to the engine, the resulting spark can be adjusted to occur at different piston positions.

For the "H" armature type magneto, represented in the figure there are two cams; one for the positive spark and the other for the negative spark, and they are so located that for the "advanced" engine firing position the circuit will be interrupted just following the magnetic break between the trailing armature core tip and the field pole shoe tip it is leaving, while for the "retarded" engine firing position the interruption can be adjusted to occur as much as 30 deg. of armature motion later. A stop pin usually limits the motion of the interrupter housing to the firing range of the magneto.

The interrupter housing is held in its place upon the armature bearing plate flange by a post and spring means clamping against a cover over the end of the interrupter housing.

As further features of interest, not essential to the interrupter, but to the high tension system as a whole, a grounding brush and spring makes a direct electrical connection between the magneto frame and the rotating armature so as to prevent the high tension spark current from passing through the bearings every time a spark is delivered by the secondary circuit. In addition to this precaution, the annular bearings sometimes have their races insulated from the bearing plates by the use of fiber.

A second grounding brush is mounted in the interrupter plate to engage with the armature bearing plate of the frame. This brush serves as an auxiliary to the above-mentioned grounding brush and serves especially for installations in which a switch is employed to short circuit the interrupter for cutting off the ignition.

Interruption of Primary Circuit

The most important electrical function performed by the interrupter is to break the primary short circuit at a time when the energy generated and stored in the primary winding is such that a high tension spark will be produced in the secondary circuit. In order to make this break of the electrical circuit as effective as possible, the separation that takes place between the contacts must be produced in a quick and decided manner, so that after the contacts have once separated, all the subsequent electrical action in the primary circuit will take place between the primary winding and the condenser.

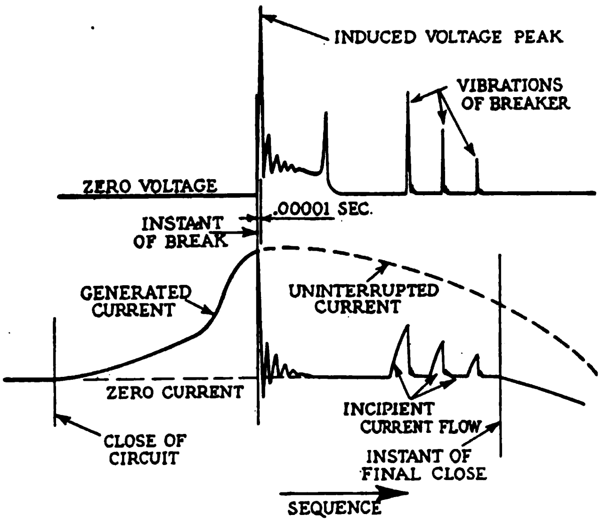
To accomplish this feat, the pivoted arm type of interrupter shown in Fig. 1 has been developed to a high degree of perfection, it being maintained that the rigidity of the arm assures that the contacts will positively and quickly separate when the fiber bumper engages with the cams.

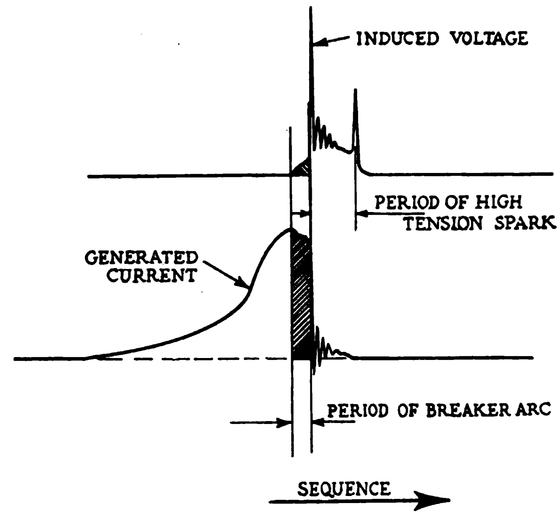
Fig. 2 is presented to show graphically the electrical phenomena of the energized primary circuit coincident to an interruption.

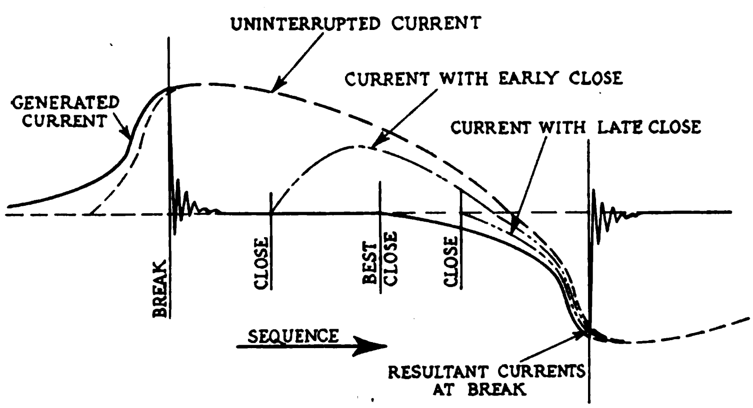
The lower curve, starting at the left, shows how the current is generated during a period of short circuit until it reaches about its maximum value at the instant of break. The upper curve shows that the voltage across the contacts during this period is zero.

If the interruption did not take place the current would flow as per the dotted line designated "uninterrupted current" and the voltage would, of course, remain zero.

But at the instant of break, two simultaneous results follow, first the current generation ceases and must drop toward zero, and second, the empty condenser which is







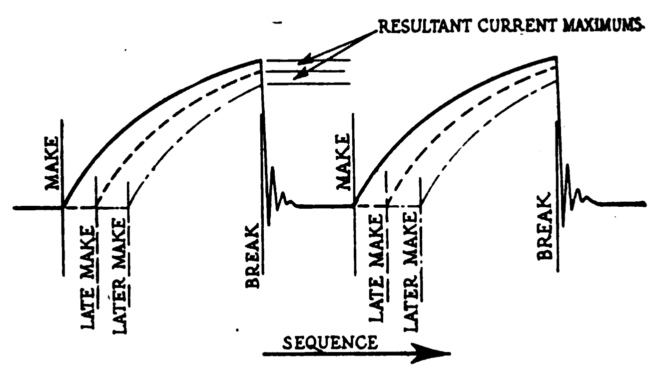


Fig. 2 (Upper)—Electrical phenomena accompanying break of primary circuit, including effect of vibrations
Fig. 4 (Lower)—Illustrating effect of time of make upon current values. (Magneto system)

Fig. 3 (Upper)—Phenomena typical of arcing at contacts
Fig. 5 (Lower)—Effect of interrupter closing on primary current. (Battery system)

suddenly thrown into the circuit across the primary winding will start to absorb a charge of energy from the primary winding.

The combination of these two results is that the current generation in the primary suddenly ceases and the primary energy tending to enter the condenser causes the primary winding current to drop toward zero precipitously, inducing a very high voltage per turn in both the primary and secondary windings. This induced voltage is shown in Fig. 2.

It is this voltage that initiates the spark at the secondary circuit spark plug and permits the secondary winding to discharge most of the energy in the form of a high tension spark.

The balance of the energy will oscillate electrically between the primary winding and the condenser until it is dissipated in primary circuit losses.

The effect desired in a quick break of the circuit is that the current shall drop toward zero and the voltage induced rise toward its maximum value as quickly and as directly as possible, so as to keep the period of time designated in Fig. 2 by ".00001 second" as small as possible.

While this period of time under perfect conditions is controlled by the balance of the electrical circuits and not by the interrupter, certain faulty conditions such as arcing at the contacts or a hesitating interruption of the circuit can affect this period of time very materially. These conditions will be discussed subsequently.

At the instant that the contacts first separate, the condenser will start to take on a charge of energy at a very high rate and the current flow into the condenser will therefore be very high, perhaps ten times or more the maximum winding current generated. The result is that this current will tend to take all the paths possible in getting to the condenser. These paths include the interrupter lever and its spring, which are intended to be its only path from the interrupter lever grounded contact to the breaker plate, and it is partly to prevent the rush of condenser charging current on the grounded side from flowing through the lever arm pivot and the cams, that the fiber bushing and the fiber bumper block are mounted in the interrupter. Fiber is also used at these places because of the excellent mechanical results obtained by a bearing between fiber and steel.

In some of the earliest types of magnetos, the practice was started of having a copper strip along with the interrupter arm spring to aid in taking care of this condenser charging current on the grounded side, but while this idea seemed to have considerable theoretical value, it was found by experience to be unnecessary.

Arcing at Interrupter Contacts

Following the interruption of the primary circuit, one of the most undesirable things that can happen is to have arcing at the interrupter contacts.

This arcing burns away the platinum contacts very rapidly when it is excessive, or it will also produce a coating such as an oxide on the contacts that will soon impair very much the operation of the system.

Some makers of magnetos advertise that a little arcing at the contacts is necessary to keep the contacts clean, but the writer believes the value of arcing in that direction rather questionable.

One of the principal functions of the condenser in a high tension ignition system is to prevent arcing by

handling all the energy that is not transferred to the secondary circuit, but even at best occasional arcing will occur. Continual arcing at the interrupter contacts is usually an indication of poorly balanced circuits or of a poor connection in the primary circuit.

Beside the evil effect of arcing upon the platinum contacts, this arcing when excessive also reduces the amount of energy that will be delivered to the high tension spark. This point is illustrated by Fig. 3.

Fig. 3 shows how the total period of sparking is divided between a period of breaker arc and a period of high tension spark, and shows that the high tension spark cannot begin to take place until after the primary circuit arc has ceased. Therefore if a large part of the energy available for a spark is spent in the breaker arc it must be very evident that the energy left for the high tension spark will be reduced that much. If you have ever watched a high tension magneto, on test, that would arc rather badly at times, you have perhaps noticed that the accompanying high tension spark was very poor. It is to explain this phenomena that Fig. 3 is presented. In Fig. 3 the shaded areas on the current and the induced voltage curves are components of the energy spent in the arc.

In addition to the evil effect of arcing upon the platinum contacts and the corresponding reduction of the high tension spark, arcing has still another detrimental effect upon the operation of the system. It seems that the amount of voltage that will be induced in the windings following the interruption of the primary circuit depends largely upon the amount of current flow in the primary winding just before break, that is the further the current has to drop toward zero following break the greater the induced voltage will be. During arcing, as shown by Fig. 3, there is a gradual fall of current so that when the condenser does get started, the resulting induced voltage peak will not be as great as it would had no arcing taken place.

When, as in some installations, the ignition system has all it can do under the best of conditions, it is very evident that arcing at the interrupter might cause the ignition to fail. The effect of arcing upon the voltage induced has a pronounced influence upon the slow speed performance of a magneto and in general it will be found that a magneto that arcs badly will not function at as slow a speed as it otherwise would.

Closing of Interrupter Contacts

While the breaking of the primary circuit is the important function performed by an interrupter, the circuit must close again to be ready for the next successive break, so that this closing or "making" of the short circuit is also important and has an important bearing upon the performance of the ignition system, whether magneto or battery system, especially at the higher speeds of operation.

To explain the importance of the phenomena of making the circuit, Fig. 4 is presented to illustrate what takes place in the case of magnetos.

In this figure the "uninterrupted" current and the "interrupted" current waves are superimposed in about their true relationship to each other.

The time of break of an interrupter is determined definitely by the position of the cams, but in most interrupters the time of "make" depends upon the relation of the reactionary forces of the lever arm to the arm spring force.

As the armature rotates and the interrupter lever arm is actuated by engagement with the cams, the arm receives a certain amount of throw and due to the inertia that the arm is bound to have the spring is unable to bring the contacts to a close immediately on passing the cam. This throw increases as the speed of the armature rotation increases and the result is that the "make" of the circuit may occur 45, to 90 or more degrees of armature rotation following "break."

During the period of "open circuit" following the interruption of the primary circuit and the high tension spark delivery, there is bound to be some residual magnetic flux cutting across the windings, with the armature rotation, that will generate an electromotive force in the windings.

If the "make" occurs very early after break, when this e.m.f. is of some moment, current will again flow in the primary winding. If the spark just delivered was of positive polarity current then this current will also be of positive polarity and due to the inductance of the winding it will tend to linger in the circuit beyond the armature position of no flux change; namely, the horizontal armature position, just as the "uninterrupted" current is shown to do in Fig. 4. The result is that when the armature passes the horizontal position and starts to generate current of negative polarity, a certain amount of energy will be required to neutralize the lingering positive current before the useful negative energy can be stored in the primary winding ready for the next spark. Or if the make occurs very late, that is very far beyond the horizontal armature position, the current generated for the next successive spark will be late in getting started. In the event of either a very early or a very late make therefore, the result is that the current for the next successive spark will not reach as high a maximum value as it would if the make occurred at about the horizontal armature position. It is to illustrate this point particularly, in connection with early and late making of the circuit and the general effect upon the resulting current maximum that Fig. 4 is presented. The resultant current maximum of course has a direct bearing upon the amount of energy that will be delivered to the high tension spark.

It is practically impossible to control the position at which the interrupter contacts will "make" in the usual type of interrupter for the different speeds that the magneto is subject to, but it so happens that at the slower speeds the amount of "extra" energy that will be generated drops off along with the tendency of the contacts to close earlier, so that if the interrupter is designed for satisfactory closing of the circuit at the higher speeds desired it will tend to regulate itself automatically very well for the slower speeds.

In the case of battery and coil systems, the time of make is also an important consideration. The phenomena are illustrated in Fig. 5, where it is shown that for any particular frequency of interruptions, as measured by the period of time between breaks, the time required for the contacts to close following break has a material influence upon the maximum value that the current will attain during the period of closed circuit for any particular coil.

It must be borne in mind that the rate of energization of a coil depends upon the electrical circuit characteristics and is always practically of a constant nature, while in a magneto the rate of energization tends to increase with increased armature speeds within certain limits.

In the case of the battery system, it must be evident that as the frequency of interruptions increases with engine speed, the period between breaks grows shorter and at the same time the tendency is for the make to occur later and later after break as the interrupter speed increases, with the result that the period of closed circuit gradually shortens at both ends and the high ten-

sion spark energy must decrease with increased engine speed. For these reasons the battery and coil ignition system delivers its best spark at slow speeds and gradually falls off as the engine speeds up.

Vibration or Bouncing of Interrupter Arm

Another important consideration in connection with mechanical interrupters is that of vibration or bouncing of the lever arm in closing.

The usual interrupter closes its contacts under the influence of a spring and since the arm has inertia during its motion there will be a tendency for the contacts to rebound or vibrate before coming to a final close. This bouncing will produce a series of incipient current flow impulses each time the contacts come together, and a series of induced voltage peaks each time they bounce apart. Additional strain upon the secondary insulation results from these induced voltage peaks and the vibrations delay the time of final closing of the circuit.

The electrical phenomena, including both the current flow impulses and the induced voltage peaks, coincident to vibration of the interrupter lever arm are shown in the curves of Fig. 2.

The results of the official tests conducted by the National Advisory Committee for Aeronautics to determine the "Heat Energy of Various Ignition Systems" as set forth in Report No. 56 show that in all magneto ignition systems the spark heat increases with magneto speed up to a certain speed. Beyond this speed, the energy begins to drop off gradually with further speed increase and in some cases a second rise in the curves takes place for still higher speed. While no explanation of the depression in the spark out-put speed curve was given, the writer ventures the belief that this depression in the curves was caused by the vibration of the interrupter arm and its effect upon the closing of the contacts.

These vibrations will have a certain period in any particular case dependent upon the relation of the numerous forces at play on the arm during the action of the interrupter, and it is not unlikely that the speed at which the maximum depression occurred in the case cited was such that it brought the arm in tune for maximum vibration. Increase in speed beyond this point would reduce the vibration again and permit the magneto to build up an increased amount of energy with it.

While the forces at play upon an interrupter arm are numerous and the reduction of vibration in any particular interrupter is purely a matter of experiment, it is highly essential to the reduction of vibration that the interrupter arm have a good bearing fit upon its pivot as a loose fitting arm will be free to vibrate badly.

Welding of Contacts by Condenser

It was pointed out in connection with the closing of the interrupter contacts that, during the period of open circuit following the break of the circuit and the high tension spark delivery, a residue flux cuts across the winding and generating an e.m.f. therein.

Since the primary winding is connected on open circuit directly across the condenser, it is evident that this e.m.f. will tend to charge the condenser.

From this it follows that if the contacts close either very early or very late while the condenser is so charged, this charge will be suddenly dissipated at the contact points at the instant they close. Short circuiting a charged condenser is always accompanied by intense heat at the points of contact and tends to have a welding effect upon them. The phenomena is accompanied by a shower of very small sparks that fly in every direction when the contacts come together. When these sparks are seen it is a sign that the interrupter is closing either too early or too late. So that beside the advantageous effect upon the maximum current produced by having the contacts close at a time of zero e.m.f. in the windings, this is also the time when no welding action at the contacts can occur.

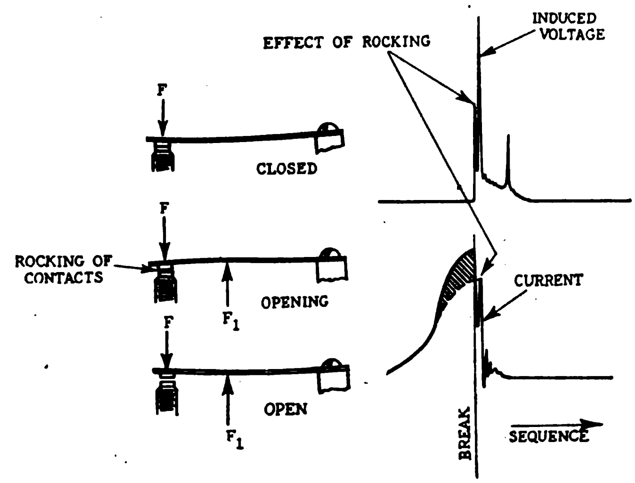

Fig. 6—Mechanical and electrical phenomena of simple spring type interrupter

In battery ignition systems there is no period of zero voltage during open circuit, hence the contacts are always subject to the necessity of discharging the condenser at every make. On the other hand the condenser capacity required for battery systems is much less than that required by magnetos so that the welding effect is not a grave concern.

Contact Material

It has been shown that the interrupter contacts are liable to be subject to such electrical phenomena as arcing, welding and the conducting of generated current, that they are subject to mechanical impact and the heating and oxidization that naturally results. In order to stand up in service under these conditions, the contacts have to be made of the very best material obtainable. A platinum-iridium alloy, containing from 15 to 20 per cent iridium, has been found to be the best material for ignition system contacts. This alloy oxidizes very slowly under average conditions and thus remains a very good conductor for the generated current. It is also hard enough to withstand the mechanical impacts it is subject to and to resist the arcing and welding actions in a very satisfactory manner. Because of the expense attached to these contacts attempts have been made to use tungsten, but while it has given satisfaction in special cases its general use has not been adopted. Tungsten seems to oxidize more rapidly than does the platinum-iridium.

In connection with interrupter contacts it might be well to mention at this time that it is highly important that oil or other foreign matter be kept from getting onto the contacts as it prevents the two contacts from making a good metallic "make" of the circuit.

It is because of this danger that interrupters are equipped with oilless bearings and no oil is ever admitted to interrupters except by means of a wick for oiling the cams for the interrupter fiber bumper arm. This oil should be used very sparingly.

Rocking of Contacts

From the very beginning of the use of mechanical interrupters for high tension ignition systems, efforts have been made to simplify it mechanically by eliminating the breaker arm. This is accomplished by mounting

the grounded platinum contact point directly upon the spring.

Fig. 6 is representative of the earliest types employing this construction, but in this particular embodiment of the idea which has now become almost obsolete, certain troubles arose that the writer has attempted to point out by means of the illustration, and it is, perhaps, due to these troubles that this particular form of interrupter has become practically obsolete.

The spring was connected directly to the breaker plate by a screw about as shown and due to a slight bend downward exerted a force throughout its entire length that can be represented as having a useful value F holding the two contacts together.

When the cam, or any medium through which it acts begins to exert a force F_1 tending to lift the spring and consequently its contact away from the insulated contact, the very first result obtained by F_1 is a tendency to relieve the spring tension from the point of its application to the point of application of F, hence that part of the spring tended to straighten out. The result was that instead of the contact being lifted quickly away from the insulated contact, it rocked from a flat surface contact to an outer edge contact before it finally lifted to a complete break.

This "rocking" or hesitating break is equivalent to a "break-make-break" action that seriously interferes with the efficiency of the energy transformation and transfer in the windings which should start at the very instant of first break.

The effect of this rocking is shown graphically by the current and induced voltage curves shown in the figure. The current at break tends first to take a very sudden drop toward zero for the induction of the high voltage necessary to initiate the spark, but being, as it is, followed almost immediately by a closing of the circuit again, the induced voltage is checked momentarily before the necessary spark voltage value is reached, causing it to drop toward zero again until the final break occurs. The current, of course, can never recover during the extra "rocking" made and so the induced voltage that does finally initiate the spark cannot be produced as effectively as it would have been had the first break been final and decisive.

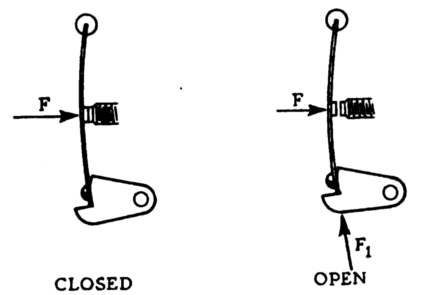

Fig. 7. Illustration of action giving parallel contact motion

The loss in effective primary current value is shown by the shaded area. Such a rocking break is bound to cause not only arcing at the contacts, but a welding action as well, hence the life of the contacts is bound to be short.

Certain modifications have been incorporated into this general type, shown in Fig. 6, that have overcome its troubles very well.

Parallel Contact Action

Fig. 7 is presented to show an interesting type of interrupter action that produces a very effective break. In this interrupter the contact is mounted on the center of the spring, one end of which is connected to the breaker plate with a slight freedom, while the other end connects to an actuating arm. A slight bow of the spring tends to hold the contacts engaged and they may be opened by a cam exerting a force F_1, as shown, that tends to further bow the spring against the force F.

A principal point of interest in connection with this action is that the force F_1 has to act through only about one-half the distance of contact separation resulting and a very quick separation of the contacts is obtained. Further it will be seen that the contacts open in an almost parallel relation to each other.

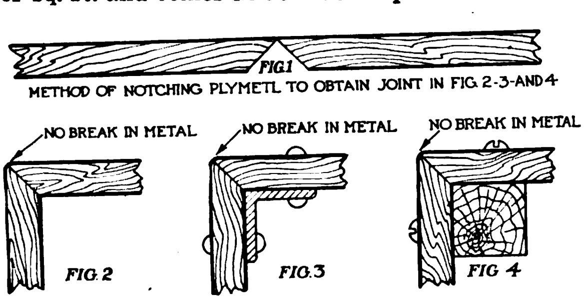
Parallel action of the contacts is a very desirable characteristic. It is not accompanied by a wearing of the contacts on one side as is liable to be the case in the lever arm type of breakers, so that when an adjustment of the contacts is made to take up wear, there is not the need for as much filing and dressing down of the contacts as is usually required. This is, of course, a very important item in the life of the contacts.

(To be continued)

Dashes and Body Panels of Metal Covered Veneer

A NEW material for automobile dashes and body panels is now being manufactured by cementing thin sheet metal faces to a relatively thick core of light-weight material. The sheet metal forms a smooth, impervious and durable surface. The core spaces the faces relatively far apart, making the material strong and stiff while still retaining lightness.

It is furnished from stock in panels 5/16 in. thick, with faces of black or galvanized sheet metal, No. 30 gage, and with planed wood veneer cores. It weighs about 1.8 lb. per sq. ft. and comes in 30 x 96 in. panels. It is claimed for the material that it is five times as stiff as a 5/16-in. solid wood panel and eight times as stiff as sheet steel of No. 19 gage, which has the same weight. The elastic limit in bending is 75 in.-lb. per inch of width or about five times the elastic limit of No. 19 gage steel. Impact, shearing strength and fatigue tests have also been made by the manufacturers with satisfactory results. The core subjected to tests was made of fir wood veneer, planed. The illustration herewith shows three methods of making a right-angled joint with this material which is known as Plymetl and is manufactured by the Haskelite Mfg. Co.



Three methods of making right angle joints with Plymetl, a veneer covered with light sheet metal

FOR students a motorist desiring to gain information concerning all branches of automobile construction and operation, probably no better method of handling the subject could be desired than that of questions and answers. This is the method used by Victor W. Page in his "Questions and Answers Relating to Modern Automobile Design, Construction and Repair," of which a revised and enlarged edition has recently been issued.

The nature and character of Mr. Page's work is familiar to automotive engineers, so that a detail discussion of the new edition need not be given here.

Development and Present Status of German Airships

The tables shown in this article include all the German airships built up to the present time, while the article describes the technical successes and failures of the various types. The performance of the R-34 is compared with that of the German L-59 which made a trip to East Africa.

THE Tables of German Airships on the following pages include all German airships built to date with the exception of a few built prior to 1910, which would be classified under the heading of miscellaneous types. These have been omitted because of their relative unimportance, since they could neither be classed as successful nor did they exert any important influence on the development of German airships.

The development of the non-rigid German airship can best be traced through the Parseval types. Their development covered the period of years from 1906, when the experimental PV Type was placed in service, to 1917 when the PL-27 was constructed.

The Parseval series were all built to the patents of Major von Parseval by the Luft-Fahrzeng-Gesellschaft (L.F.G.) at Berlin. That they were successful is attested by the fact that the company secured orders from Austria, England, Italy, Japan and Russia. The PL 22, 23 and 24 were laid down but never completed, probably because the rigid type was better adapted to purposes of war and the utility of the small non-rigid airship was eliminated with the advent of the large rigid types.

Starting with the PL-14, all Parseval airships had envelopes with the Parseval patent trajectory band system of car suspensions which was a very efficient system of non-rigid construction. The PL-25 had a small girder extending fore and aft from the center of the ship about 60 ft., and with the PL-27 really comprised a semi-rigid airship, although the Germans classify it as non-rigid. Under the envelope of this ship there is a fore and aft keel with a walkway which extends nearly the complete length of the ship. Beneath this, but forward, is the navigator's car and immediately behind it is the first power car. About half way along the keel are two side power eggs similar to those used in the latter types of Zeppelin airships, and at almost the extreme aft end of the keel is located another power car. The keel walkway carried the gasoline tanks and the water ballast bags as in semi-rigid or rigid airships.

The semi-rigid airships were of two types, that with the keel incorporated in the envelope as in the last Parseval airship (PL-27), and that with the keel slung several yards below the envelope, as in the Gross-Basenach or "M" type.

The most important semi-rigid airships constructed were the "M" or military types built for the Prussian Army by the Prussian Army Airship Works and were mainly the design of two men, Major Gross of the Prussian Army, and Herr Basenach. They were evidently not much of a success, for the later type of Parseval airship was given preference over the military types. In the early types of semi-rigid airships, those with the suspended keel, the gas tanks were carried in the cars, but in the later types with the keel incorporated in the bottom of the envelope, the gas tanks were placed in the rigid keel framework. This made it permissible to use lighter construction in the cars and utilize with slight modifications the existing keel framework, thereby effecting a saving in the structural weight of the airship.

The first rigid airship was constructed by David Schwartz in 1893 in Petrograd. It was composed of aluminum and was not sufficiently gas tight to be tested. However, in 1895 to 1897 he built in Berlin a new airship (47.5 m.) 155 ft. long (13.5 m.) 44.2 ft. in diameter, which had a total capacity of (3700 cu. m.) 130,500 cu. ft. The framework consisted of twelve rings and sixteen longitudinal aluminum girders and sheet aluminum was used for covering material. It was equipped with a Daimler engine developing 12 hp. at 480 r.p.m. The ship was inflated by using an interior bag, which, as soon as it was filled and the air had been totally displaced from the interior of the hull was torn up and pushed out through an aperture. This left the gas in direct contact with the aluminum envelope. The airship had three propellers, two on side brackets and the third between the gondola and the hull, and since it had no rudder, it was steered by this propeller arrangement. In its second flight on Nov. 3, 1897, the belting driving the propellers slipped off the pulleys and the helpless airship was dashed to the ground by a strong wind and wrecked.

The rigid airships were developed by two constructors, the Zeppelin Works and the Schütte-Lanz Company. Both types were composed of a rigid framework with a variable number of gas cells. In the Zeppelin type the rigid framework consists of longitudinal members running from stem to stern, and transverse members which run from longitudinal to longitudinal, around the ship, thus forming a ring. The material used for the construction is duralumin. In the first Schütte-Lanz airship the rigid framework was composed of diagonal members which ran spirally around the ship from stem to stern, and transverse rings as in the Zeppelin types. Too many difficulties in fabrication were encountered, however, and in the remainder of the Schütte-Lanz airships the girders run longitudinally and transversely as in the Zeppelin airships. The material used, however, in the Schütte-Lanz types was wood and all structural members were made of built-up wooden sections. When these ships were used by the navy it was found that the wood absorbed moisture and the airship became very heavy. In addition to this the glued joints opened up, but later through a new method of fabrication and chemical impregnation of the wood these difficulties were overcome. It is understood that at the time of the armistice

the Schütte-Lanz Company was preparing to use duralumin instead of wood for the construction of their airships.

It should also be noted from the tables that, while using various types of engines in the early days, each series finally adopted Maybach engines. This is indeed a wonderful tribute to that engine. Its weight per horsepower is considerably heavier than most aviation engines, but the Germans seem to have neglected that characteristic and demanded primarily reliability which, after all, is the first requirement that should be considered in aviation engines. From the data available it appears that only two airships, the LZ-24 (L-3) and the LZ-59 (L-20) were lost due to engine failure.

Curves

The curves plotted show at a glance the complete development of the rigid airship.

The points for the Schütte-Lanz curves are inclosed in triangles and the curves are light dotted lines. It is evident that the Schütte-Lanz airships followed the Zeppelin types and that the latter were the more important. For that reason the following comments will only refer to the Zeppelin types. (Points shown on curves as

squares and circles, curves are heavy full lines.)

At the extreme top we have the year in which the first airship of a particular type appeared, and next the LZ number of that ship. In the third heading are given the type letters arbitrarily assigned to the various classes of ships. Where several types have included in them airships which have different characteristics, these have been plotted separately on each curve (see H, H′, H″; P, P′; and R, R′, R″). For instance, the airships H, H′ and H″ are all of the same particular letter type, but since their characteristics varied and showed development within the type, it was necessary to plot them separately, as shown on each curve.

The first curve covers the percentage of useful load to total load and the figure shows an improvement from 20 per cent in 1900 to almost 70 per cent at the close of the war. In the second curve, the speed rose from 20 to 82.8 miles per hour. More than half of this increase was obtained in the period of 1914 to 1918.

The curve showing horsepower per 1000 cu. ft. (an arbitrary relation for purposes of comparison) indicates that the first Zeppelin was considerably underpowered, having only .07 hp. per 1000 cu. ft., wheras .7 hp. per 1000 cu. ft. appears to be an average figure. The influence of

the horsepower per 1000 cu. ft. on the speed curve is shown by the parallel fluctuations of each curve. Comparing types S, T, U and V with type R, it is noted that the hp. per 1000 cu. ft. fell from .742 hp. to .610 hp. per 1000 cu. ft., whereas the speed remained practically constant or even advanced. (R = 62.2, S = 60.3, T = 60.3, U = 66.0, V = 67.0 miles per hour.) This would indicate a better aerodynamical form in these later ships. The next curve is for total horsepower and this curve parallels more or less the following one, capacity in thousands of cu. ft.

The diameter curve shows few changes, mainly because of the stress of wartime production, since a change in diameter probably meant the scrapping of a considerable amount of dies and tools. This supposition appears to be borne out by the fact that in the commercial airship Bodensee, which, of course, is smaller than those produced at the end of the war, the Zeppelin designers returned to a diameter of 61.3 ft., which had been used on the 34 airships of the P and Q types. The next curve is for length and shows, as does the diameter curve, a steady increase up to the close of the war.

The curve showing the number of cells illustrates perhaps best the method of the Zeppelin engineers in the development of their airships. The method obviously was to construct a given type of airship, and when all information had been gained from it, cut it in two, insert an extra gas cell, and experiment with the lengthened ship. The next step was a redesign, either keeping the same number of gas cells or reducing them, and at the same time increasing slightly the length of ship and the horsepower, and, less frequently, increasing the diameter. The new product then is used exactly like its predecessor, and gradually better constructional features are developed and incorporated. The last graph indicates clearly the numbers of each type built, those built before the war, the successful war types M, P, Q, R and V and the experimental war types, of which only a few were built.

Type Y is interesting because it is the commercial airship Bodensee and has incorporated in it the experience of twenty years of airship building. Commercial transportation was financially successful in Germany before the war, since four airships made 761 flights for a total of 1713 hours, traveling 95,848 miles, carrying 13,917 persons in the period from 1910 to 1912. The improvement in the Bodensee airship of 705,000 cu. ft. over type E, a ship of nearly the same size, is no-

ticeable. Whereas Type E has a useful to total load percentage of 30.7, the Bodensee has 45.6, this all the more remarkable when the power plant increase of 600 hp. (from 360 to 960 hp.) is considered. This increase in horsepower represents a considerable increase in fixed weight which, of course, lessens the useful load for airships of the same capacity. As might be expected, the speed increases from 35.7 to 82.8 miles per hour. This increase is not entirely due to increase in power, but is due in a great part to the streamline form of the hull, and, from an aerodynamical standpoint, it probably is the best airship that has ever been built.

Of the first 22 (LZ-1 to 22 included) airships constructed, ten were used by Zeppelin or commercial companies, ten were taken over by the army, while only two were assigned to the navy. The army and navy divided equally the next 52 airships (LZ-23 to 74 inclusive) and of the remaining 40 airships, the navy secured 36 (excluding six for the navy on which building was discontinued), whereas the army only had four assigned. (The army received 12 Schütte-Lanz airships against the navy's 8.)

The Allies, from the table above, are credited with the destruction of a total of 40 rigid airships, of which 16 were shot down, 17 were hit by gun fire and subsequently wrecked, and 7 were destroyed by aviators in their sheds.

It may also be concluded from the table that forced landings are serious affairs for large rigid airships and generally result in wrecks. A total of 31 rigid airships were wrecked either through forced or bad landings. Further, 28 rigid airships caught fire either in their sheds, after being wrecked or in flight. It therefore appears reasonable that the use of helium instead of hydrogen would reduce the risk to personnel considerably as well as that of loss to a commercial company.

In regard to Item 2 of the "Conclusions" Table, all army airships (LZ—No. 26, 42, 57, 58, 63, 67, 68, 71, 73, 77 and 81) in use January, 1917, were ordered to be dismantled owing to the fact that it was decided to abandon airship operations conducted by the army. Two reasons can be assigned to this decision. First, the navy had personnel available for airship work, since the fleet was more or less confined. Second, naval officers were probably better trained to operate ships of the air, particularly in their navigational ability. The decision to abandon army airship operations probably was made in January, 1917, since the last army airship was

put in service Jan. 31, 1917, and the army airships were dismantled in the period from June to September, 1917. (One in February, 1917.)

Historical

The LZ-104, Naval L-59 airship, made a non-stop flight from Jamboli, Bulgaria, to German East Africa and back. The flight started Nov. 21, 1917, at 8 a. m. and there was a crew of 22 men on board, carrying besides gasoline, about 20 tons of medicines, bandages and special munitions, which were to be delivered to the German defenders of East Africa. Khartoum was reached when a wireless order was received ordering the airship to return because East Africa had been occupied by British forces. On Nov. 25, at 8 a. m., after a 96-hour flight, they landed at Jamboli, with, it is claimed, enough fuel, etc., for an additional 64 to 80 hours' run.

The R-34 crossed the Atlantic in July, 1919, taking 108 hours to make about 3600 miles or 5760 km. The Germans claim that the L-59 traveled on its East Africa trip about 1000 to 1500 km. further than the R-34, made it in less time, did not have the benefit of a meteorological service, had the additional difficulty of crossing the equator, which meant loss of gas due to valving, and that all in all the L-59 made a much more creditable showing. They further state that although the capacity of the L-59 was 450,000 cu. ft. greater than the R-34, the dead weight of this ship was 23,000 lb. less than the R-34.

The R-34 is more or less a copy of the LZ-76 (L-33), which was brought down at Brentwood, England, in September, 1916. When the LZ-96 (L-49) was brought down in France in October, 1917, it was examined with care and many of the later technical developments of this airship were incorporated in the R-34. It is, therefore, reasonable to give some credence to the above, for the English were undoubtedly unable in their first attempt to produce an airship holding a useful to total load percentage of 50.0, which the Germans claimed for the L-33.

As a matter of interest, it is estimated that the LZ-113 (Navy L-71) airship with a high speed of 82 miles per hour, and full useful load aboard could make a non-stop flight of about 11,160 miles, or approximately three times the distance from New York to Hamburg.

At the time of the signing of the Armistice the Zeppelin company had projected a monster airship (L-100) of 3,810,000 cu. ft. capacity, 780 ft. long, 96.4 ft. diameter, 10 engines 260 hp. each, which would have a high speed in

German Zeppelin Air

Maybach	240	1200	4 Jaray-LZ	67.0	Sept. 1, '17	Oct. 20, '17	1.7	V	Hit by gunfire in attack on England, wrecked at Tiefenort (Werra)

excess of 82.8 m.p.h. and a useful load in excess of 180,000 lb. with a total load of 259,000 lb. These weights give a useful to total load percentage in excess of 69.5. It had a maximum altitude of 26,900 ft., which compares with 6600 ft. for the LZ-24 (L-3) and 21,600 ft. for the LZ-113 (L-71).

Recent Aeronautic Features in Foreign Countries

SOME interesting comment has been given recently in regard to certain recent features of aeronautic development in European countries.

The London Daily Mail of April 14, 1921, contains the following, prepared by Harry Harper, technical secretary of the Civil Aerial Transport Committee:

"A vista so wonderful that our whole conception of the place of aircraft in the scheme of transport may have to be altered. Such is the promise of the new 'pulsating' wing of the Austrian scientist, Professor Raimund Nimfuhr. . . .

"The theory on which Professor Nimfuhr has been working is that we should concentrate attention on the propulsive methods of birds and insects. Aeroplanes with fixed wings and an engine driving a propeller can, according to this line of research, be shown vastly inferior in relative performance to either a bird or an insect.

"If one could take a bird like an albatross and increase it in size till it was as big as a medium-sized present-day biplane, it would, it is claimed, exert not more than the equivalent of about 10 hp. in propulsion, whereas the biplane would require about 200 hp. A giant gnat, big as an aeroplane, it is averred, would fly with infinitely less exertion of power than is required for any of our existing machines.

"The Nimfuhr principle is to imitate mechanically, so far as it is possible to do so, the methods of Nature, in the wings of birds and insects. The Nimfuhr 'pulsating wing' relies upon an extraordinarily rapid vibrating or stroke action upon the cushion of compressed air which in flight is formed beneath a sustaining plane.

"The actual Nimfuhr wing, as constructed, for a full-sized machine, will, it is understood, be hollow, with a flexible membrane on the underside. By pneumatic mechanism this membrane is set pulsating or vibrating with such rapidity that waves of atmospheric pressure are generated, which shall, it is intended, not only

sustain but also propel the machine. Air screws will, in fact, be eliminated."

Writing in the London Observer, April 17, 1921, Major C. C. Turner, R.A.F., states in part:

"Dr. Nimfuhr's 'solution' of the problem of soaring flight by means of a pulsating wing has yet to be proved scientifically sound; and, if that, mechanically expressible.

"At the moment the principal and most promising flight mechanism outside the aeroplane appears to be the helicopter, and especially some combination of helicopter and aeroplane. Some difficulties at one time supposed to be insuperable are no longer considered even formidable; and so convincing are the claims of helicopterists that both the British and the French governments have given financial aid for experiments. In England Mr. Louis Brennan of monorail fame, has been experimenting for years in the full confidence of the Government.

"It used to be supposed that even if vertical ascents proved feasible, the question of lateral motion by the same machine still had to be settled This difficulty appears to have been overcome by the simple operation of slightly inclining the screws, so that instead of rotating on a vertical axis their thrust is a few degrees from the direct downward. High speed in a horizontal direction is then attained."

*First airship of its type. †LZ-115 to LZ-119 not built.

Below is given a summary of the ultimate disposal of all rigid airships built by Germany.

Disposition	Zeppelin	Schütte-Lanz	Totals
1. Dismantled—Obsolete	11	5	16
2. Dismantled—Army Airship Operations Abandoned	11	2	13
3. Shot Down in War	15 (a)	1	16
4. Hit by Gun Fire and Wrecked	17 (b)	0	17
5. Wrecked, Storm, Forced Landing, etc.	12	3	15
6. Wrecked, Bad Landings, etc.	11	5	16
7. Destroyed in Shed by Fire	14 (c)	3	17
8. Destroyed While Handling on Ground	4	0	4
9. Destroyed by Fire in Flight	4 (d)	2	6
10. Turned over to Allies	7 (e)	0	7
11. Wrecked Deliberately Since Armistice	7 (f)	0	7
12. Building Discontinued	6	1	7
13. Now in Commission	2 (g)	0	2
Totals	121	22	143

(a) One shot down by aviators.
(b) Two burned after wreck.
(c) Seven destroyed due to aviator's bombs.
(d) Two fell burning, cause unknown; one hit by lightning.
(e) Two each for England, France, Italy; one for Japan.
(f) All wrecked in sheds deliberately to evade Peace Treaty conditions.
(g) Bodensee and Nordstern, LZ-No. 120, 121. Allied Commission claims these as replacement for (f).

The summary below divides the rigid airships into groups according to owners.

	Zeppelin	Schütte-Lanz	Totals
Civilian	12	1	13
Army	40	12	52
Navy	63	8	71
Building Discontinued	6 (a)	1 (b)	7
Totals	121	22	143

(a) Naval airships.
(b) Army airships.

ships (Rigid)—Continued

All the machinery is carried in the latter. There is a passenger deck with space for staterooms, dining-rooms and so forth, for passengers and crew. The envelope and the chassis are built in sections so that the airship can be enlarged. The airship is to be fitted with what is called the three-chamber system, using hydrogen, nitrogen and air. This is the device that provides protection against explosion, ignition and lightning. It is reported to reduce the loss of lifting gas (hydrogen) due to diffusion to 1 per cent as compared with other systems.

"The airship is to be fitted with a new propeller system which should make it possible to use all the dynamic forces of the vessel for forward, upward, backward and downward drive. Not the least important result, it is hoped to obtain from this equipment, is that of reliable landing without assistance from the ground.

"The hydrogen in the envelope is separated on all sides from the atmospheric air by a wall of nitrogen; these are the means used to eliminate the danger of fire. Should the outer envelope catch fire the flame, it is claimed, will be extinguished by the nitrogen

The Holland correspondent of the London Times reported March 30:

"Mr. A. Boerner, a Dutch airman, has invented a new type of airship, for which it is claimed that it needs no ballast and is not subject to loss of gas. More important than either of these is the claim that in the Boerner airship the danger of explosion is eliminated.

"Briefly, the design of the airship is as follows: The balloon proper consists of a large number of individual gas cells attached to a bridge chassis made of duralumin.

escaping as soon as a hole is burned in the envelope.

"The Boerner airship is about 950 ft. long and is to be propelled by 32 gasoline engines, to each of which an air screw is attached. The total horsepower developed will be 6400. On half its power the airship is to fly at a speed of 72 miles an hour. By the Boerner system the air screws may, together or in groups, be adjusted so as to propel the airship in any direction. The suggested number of passengers that the airship will be able to carry is 300."

Development of Aircraft Tires and Wheels

McCOOK FIELD Air Service Engineering Division activities in the rubber materials used in aircraft construction have been mainly centered around the development of the straight side tires and wheels. A satisfactory program of wheel and tire sizes has been drawn up after considerable experimental work, and it is hoped that tire and wheel replacements will be of the straight side type, rather than of the present clincher type.

Experimental work on the development of straight side tires and wheels has extended over a period of about two years. The chief reason for an attempt to develop the straight side tire has been that the unsatisfactory performance of the clincher type was most marked in the case of the DeHaviland airplanes, which use the 750x125-millimeter tires.

At best, the clincher tire has never been satisfactory, even in the case of automobiles, except in the smallest sizes. Underinflation was the chief contributing cause, as the majority of the trouble experienced was due to rim cutting. A secondary contributing cause was the type of wheel used, which is essentially an unbalanced structure.

The first service test on the straight side tires was made with the 44 x 10-inch tire, used on the Glenn L. Martin airplane, of the type which has only two wheels. To date the performance of these tires and the service, which extended over a period of about six months, has been very satisfactory.

Another size which has been subjected to service conditions is the 36 x 8-inch tire, which was developed with a view to replacing the 900 x 200-millimeter size. An essential difference between this size and the 44 x 10-inch size is that the wheel for the 36 x 8-inch tire has a one-piece rim, having a channel in the center to permit of the application of the casing. In general, it resembles a type of rim used on the Fokker D-7, which was equipped with a straight side tire. The wheel for the 44 x 10-inch tire has a truck-type rim. This includes the removable side ring to permit of ease of application or removal of the casing.

In every case of straight side tires the wheel used has a hub which is centered in the wheel, as opposed to the Palmer type of off-set hub. Other sized tires are being manufactured for service test, and it should not be long before complete information is available regarding the suitability and serviceability of this type, as compared to the original clincher type. It is believed that the difficulties experienced with the clincher type tires, especially when used on the Palmer type wheel, will be completely overcome in the straight side tires.

Automotive Demands Give Strong Impetus to Drop Forging Development

"The automotive industry was one of the first to appreciate the advantages of drop forgings," said an executive recently. The extent to which technical drop forging practice has been influenced by automotive demands is a phase of relations between the two industries discussed.

THE automotive industry has not only achieved very rapid growth itself during the last decade, but has been the cause of very marked technical and commercial development in certain contributory industries. One of these which has profited largely from its contact with the automotive field is the drop-forging industry.

The drop forge industry in the United States has had two major booms during its long existence. Drop forgings have always been used extensively in connection with firearms and ordnance, while they have been utilized also to some extent in railroad work and more recently in shipbuilding. The first real boom, however, was caused by contact with the bicycle industry, which attracted so much attention about twenty-five years ago. Next the automobile industry started its great rise.

Technical Development

To this latter contact can be traced a large percentage of the recent technical growth of the drop forging industry. The development of new methods has been very rapid during recent years and has been inspired chiefly by the demands of the automotive industry. The development of crankshaft manufacture may be cited as an instance of this development. Automobile and truck makers have been demanding an increasing accuracy in the manufacture of this part. As a result the drop forgers, through extensive experimentation and intensive research, have succeeded in meeting that demand. The same thing is true to a large extent of almost every drop forged part used on cars and trucks.

As the demands grew, many progressive drop forge concerns began to try to anticipate future demands, that they might be ready to meet requests as soon as they were made. Consequently, it has been possible for drop forgers on occasion to present to the automotive industry new methods for making better and more accurate forgings from time to time.

Drop forgings, of course, compete directly with malleable and steel castings in selling to the automotive industry. For this reason the drop forgers have made considerable effort in individual cases to study the possibilities for an increased use of forgings on cars and trucks; to devise new forging methods to meet automotive needs, with the idea of attempting to replace castings in certain instances.

Up to the present time, however, the demands upon the drop forgers have been so great that they have been kept busy to a large extent keeping pace with the demands made upon them, to the detriment of this experimental and research work. One prominent drop forge executive says, for instance, that:

"The general opinion seems to be that during the last few years the development along this line has not been carried on because of the high production requirements in the regular line, but since the dropping off in production has come about there is a very great effort being made along this line."

Such research is directly in line with the most urgent needs of automotive manufacturers at the present time. Reduction of production costs is necessary and material assistance can be rendered by a contributory industry such as this by research and experimental work.

Drop Forging Characteristics

Taken in a general way, the drop forging has always possessed certain characteristics which made it specially adaptable for automobile and truck construction. Some of these qualities, familiar to engineers, may be listed as follows:

1. Comparatively great uniformity of quality: not subject to certain defects, such as blow-holes
2. Suited to quantity production methods
3. Tensile strength and percentage of elongation in given length practically always high enough to meet requirements, even though highest grade steels or alloys are not used
4. Uniformity as to thickness, etc.
5. Possibility of producing forging to very close tolerances, thus necessitating a comparatively small amount of machining. The ordinary drop forging can be produced to a tolerance of 1/32 in., but many forgings are now being produced to smaller tolerances

One of the chief drop forging developments for which the automobile industry is largely responsible is in connection with the handling of high efficiency steel and new alloy combinations. As a result of efforts along these lines drop-forging operations are possible to-day that were considered utterly impossible fifteen years ago.

Limitations of Practice

Although remarkable strides have been made in drop-forging practice to meet the requirements of automotive engineers, there are limits to what can be accomplished. Discussion at the convention of the American Drop Forge Association during recent years indicates that engineers and designers sometimes make their design entirely from an engineering viewpoint without considering the limitations of drop-forging practice, even though they expect to use drop-forgings in construction.

One drop-forging manufacturer expressed it this way: "Drop-forgers should be called in for consultation and advice when new designs are being worked out. Or at least preliminary drawings or sketches should be sent to prospective sources of supply to get constructive suggestions and to avoid the revising of completed designs and details. Many drop forgers are more than willing to render their services to their regular customers, if not to the trade at large, and in many instances the saving has been enormous."

There is obviously an excellent field for co-operation along this line, since it is readily conceivable that considerable expense may be saved the manufacturer if, in making a design, he takes into consideration the limitations of drop-forging practice.

Co-operative Possibilities

In connection with the possibilities for profitable co-operation between the designer and the drop-forger the following statement recently made by a member of the drop-forge industry is of interest.

"There is no question but that the average automobile engineer and designer should be very well acquainted with the difficulties encountered in making drop forgings, in order to design forgings to the best advantage. There are a very large number of forgings made the production of which cause a great amount of trouble, and which can be produced only at a very high cost.

"This trouble and extra cost is made necessary through ignorance of the designing engineer of the fundamental principles of drop forgings. If the designing engineer had known the way in which forgings of a similar design were made, the design of the parts in question could have been simplified so as to render the forging easy to make, and at the same time capable of serving its purpose just as effectively.

"The general trend among automotive engineers, however, is to work more closely with the drop-forge industry in the designing of important parts, so that such difficulties can be eliminated and the best part for the least cost be produced."

While most of the progressive drop forge concerns are ready to render such co-operative service, the car designer and engineer has not always been satisfied with the kind of help extended. One prominent engineer, for example, complained recently that his experience had been that the drop forgers in making suggestions for simplification for manufacture did not take sufficiently into account the desire of the designer for individuality and other similar factors.

It must be admitted, moreover, that the drop forgers have not attempted very extensively, except in a few individual cases, to bring directly before the automotive engineer the various features and possibilities of their practice. An investigation of the situation indicates that very little sound publicity work has been done along these lines by drop forgers in general. It would seem that a definite attempt to reach directly the automotive engineers with information of this kind would increase the possibilities of mutually helpful co-operation.

Drop Forging Process

The details of drop forging practice cannot be adequately described, of course, in a brief article, but certain essential features can be outlined which will be of general interest. The process of drop forging is more complex than is sometimes understood; it consists of far more than merely heating metal and hammering it between dies. As one authority says, "The production of high grade forgings is, in reality, a co-ordination of many functions carried through with a nice regard for their effect upon one another."

The first factor of importance is that of chemical analysis and heat treatment. The chemical properties of any given lot of steel are a fixed quantity, but the physical properties can be changed by the application of the proper heat treatment. The amount of change possible by heat treatment, of course, is limited to a certain extent by the chemical analysis of the particular lot.

In the actual forging process several sets of dies are used. One set is used for forging, one set for trimming, and other sets for punching and bending. A properly constructed and sufficiently strong die is the chief essential of successful drop-forging. The value of a die from the point of view of the forging buyer should be judged rather in accordance with the quantity and quality of the forgings produced from it than with the actual initial cost of the die itself. One of the prominent forging concerns says that "the best dies cost anywhere from three to five times what poorer grades cost, but they are always cheapest in the end. A die made from good steel, carefully hardened and finished to a high polish, will make more forgings than a cheap die and will make them better."

The making of dies is a difficult job requiring the highest skill in workmanship. The various steps in constructing a die may be listed in general as follows:

1. The die block is planed smooth on the impression side, and the opposite side is cut a key, which holds the block in place on the ram or in the sow block of the hammer
2. The impression side is thinly copper plated and the outline of the forging is etched through the plating
3. The rough impressions are cut out on a mill or lathe
4. The die is finished by expert hand tooling

When the finished impression has been sunk in the die, a sample cast of Babbit metal is obtained, by means of which the general outlines of the piece can be checked up and suggestions made for changes before the die is finally finished to accurate dimensions.

The next step is to select stock of the shape which can be handled and forged most economically. Billets, round and square bars, or flats, are ordinarily used. There is a distinct danger of choosing too small a bar in an effort to reduce the amount of waste. The size of the stock should be large enough to permit the metal to be worked clear through and not merely on the surface.

There are four different operations on the piece while actually under the hammer:

1. Edger
2. Break down
3. Finishing pass
4. Cut off

A certain amount of excess stock, known as the flash, must always be removed from the forging after it comes from the hammer. This is the trimming operation. Trimming is followed by cleaning, after which the heat treatment takes place, provided this is to be done at the forge shop.

Difficulties

Certain definite difficulties present themselves in drop-forging practice. Every forging is not perfect, of course, even though the best manufacturing methods be adopted. A large proportion of defective forgings can be traced to defective dies. Some defects, such as laps, are superficial and do not affect the quality of the forging, but others are more serious. Among the chief possible defects are checks, laps, excess stock, scale pits, round corners, burrs, pipes and seams.

In a high grade shop, of course, forgings with such defects never get outside the forge shop. They are of interest to the customer chiefly since his design and demands sometimes affect one way or the other the possibility of producing a high percentage of perfect forgings.

Work of Drop Forge Association

The American Drop Forge Association comprises about 68 per cent of all the drop forge concerns in the

country and probably about 90 per cent of the total tonnage produced each year. This association has interested itself in the quality of the work done by its members, although the results of this interest are not recorded in definite statistics.

The Drop Forge Association has from time to time studied and compiled various tables of standard tolerances of drop forge practice, both with regard to dimensional limits and the weight limits of various types of forgings. The association uses the S. A. E. standard specification for forgings and attempts to see that all the forgings produced by its members are held well within those limits.

While definite figures are not available, a careful estimate states that fully 90 per cent of the output of the drop-forging industry has been absorbed by automotive manufacturers during the last five years.

The Drop Forge Association has not, as a body, undertaken anything in the way of research work up to the present time. The statement is authorized from a responsible source, however, that work of this kind, similar to that being done by the American Malleable Castings Association, is likely to be taken up and carried forward in the very near future.

One reason that records are not available to show the increased quality of the physical characteristics of forgings over a period of years is that a large percentage of the forgings produced by members of the Association are supplied to automotive manufacturers with no final heat treatment. Several individual members of the Association, however, have built up very strong laboratory and research forces and have carried work of this kind to a very high state of development. These standards are really considered by the rest of the industry as the standards for automotive work.

The recently formed American Drop Forge Institute is an association of the executives of the various drop forge companies designed to further the general interests of the drop forging industry along broad and constructive co-operative lines.

The Association has dealt entirely with practical shop problems, but the Institute will concern itself with the broader aspects of the industry, such as the relation of the drop-forging industry to outsiders with whom it comes in contact, uniform cost methods, the possibilities of constructive research, and so forth. It will have nothing to do with prices in any manner whatsoever, either directly or indirectly.

The Institute has been formed so recently that only these broad outlines of its purpose can be given at this time. Whether both the Institute and the Association will continue permanently or whether the Association will be merged into the Institute will be decided by the future.

The accompanying list includes the parts of a four-cylinder car which are made from drop forgings. This list is reprinted from AUTOMOTIVE INDUSTRIES of Jan. 20.

While additions might be made, the list is the most comprehensive that has yet been published and is included here for that reason.

Automotive Parts Made by Drop Forging

ENGINE

Crankshaft
Crankshaft counterweights
Crankshaft drive gear
Connecting rods
Camshaft
Camshaft drive gear
Rocker arms
Rocker arm brackets
Valves and stems
Valve lifter plungers
Valve lifter guide yokes
Magneto drive gear
Magneto idler gear
Generator drive gear
Generator strap tee, upper
Generator strap tee, lower
Pump shaft gear
Distributor drive shaft gear
Starting crank
Starter pedal
Starter pedal pad
Starter shaft lever
Starter operating shaft rod
Starter motor drive gear
Water pump drive gear
Oil pump adjusting shaft
Carbureter pipe flange
Throttle control lever
Spark control lever
Accelerator pedal
Fan supporting arm
Front motor support
Rear motor support

TRANSMISSION

First speed and reversing gear
Direct drive and second speed gear
Countershaft
Countershaft gear
Countershaft first speed gear
Countershaft second speed gear
Reversing pinion
Gear shift lever
Gear shifter shaft
Shifter rod
Shifter rod end
First speed and reversing gear and shifter fork
Direct drive and second speed gear shifter fork
Clutch pedal
Clutch pedal pad
Clutch pedal stop
Clutch throwout yoke
Clutch shifter lever
Clutch shifter shaft
Clutch spring sleeve
Clutch hub
Clutch drum
Drive shaft universal joint
Drive shaft universal joint flange
Drive shaft universal joint sleeve
Drive shaft universal joint sleeve yoke

RUNNING GEAR

Front axle
Steering knuckle, right
Steering knuckle, left
Steering spindles
Pitman arm
Steering arm
Steering yoke
Steering gear worm sector
Steering gear worm
Steering rod
Front spring shackles
Front spring plates
Front spring clip spacers
Rear spring brackets
Hand brake lever
Hand brake lever latch
Hand brake lever latch end
Hand brake tube rocker arm
Hand brake cross shaft levers
Hand brake cross shaft rocker arms
Hand brake cam levers
Hand brake levers
Hand brake lever clevis
Foot brake pedal
Foot brake pedal pad
Foot brake cross shaft rocker arms
Foot brake cross shaft levers
Foot brake operating lever
Foot brake band adjusting clevis
Foot brake band links
Brake equalizer draw bar
Brake equalizer draw bar clevis
Brake control turnbuckles
Brake pull rod clevis
Front brake band lever clevis
Torque arm
Torque arm pillar
Differential gear
Differential pinion
Differential pinion spider
Differential driving gear
Differential driving pinion
Rear axle nuts
Rear spring shackles
Rear Spring plates

ACCESSORIES

Windshield side arms
Tire carrier arms
Toe bolts
License tag clamps
Top support adjusting brackets
Top support wing bolts
Gasoline tank strap draw bolts (front)
Gasoline tank strap draw bolts (rear)
Valve tappet wrench
Valve tappet adjusting screw wrench
Valve lifting tool
Water pump stuffing nut wrench
Exhaust manifold packing nut and differential bearing adjusting nut wrench
Crankcase main bearing bolt and flywheel oil plug wrench
Spark control and oil reservoir drain plug wrench
Rear axle pinion shaft bearing gage

The FORUM

Concerning Argentine Trade

Editor, AUTOMOTIVE INDUSTRIES:

You, of course, realize that as you are just entering upon your spring season we are entering upon the fall and our winter season will not be over until the end of September. Consequently, our best months for selling automobiles are now about over and the new season does not begin with us until September or October.

The season just now closing has not been, generally speaking, a satisfactory one to the automobile trade. The unsettled and unfavorable conditions which have been existing in Europe, Great Britain and the United States for the past several months have reflected themselves very seriously in this market, and business in most lines has been almost paralyzed. Taking our automobile season as from Sept. 1 to April 1, I do not believe that during the season just closed there were more than 33 1/3 per cent of the quantity of cars disposed of the previous season sold. During the past three or four months such demand as has existed has been confined to a very few well-known cars which have become well established here and are being handled in a proper manner. From such information as I have been able to gather through our own organization and from outside sources, I am sure that we have been selling more cars than has anyone else, with the exception of Ford. The sale of the Ford has also fallen off a very great deal. Our business this year has probably reached more or less half of what it was a year ago, but it is to be borne in mind that a year ago we were not able to get sufficient cars from the factory to fill our requirements, and I do not know to what volume the business might have run had we been able to keep in stock.

You have no doubt seen press cablegrams concerning the number of cars and trucks in the Buenos Aires Custom House, most of which reports, I think, were exaggerated, and I believe you may, therefore, be interested in knowing the facts. The Association of Automobile Importers in Buenos Aires sent some of their own employees to the Custom House to take count of all the cars and trucks deposited there and they give the total as 2003. This count was taken on March 25. This is not a large stock for normal times, but under present conditions it is excessive and will undoubtedly take a great many months to liquidate. We, fortunately, were foresighted enough last September to alter our orders to bring them more in line with the anticipated demands, and, as the General Motors Export Co., understanding perfectly the existing conditions here, co-operated with us in a very whole-hearted manner and relieved us of the possibility of having an excessive amount of cars shipped to us, our position, therefore, at the present time is very comfortable in this respect. This is, unfortunately, not true of several of the other automobile agents here, some of whom are carrying a very heavy burden, and a few houses have been forced to liquidate their automobile business and in some instances left a few cars on the hands of shippers.

The Association of Automobile Importers also furnishes me with the following figures concerning the importation of automobiles and trucks during the months of January, February and March of this year:

From the United States, imported during these three months, 296 passenger cars and three trucks; from Great Britain and Europe, during same period, 66 passenger cars and 28 trucks.

You asked me how I am estimating the 1921-1922 season for the automobile business in the Argentine. I am afraid that I cannot make satisfactory reply to this question. I think it is too early yet for anyone to even guess with any degree of accuracy, and I have not attempted as yet to make any plans for next season. In July or August we should be able to form some idea, but even then one will not be able to prophesy with accuracy. We cannot tell a great deal about the prospects of next year's crops before August, and a great deal depends upon the movement of the hides, wool and cereals which are now available for export and in which there has been practically no movement for many months. Until these products move freely for export I see no possibility of any material improvement in either financial or trade conditions here, and it is impossible to say when this hoped-for movement in exports will begin. I am very much afraid that this calendar year is going to be one of liquidations very largely, with a possibility of some material improvement in conditions during the last quarter.

I wish to thank you very much for writing me, and I shall be very glad to hear from you personally at any time that you have the time and the disposition to write.

WILLARD T. CLARK,
Henry W. Peabody & Co.

Buenos Aires, April 8, 1921.

Volumetric Efficiency vs. Fuel Economy

Editor, AUTOMOTIVE INDUSTRIES:

Referring to your editorial in AUTOMOTIVE INDUSTRIES, "Is Volumetric Efficiency of Prime Importance?" issue of April 28. The last two paragraphs clearly define the effects and differences due to proper application of heat to the charge compared with the lack of sufficient heat. It is surprising that the oft-repeated argument against the application of heat on account of its tendency to reduce volumetric efficiency still continues to be put forward.

There is no question but that this is a complete fallacy, not only by reason of the fact that only 10 per cent of the time is the average passenger car engine called upon to exercise its full output, but also that this possible lack of volume, due to pre-heating of the charge, is greatly offset by the more rapid and better combustion that results from its proper preparation.

As a matter of information, it should also be pointed out that the heat taken up by the charge at full loads is greatly reduced. With wide-open throttle, the maximum temperature of the mixture occurs at the lowest speed, being rapidly reduced as the speed increases. At part loads the volume of the mixture passing through the

manifold is so small, comparatively, that the heat taken up increases, despite the fact that the external temperature of the manifold may not be as great as at wide-open throttle.

The popular conception of the heat of the charge is gained as a result of the observation of manifold temperatures, neglecting the question of heat units which can be absorbed by the mixture, which depend on volume and velocity.

We demonstrated, several years ago, with two motors identical in size and construction, with the exception of manifolding, that it was possible to obtain more torque at any speed and a greater maximum horsepower with the heat than without it, while, of course, the fuel economy was infinitely superior with the heated manifold.

There are many owners of cars, who, during the colder months of the year, use them for business purposes, probably for very short distances, and it is under these conditions that the proper heating of the charge is appreciated. Without it the engine does not run sufficiently long to function at all properly and requires constant manipulation of the choker, with its attendant ill results. A. A. BULL, Chief Engineer,
Northway Motor & Mfg. Co., Div. Gen. Motors Corp.

The Efficiency of Weak Mixtures

Editor, AUTOMOTIVE INDUSTRIES:

The whole automotive world must feel deeply indebted to the Asiatic Petroleum Co. for providing the necessary finance to enable Messrs. H. R. Ricardo, H. T. Tizard and D. R. Pye to conduct the extremely accurate and valuable research which has now been proceeding for more than two years in England.

Among the mass of information already given to us there is one phase which, to me at least, is of the first interest by reason of its having occupied my firm devotion for many years. This is the pronounced attitude of the findings in favor of the adoption of weak mixtures, if this can be done commercially.

Quoting from the reports: "The conclusion to be drawn is that the indicated thermal efficiency of the best engines is not likely to be improved upon substantially by any development of design other than that of the employment of weaker mixtures than can now be used . . . our results show that great improvement is to be expected."

The report appears to advocate at least a 20 per cent weaker mixture than that which is theoretically correct, and states that, with a very weak mixture, ignition is only possible by the stratified charge or similar arrangement. The reason for this is that "a homogeneous mixture of fuel vapor and air cannot be exploded if the concentration of the fuel vapor is appreciably less than 80 per cent of that required for complete combustion of the air."

Discussing the question of dissociation of CO_2 with a 20 per cent weak mixture, the report states that "at the lower temperature at the end of the expansion stroke the dissociation is negligible. The work done by the expansion in such a case is practically the same as if no dissociation occurred; in fact, the only effect of dissociation is to lower the maximum temperatures and pressures without materially altering the efficiency." Mr. Ricardo shows how, with a compression ratio of 5 to 1, he reaches a critical maximum with one fuel, so that if the compression is raised and the mixture strength remains the same, detonation occurs unless a slower burning mixture is used. He prefers to do this by either retarding the timing of the ignition or by *enriching* the mixture on test, although he says that the same results could be reached by reducing the mixture strength, but states the fact that the range on the weak side is very limited, "so narrow, indeed, that to attempt to escape detonation by working entirely on the weak side would be completely out of the question in any practical multi-cylindered engine, on *account of irregularities in distribution.*"

The italics drawing attention to the last phrase are my own. The report makes out a strong case in favor of the line I have followed. I have conclusively proved that the weak mixture can be used commercially and that it does reduce detonation. In 1912-13 I built several cars and had tests made by the Brooklands Racing Club on speed. One touring car of about 3000 lb. weight consistently did 26 miles to the gallon of fuel when adjusted for racing and hill climbing, and was certified doing 77.02 miles per hour on the track with the same setting.

The only way that such mixtures can be used commercially in an ordinary engine is by overcoming the distribution problem, and this is what I set out to do. I need scarcely point out the importance of every cylinder performing the same amount of work as its neighbor and in a similar manner. This is more important than engine balance from a mechanical point of view, but a fact often overlooked. I attacked the problem by eliminating the disturbing elements from the vapor stream and allowing only a comparatively dry homogeneous vapor to pass into the manifold. This is done by a system of separation and application of local heat.

The temperature of the manifold is of considerable moment, and this was ably dealt with by Mr. Frank A. Howard in his paper before the S. A. E. last winter. He, however, bases most of his deductions on the supposition that the engine runs with an absolute manifold pressure of 0.5 atmosphere. This, of course, would be an advantage from the vapor pressure point of view. My system operates equally well at approximately atmospheric pressure, tests being invariably made at low engine speeds and full throttle opening, a difficult condition for carburetion.

Recent examinations, made by an independent chemist, of exhaust gases from a large four-cylinder engine running on a mixture strength of between 16.8 to 1 at 500 r.p.m., full load, and 16.2 to 1 by weight at 1000 r.p.m., on full load and half load, showed that the combustion was complete in each instance. Mixture strengths of 17.4 to 1 are satisfactorily used, and these weak mixtures will give rapid acceleration; in fact, as compared with the usual commercial set of carburetor and manifold, the Brewer system generally shows an increase in the rate of acceleration up to 33 per cent with a decrease in the fuel consumed for equal work of at least 20 per cent and sometimes as high as 40 per cent.

Examinations of glass manifolds invariably show that there is sufficient liquid on their sides to suffice for as much as 50 cylinder charges. How can one expect to have equal distribution when such a state of affairs exists? ROBERT W. A. BREWER.

Correction

On page 910 of AUTOMOTIVE INDUSTRIES of April 28 there was printed a letter from C. T. Myers on the subject of Hub Standardization, in which a sentence read in part:

"The Scotch have a gloomy way of regarding the efficacy of remedies that are not mixed in their own pharmacy."

Mr. Myers intended that this part of the sentence should read:

"The doughty Scotch at times have a gloomy way of regarding remedies that are not mixed in their own pharmacy."

The Meaning of the British Coal Strike

Prolongation of the British coal miners' strike may reduce to starvation a large proportion of the population. The momentum of an idea, such as British Labor has, may cause people to rush forward even to the point of destroying the very aspirations for which they are struggling.

By Harry Tipper

THE coal strike in Great Britain continues to drag along with no immediate prospect of relief and with an indication that the other unions are prepared to protect the miners at least to the extent of preventing coal coming into the country if their union orders can do it.

The efforts of the government and the leaders of other unions have failed to bring the mine owners and the workers together, and so far the pressure of public opinion has been unable to effect any basis for further discussion. The stagnation of industry brought about by this strike is very severe, and it will have its effect upon the prosperity of all workers for a considerable time after the strike may be settled.

Great Britain is primarily an industrial country. Its population is more largely industrial than any other country except perhaps Belgium. By far the majority of the workers are occupied in some form of industrial endeavor and as a consequence of this the majority of the working population are members of unions, industrially. Politically, there is a very strong body of socialism paralleling the strong industrial unionism. Despite the fact that the present stagnation of industry will bring a large part of the population to the verge of suffering, if not to actual semi-starvation, the business of forcing the political industrial problems to conclusions is going on and the working population are pursuing these actions, even though they may destroy their prospect of future prosperity for a number of years.

We are very much inclined to forget that the momentum of an idea strongly fixed in the minds of a number of people will rush forward, even though its movement destroys the very aspirations which are back of the adherence to the idea itself. For this reason, the tendency and growth of a new creed in business or politics is very important; more important than the logic of its definition or the justice of its idea.

In the long swing, all such movements tend to equalize themselves and secure a larger measure of justice for the general group, but the long swing in human affairs may involve several centuries. In the meantime, the pressure of strongly organized groups fighting for definite ideas to be put into practice, disturbs the fabric of industry seriously. This disturbance may destroy the efficiency of the industrial accomplishment to a large degree and reduce a percentage of the population to starvation or destroy them. The present coal strike in Great Britain is critical for that reason. It may not be possible to confine the strike to the dispute between the miners and the government as the stagnation of industry grows and the suffering increases.

A good many years ago there was a prolonged struggle between the foundry men and steel workers and the owners, which affected all the steel and metal trades industries in Great Britain. That strike lasted about nine months. The strike was called after repeated attempts at negotiation and as the result of a complete split on one or two of the matters involved.

During the first two or three months of the strike, the affected workers were quite orderly and no attempt was made to interfere in the operations of some of the companies who employed non-union men. As the time went on and the strike funds diminished, strikers began to suffer in considerable numbers. In some of the towns depending upon the steel industries, the condition of the population was very serious. Sporadic outbreaks occurred, and when the strike was finally settled, a good many riots and other difficulties had disturbed the peaceful character of the dispute.

During the same period a considerable amount of the business went over to Germany, Sweden and other countries and a good deal of capital was transferred to the building of steel plants, foundries and so forth, in those countries. For a number of years the effect of that strike was felt in the position of the British metal trades industries in competition for export markets.

Any large development of suffering from the present stagnation in Great Britain is likely to have its effect in increasing the unrest of the population very materially. The last report indicated that the number of unemployed had reached several million, and each week without a reasonable supply of fuel the number increases.

Distribution will be difficult, even the distribution of foodstuffs will become sufficiently difficult to require severe rationing if the struggle is prolonged. In that case, the bitterness must increase and the population become more and more inclined to take severe measures to relieve themselves of the hopeless situation. It is more and more apparent that the political questions in Great Britain are subsidiary in importance to the industrial questions, and the future position of the country depends very largely upon the settlement of some of these important basic industrial problems.

The Whitley Councils have been of advantage in the settlement of smaller disputes, in the relief from local grievances, and in the interpretation of rules concerning the conduct of the particular industry. All methods of adjustment have failed industrially to meet the situation when the national aims of the trade unions have been at stake and the political aims of the labor party have been concerned.

Developments in Great Britain will have a considerable bearing upon this country; the relation is

too intimate to permit us to be without interest in the matter; especially since upon the stability of the industrial fabric in Great Britain depends the stability of the European Industrial World.

If this strike can be settled by the weakening of the miners or by the reconsideration of the owners, and with reasonable promptness, the settlement and its character will indicate the tendency of labor opinion in regard to its own program and the methods taken to secure it.

If the strike is protracted and the country maintains its orderly condition, it will become evident that the labor party is concerned with pushing some of its political ideas to immediate adoption and that its power is greater than we suspected.

In any event, the coal strike indicates the critical state of political affairs in Great Britain and the character of its settlement will have an important bearing upon the future policy of the country. It is one of those visible disagreements which accumulate out of years of slow definition, and as such, is likely to indicate the character of future developments more definitely than previous discussions have done.

We were somewhat disturbed in this country when we had a few days with the miners out of the mines, not very long ago. There has been a complete stoppage of coal production in Great Britain for several weeks now.

The stocks are almost exhausted and the unions have put an embargo upon importation. The next few weeks should be critical and important.

Statistics, Necessary and Unnecessary

THE usefulness of statistics and compilations would seem to be the only basis upon which to test the advisability of getting them together. The average business man would regard as a lunatic an automobile executive, for instance, who paid money to an employee for collecting data as regards the number of women with blue eyes in the cities of less than 10,000 population. Yet there are many statistics compiled and many charts kept up to date in various business institutions that have little more actual, practical value to the management than the figures in the example to the automobile producer. As B. C. Moise, secretary of the National Tube Co., put it recently: "Necessary figures are indispensable; unnecessary figures are a pure waste, not only of money, but of what is more important, time and effort."

Along with this statement, Moise made some other very pertinent remarks in an address on "Cost Accounting" before the recently organized Industrial Cost Association. The part of his talk which touched specially on this subject of unnecessary figures is of special interest:

"*Costs should be as simple as it is possible to make them consistent with giving all the necessary results.* Necessary figures are indispensable; unnecessary figures are a pure waste, not only of money but of what is more important, time and effort. Unnecessary figures tend to confuse the man who uses the costs instead of helping him. I have known some cost men who seem to consider that the object of the cost system was to make figures and not to get results, and as a result they piled up meaningless masses of exhibits which nobody wanted and which nobody could use.

"It should be a principle of every cost department to make only costs which are clearly necessary for the conduct of the business for selling, operating or competitive reasons, and to make no other exhibits which are not asked for as necessary by either the selling or the operating organization. Also, care must be taken to weed out costs or exhibits which have lost their value due to the lapse of time, or which were only meant to serve a certain purpose. I think every large cost department which makes up exhibits in considerable detail should have a committee appointed whose business it would be to go over every single cost sheet, report and exhibit made, at least once every three months, with a view to eliminating those found no longer necessary or those which were not used. A detailed classification on a cost sheet, or a detailed exhibit, may seem admirable to a cost department and may have been urgently requested by an operating official, and yet after the first two or three reports be unused.

"There is no object except expense and confusion in making reports which are not used. It is often the case that an operating official will cling to reports and detailed exhibits that he never looks at. In some companies, not only are the reports gone over quarterly, but where the accounting official at the mill has reason to believe that the report is not used, it is quietly dropped, and many times, in such cases, the operating official never even notices its lack. It evident that such reports are only a cause of expense and confusion. I cannot too strongly insist upon the desirability of a periodic review by every company of all reports of every nature, with a view to the elimination of those which have served their purpose, are obsolete, or which are not used to an extent to justify the expense of preparation.

"It seems to be the fashion for the legislative bodies of the National Government and the several States, and also, I am sorry to say, for many well-meaning but misguided eleemosynary societies, to consider that all human ills can be cured by the excessive multiplication of laws and the excessive multiplication of detailed figures. The extent to which miscellaneous information of all sorts is demanded and collected by National and State Bureaus is truly enormous and alarming. As a rule, and I speak from long experience, these reports have very little value of any sort. The data is asked for by people who often do not understand the subject, who have had no training and who are actuated by well-meaning but misguided enthusiasm. That is the charitable view. The other view is that all these unnecessary reports require additional clerks and these additional clerks are not necessarily skilled and trained men, although their salaries add to the taxes which you and I and every corporation pays."

Trades Disputes in Great Britain

THERE were 1715 labor disputes in Great Britain during 1920, an increase of about 300 over the preceding year. The number of persons involved, however, was smaller during 1920 than during 1919. The total number involved in the 1920 troubles was 2,019,000 as against 2,586,000 in 1919.

In 1919 there were 34,903,000 working days lost because of these disputes, but in 1920 the total reached only 27,011,000. A study of the detailed figures as reported by the British Labor Gazette shows the coal miners to be responsible for the most important of these disputes. Nearly a million and a half men were involved in mining disputes; that is, over half the total number involved in all the troubles.

The engineering and shipbuilding trades which caused the loss of 10,000,000 working days in 1919 was responsible for only 2,500,000 lost days during the last year. The miners lost 17,424,000, however, bringing the total up within striking distance of the previous year.

Growing Popularity of the Line Drive

IN these days of hesitancy among potential tractor purchasers it behooves manufacturers to diligently study all possible means of making their machines more serviceable to the farmer. One feature that unquestionably makes a strong appeal to the average farmer is the line drive. It is not so much the sales phrase that it "handles exactly like a horse," but rather the saving in labor in certain farm operations. The harvest season is always a very busy time on the farm, and if a man is required to ride on the binder in addition to the man operating the tractor, it is a great handicap for the tractor. Although farm labor conditions have been somewhat relieved, the farmer is still under the influence of conditions that obtained during the past couple of years when efficient help was exceedingly rare and expensive and the other kind extremely unsatisfactory.

For operating a manure spreader, for hauling farm wagons and various other operations the line drive is exceedingly handy. The length of time the tractor is used for such operations may not be very long as compared with the plowing period, but the point is that the extra help required for these occasional operations is not available on the smaller farms.

That farmers think highly of the line drive idea has been demonstrated time and again at shows by the crowds at stands on which such tractors were exhibited. Line drive attachments have also been developed for the Fordson tractor and evidently met with considerable sale.

At first the line drive principle did not take well with the leading tractor makers, who evidently considered it a mere selling feature intended to convince the timid prospect of the ease of tractor operation. Its practical advantages are gradually coming to be recognized even by the more conservative makers, however, and the number of line drive models offered is perceptibly increasing.

New Applications of the Principle Leverage

IT seems that Archimedes, who discovered the law of the lever, thoroughly understood the principles of modern advertising copy writing. If he had enunciated his law in the now familiar text book form—"the moment of the load is equal to the moment of the force"—he would have created hardly a ripple of interest. So he thought up a way of putting more punch into its statement and put it thusly: "Give me a fulcrum point for a lever and I will move the earth."

This forceful enunciation of the simple law has lost none of its impressiveness even to-day, after more than two thousand years, and, enthused by the wonderful possibilities thus indicated, inventive minds are constantly at work in an endeavor to apply the great force of the lever to the solution of some of our every day problems—sometimes with rather startling results. A Montana inventor, for instance, has created a leverage system which he has applied to a well-known make of automobile engine, increasing the horsepower of that engine (we are assured) nearly 100 per cent. The crank throw is said to be different from the piston stroke. In an advertisement of the company promoting the invention, appearing in a Montana newspaper, a number of residents of the neighborhood vouch for the increase in horsepower. It would not be difficult to concede that a leverage system might increase the torque, and the thought occurs that possibly the men who attested the brake horsepower tests do not understand the difference between torque and horsepower or between force and power.

Archimedes' famous statement regarding the possibilities of the lever is quoted also by a Denver concern which has made what is claimed to be a new application of leverage in tractor construction. Instead of hitching the plow to the tractor frame, it hitches same to a crossbar fitted with rollers at its ends which travel on circular tracks secured to the driving wheels and concentric therewith. This is said to transfer the fulcrum point of the drivers from the axle to the

point of ground contact, and thus to prevent all slipping of the wheels. The fulcrum point of a rolling wheel is a rather novel conception. It is quite plain, however, that when a tractor exerts a drawbar pull there must be a reaction to this pull, and this occurs between the wheel rims (and their lugs) and the ground. If the load to which the tractor is hitched is excessive and there is sufficient engine power and a sufficiently large gear reduction, the drivers will slip, no matter how the load is hitched.

The lever will serve very well for multiplying forces, but in the same measure as the force is increased the speed of the motion is decreased and the power (or rate of doing work), therefore, remains the same. By a slightly more complicated mechanism we can even multiply horsepower, but in the same measure as the horsepower is multiplied the time of application is reduced. All attempts to use the principle of leverage for multiplying the power of engines must necessarily end against the stone wall of the law of energy conservation.

The S. A. E. and Research

THE announced intention of the Society of Automotive Engineers to enter actively the research field has been made the occasion of many letters addressed to AUTOMOTIVE INDUSTRIES and pertaining to proposed activities along this line. While some of these correspondents foresee some dangers and difficulties that must be guarded against if the new activity is to succeed, we have yet to hear anything but commendation for the basic undertaking.

It is quite generally agreed that it is necessary to the success of the project to make haste slowly, lest the plan be discredited by ill-considered action or mistakes in policy. Time in planning will not be lost, of course, if this time is used in establishing a sound foundation. One correspondent points out the need for laying out a complete program before conducting any actual research as a means of avoiding the possibility of becoming involved in a mass of details and losing sight of the most important items. It is obviously desirable to start first the items of greatest importance, later elaborating on details in logical sequence.

Another correspondent mentions the fact that few industrial organizations have the funds required for what may be termed fundamental research, but greatly need much fundamental data, now lacking, in order to start specific developments on a sound basis. Such data can, he says, be best developed through research in university and government laboratories, which will gladly undertake the work when it is once agreed what is required. The S. A. E., it appears, can and should be the directing and co-ordinating body, and serve as a clearing house for collection and dissemination of data from all available sources. When data in hand requires checking and when gaps in the available information need to be bridged, the S. A. E. should assign the problem to one or more laboratories, follow it through, and publish the resulting data in convenient reference form.

The belief is quite general that research involving fuel and its efficient utilization is of primary importance, and there are, of course, many angles to this problem which seem of pressing importance. Some consider that development must take place along lines that will make the automotive engine independent of specialized and high-priced fuel. Study of fuel injection is suggested. Means for controlling temperature inside the cylinder, study of the laws of heat transfer, behavior of various fuels, study of means for producing cheaper alcohol, and many related matters are mentioned as being of importance. One engineer suggests the need for dividing fuel research activities into two parts: those which relate to future designs and those applicable to equipment now in use or in process of manufacture, since much of this equipment will continue in operation for many years to come. It is evident that study of means for improving fuel economy, especially at part load, is needed and should constitute an item of first importance.

The fuel problem so far overshadows other matters of importance that little space is devoted in the letters received to the need for consideration of what may be termed mechanical research, but some draw attention to the need for improving mechanical efficiency, especially in the engine, and for lowering resistance to motion of the car (drawbar pull), while others cite the need for study of factors tending to increase the life of parts and lower cost of operation. In this connection weight reduction and elimination of nonessential equipment are mentioned.

Several correspondents point out the importance of keeping clear of patent considerations in all activities undertaken by those who have the research program in hand. Similar caution in this regard has been observed in connection with S. A. E. standardization work, but it will, it seems, require even greater attention in reference to research work.

There seems, on the whole, to be little question of the hearty support and ultimate success of the proposed activity, if the foundation is well laid and the work prosecuted in a thoroughgoing and persistent manner.

Complicated Practice; Simple Principles

SOME men who call themselves "practical" are inclined to scoff at those whom they choose to call "theorists." There are so many "practical" men and so many difficulties in industry that it sometimes leads one to wonder whether or not the high proportion of both is not more than a coincidence.

All sound practice is based on theory, and clear, logical thinking in an abstract way is necessary to the development of intelligent practice. Prof. Einstein has said a lot of things that only a few can understand, but he recently made a statement that has a clear meaning and a direct application to the problems of industry. He said:

"Complicated events flow from a few simple principles, and the more we know the fewer and simpler are the principles." But simple principles must not be confused with superficial catch-words or formulas as is sometimes the case.

Bad Weather Leads in Sales Check

Price Uncertainty Is Another Factor

Prompt Action Needed for Stabilization—Wall Street Hysterical Again

By James C. Dalton

NEW YORK, May 16—Temperamental Wall Street is worried again about the automotive industry and is selling motor stocks short. This is its reaction to price cuts, a slight decline in retail sales for April and lower dividend rates. This attitude in the "street" is nothing new and in it there is no new significance.

There is real significance, however, in the remarkable "come-back" of the industry at a time when the entire country is crying depression. Automobiles were one of the first commodities to bear the full brunt of the buyers' strike and they were one of the first to feel the pulse of renewed demand. This recovery in the middle of a prolonged period of deflation proves that the industry is on a stable foundation. Its future is vastly more assured than that of the railroads whose securities once were the chief source of revenue for widows and orphans.

Business in the United States never has been called upon to meet problems exactly like those which it has been compelled to face for the last year, but there never has been a period of depression from which the country has not emerged on an even keel. There have been ups and downs for every line of industry and there will be now.

It was not to be expected that when sales of automobiles began again after the serious slump of last fall and winter they would forge ahead steadily, month by month, with each thirty-day period better than the one preceding. That condition never has prevailed in normal times and it never will. Certainly it could not be expected under the abnormal conditions which prevail now.

Business Largely Seasonal

The automobile business, in its very nature, has been largely seasonal. This applies to commercial vehicles as much as to passenger cars. Until good roads become universal and until snow removal becomes a science this always will be true.

Passenger car sales in all except southern states always increase to a peak in early summer, and there always is a drop in the sales curve about July 1 when the first summer demand has been satisfied. After that sales forge ahead in a satisfying way and business is good in late summer and early autumn, reaching its ebb about the first of the year when winter has taken its first firm grip. From this ebb the rise begins gradually and spring sees a sharp upshoot in the curve.

The spring demand began this year abnormally early. The winter was remarkably open and the weather for the first quarter was more spring-like than it has been since then. It was only natural, therefore, that sales of cars started from six to eight weeks sooner than they would under the usual weather conditions. Such being the case, it would be remarkable if they did not fall off a little earlier.

Sales at retail were somewhat smaller in April than they were in March. That was due in large measure to the cold, raw weather which prevailed in nearly all sections of the country. It might be pointed out, however, that sales of winter overcoats, which usually start in late October, did not get under way last year until nearly Christmas. The topsy-turvy weather was the reason for that, just as it has been the chief reason for whatever slump there has been in automobile sales for the last month.

Proceeding With Caution

After its sad lesson with huge inventories purchased at high prices, the automotive industry is proceeding with the utmost caution. It is buying on a hand-to-mouth basis. This applies to all branches of the industry. Orders are placed only for goods which are actually needed and prompt deliveries are demanded. Sometimes, the parts makers contend, the demands in this direction are unreasonable. They are again beset by stock chasers.

AUTOMOBILE SALES INDEX TO BUSINESS

NEW YORK, May 14—The following statement in reference to automobile conditions as contained in the monthly review of business conditions issued by the Northwestern National Bank, the largest in the Northwest, indicates the change in sentiment toward the automotive industry on the part of bankers:

"Automobile sales now are looked upon by many as one important index to business conditions. Although the industry is not so basic in character as some that by the rise or fall of their activity affect conditions generally, it has become so great in recent years that its availability for general guidance is more generally recognized."

Sales Slump Hits Lines Not Reduced

Buying Gains in Cars Repriced Offset by Check in Other Makes

NEW YORK, May 16—With the exception of Studebaker, practically all lines of cars handled in New York have been unfavorably affected by the price reductions on Marmon and Jordan more than two weeks ago, and on Oakland and Chevrolet announced last week. The four cars which reduced have been selling strong, Marmon particularly having made a big gain this week over sales during the first week of the lower priced period.. Oakland and Chevrolet sales started with a rush, naturally most noticeable in the latter line, Monday morning following the appearance of the reduced price announcement in the Saturday and Sunday newspapers.

Marmon sales have been so heavy that the accumulated stock of cars has been cleaned out except for three enclosed models. The distributor is even forced to do without the four passenger and seven passenger demonstrators. Orders for factory shipments during May have been largely increased. Marmon distribution outside the city is handled by five dealers, all of whom this week had the largest single week's sales since they took the Marmon representations.

Oakland sales have been multiplied several times in both the New York and wholesale territories. Chevrolet sales are strong throughout the territory and orders are pouring into the factory at Tarrytown. In the New York salesroom the sales force has been practically swamped with demands for attention from salesroom shoppers.

Studebaker Six Weeks Ahead

Studebaker sales, which have increased steadily since the first of the year, have now reached a point where orders are being taken subject to six and eight weeks' delay in delivery. Recent price reductions in other lines apparently have not affected Studebaker in this territory up to date.

Generally speaking, however, passenger car sales have suffered acutely from recent price reduction announcements. In some lines sales have been virtually halted by an attitude on the part of the public which indicates that lower prices are confidently expected. Several of the lines which have been selling strongly for the past month or two have been affected by competitive reductions, sales on some of these popular classes drop-

Bankers Name New Goodyear Head

E. G. Wilmer Succeeds to Seiberling Place

Stadelman and Litchfield Continue as Vice-Presidents—Directors Reorganize

NEW YORK, May 16—Edward G. Wilmer of Milwaukee, vice-president of the Steel & Tube Co. of America, will succeed F. A. Seiberling as president of the Goodyear Tire & Rubber Co. under the reorganization plan which became effective when bankers formally took control of the corporation. He is a close friend of Clarence Dillon of the banking house of Dillon, Read & Co. of New York which headed the syndicate of bankers which has successfully put through the refinancing plan under which $85,000,000 in new securities will be offered. Wilmer, who is only 38 years old, has been identified with the mining, steel and chemical industries. He will move from Milwaukee to Akron and it is said he will have a free hand in the management of Goodyear.

The only Goodyear officers prominent under the Seiberling régime who will remain are George M. Stadelman and P. W. Litchfield, both of whom retain their positions as vice-presidents. Vice-president C. W. Seiberling retires with his brother.

The ousting of F. A. Seiberling from the head of the great tire company which he built up is one of the most dramatic and tragic incidents which has followed the period of depression into which the country was plunged nearly a year ago. The financial difficulties which resulted in his downfall were the result of the enormous inventory accumulated at high prices and the very large number of contracts made for future deliveries of crude rubber and long staple cotton.

Organized With $12,000 Capital

Seiberling, who is now recognized as one of the leading figures in the rubber industry in the world, began 23 years ago with $12,000 borrowed capital with which he founded the Goodyear company. From this small beginning the company grew until it became the second largest rubber company in the world with more than 50,000 employees, 100 acres of floor space in its Akron factories, a rubber plantation in Sumatra, tire factories in Canada and California, a 56-acre cotton plantation in Arizona and fabric plants at Goodyear, Conn., and Los Angeles. The company attained a peak production of more than 50,000 automobile, motor truck and motorcycle tires a day. It gave the motoring world

Seiberling Says He Will Take One Month's Rest and Then He'll Go to Work—at Something

AKRON, May 16—"I am going to clear up my personal affairs next week and then go away for a month's rest. When I come back I shall go to work—at something."

This statement was made to-day by Frank A. Seiberling, who retires as president and director of the Goodyear Tire & Rubber Co., which he founded.

"My brother, C. W. Seiberling, and myself, sever all our relations with Goodyear and control of the business passes into the hands of the bankers as provided in the reorganization plan," he said. "Both of us continue our interest as the company's largest stockholders. For 22 years we have labored together and what has been achieved the world knows. The nation-wide slump in business last fall brought our business to the verge of disaster. Since that hour I have had but one purpose—to save this business from a receivership and this community from the results of such a calamity. That was accomplished yesterday and the new management inherits a business soundly financed.

"My successor, E. G. Wilmer, of Milwaukee, is a young man of fine legal training and broad experience in operating business, and with the return of the world to normal business there is no reason why Goodyear cannot move forward to a higher plane than it has yet achieved. The bankers in control made me an exceedingly generous offer to continue with the business, which, after careful consideration, I felt justified in declining.

"What I am going to do next I do not know. Since I left school 44 years ago I have labored hard, enjoying my work all the way along, through all its difficulties, up to within the period of the last six months. In truth, I have been tired during that period. The burden is now all off my shoulders, except for a few days I have had no vacation in over two years. I am going away for a month's rest and when I come back I shall go to work—at something."

Goodyear Files Show Business Struggles Fought by Seiberling to Win Success

AKRON, May 16—It is interesting to go back through the files of the Goodyear history from the time in 1898 when F. A. Seiberling started the company with a capital of $12,500, of which only $3,500 was cash—and that borrowed—and to follow the progress of the concern through years and months of troublesome times, up until the present when Goodyear at its peak a few months back had over 50,000 employees throughout the world.

First Directors Unfriendly

The Goodyear company, housed in ramshackle buildings in East Akron, where now stands the Goodyear plant valued at nearly $60,000,000, was forced to expand. But expansion meant re-financing and Seiberling presented to his directors plans for the securing of $150,000 of additional capital. His directors, many of them unfriendly to his personal interests, guaranteed the re-financing upon condition that the Seiberling brothers pledge the majority of their stock, and endorse the notes as evidence of good faith. Willing to make the personal sacrifice for the sake of their concern, the brothers announced the plan as acceptable, until they discovered hidden in the phraseology of the terms, clauses which would have transferred control from the two, robbed them of authority, and practically ousted them from the company.

The directors brought presusre to bear and issued the ultimatum that unless the two brothers surrendered unconditionally, all arteries of financial aid would be completely shut off.

One director who had advanced $10,000 to meet the company's payroll, demanded instant reimbursement. Goodyear records show that President Seiberling unflinchingly, although he did not know where the money would come from, calmly replied, "I will get your money for you by 5 o'clock."

Appearing before directors of an Akron bank which was none too friendly to him, and yet the only financial institution he could call upon for aid, Seiberling's outspoken frankness was attended by success. By 5 o'clock the turbulent director's $10,000 was in his hands, his stock was purchased by interests more friendly to the Seiberling brothers, ample credit was secured to endorse the company's paper, and the crisis was averted.

Averted Crisis in 1903

Again in the panic of 1903, Goodyear lived through another serious financial crisis. Approximately $800,000 of the company's paper, most of it in notes, was

(*Continued on page* 1081)

Senate Clears Way to Aircraft Dumping

Penrose Takes Position There Is No Air Industry Here Requiring Protection

WASHINGTON, May 16—Efforts of Senator New of Indiana to protect American aircraft manufacturers from foreign competition by a specific amendment to the anti-dumping bill failed Wednesday because Republican leaders insisted that the proposition was utterly indefensible. The New amendment was designed to block the sale here of surplus airplanes by the Aircraft Disposal Co., organized in Great Britain.

In opposing the proposition on the floor of the Senate, Senator Penrose of Pennsylvania, chairman of the Senate Finance Committee, insisted that it was an attempt "to tax the Government of the United States several hundred million dollars for fostering an alleged American industry which is non-existent." Senator New challenged the assertion of the Pennsylvania senator with the statement that 20 concerns are now making aircraft or aircraft parts in this country with great opportunities for expansion because of the commercial demand for airplanes.

Senator New pointed out that 100 airplanes were imported to this country after the armistice for sale here, but were not put on the market because of the effective campaign by American manufacturers. These aircraft producers appealed to the United States Court, and the court held that the British planes were based upon an American patent and did infringe upon that patent. He insisted that these planes are now in bonded warehouses at eastern ports ready to be put on the market here at any figure that their American owners can get for them.

The Senate was advised by Senator New that 30 concerns were making airplanes and about 20 others making aeronautical motors at the time of the armistice, representing a capital investment of $100,000,000 and employing 200,000 operatives. He declared that there was now perhaps a total of 2500 operatives within the industry hoping to remain in the field if not pushed out by foreign competitors.

He declared that manufacturers will not be warranted nor able to attempt to revive the domestic market until they receive ample protection.

See Plane Dumping Move in Handley Page Visit

NEW YORK, May 16—The Aero Club of America and its affiliated organizations in the principal cities of the United States have called the attention of President Harding and the Secretaries of War and Navy to the arrival in this country of Frederick Handley Page, head of the British syndicate organized to dispose of surplus aircraft. It is his purpose to sell a large part of this equipment in the United States.

Successful litigation by Amerian owners of patents used in British machines has interfered thus far with the sales. It is expected, however, a new effort to get business will be made coincident with the defeat of an amendment to the anti-dumping bill offered by Senator New. This amendment would have provided that the appraisal value of aircraft imported into this country should be based on the cost of production rather than on the 1 per cent of the original cost which the British interests paid for the war material. This amendment was defeated by Senator Penrose who asserted there was no American aircraft industry worth mentioning and that the United States should go to England for its airplanes if it could get them more cheaply there.

Slough Trading to Sell Trucks in South America

LONDON, May 2 (By Mail)—Plans of the Slough Trading Co., Ltd., for exporting to the United States a large number of the American made motor vehicles bought from the British Government have suffered a serious setback because of the opposition from American truck makers. Many of the trucks which had been stored at the Slough depot were requisitioned by the Government in connection with the threat of a strike by the "Triple Alliance," but as the strike did not take place they were not used. All the vehicles have been reconditioned and the company expects to ship a considerable number to South America, especially the Argentine.

The company has an enormous quantity of spare parts and the prices can be judged from the fact that new Packard cylinder blocks were quoted at $125. Lucas lighting generators, the normal price of which is $100, are marked at $20 in lots of 10.

The general use of the straight side tire makes them look like the British standard, but the fact is more of a tribute to successful American competition than to any recognition of the superiority of this type of tire. There has been a big drop in tire prices but there is little trade because so few vehicles are being built.

Strike Ties Up Daimler

The Daimler works at Coventry are almost at a standstill because of a wage dispute with the 1700 workers. The company's employees had been working on a premium bonus system and not on direct rates for piece work until it was proposed recently to introduce a new line of work with the object of increasing sales and providing more employment. This is believed to refer to a lighter and cheaper Daimler car.

The union objected to this plan, claiming that the standard time rates were affected by the proposed revision. It was contended the proposal would re-

(*Continued on page* 1085)

Experts to Teach Parts Units Service

Factories Launch Campaign to Improve Conditions — Will Tour Principal Cities

DETROIT, May 16 — Demonstration lectures to service managers, mechanics and others concerned in the repair and servicing of automobiles and trucks will be given in various cities, beginning tomorrow with a lecture at the Cadillac service station here under the auspices of the Detroit Automobile Dealers' Association. The lectures have been arranged through the efforts of Harry G. Moock, manager of the N. A. D. A., and officials of Continental Motors Corp., Timken-Detroit Axle Co., and Borg & Beck. An expert from each of these companies will lecture on proper servicing of those parts and will give demonstrations in repair work.

Experts employed by other manufacturers of standard units will be added as rapidly as is possible and it is hoped to extend the work to cover every large distributing center in the country. In each case the local dealers' association will have charge of arrangements for the lectures, bearing the necessary expense and attending to the work of bringing out a full attendance of those sought to be reached.

Two nights will be devoted to each city and the itinerary of the lectures following the Detroit meeting will be Cincinnati, May 19 and 20; Indianapolis, May 23-24; St. Louis, May 31-June 1; Kansas City, June 3-4; Omaha, June 6-7; Chicago, June 9-10-11, and Milwaukee, June 13-14. A change in the schedule to include Minneapolis is probable. There will be no sales or advertising propaganda used in connection with lectures.

Draymen's Association Asks Service Stations

LOS ANGELES, May 17—The Southern California division of the Draymen's Association has adopted resolutions requesting manufacturers of complete unit parts to establish parts stations at which genuine parts can be purchased at fair and uniform prices for the units now being manufactured as well as those which are considered obsolete. This method, the resolution asserts, is the only practical way in which motor truck users can get the service to which they are entitled.

The assertion is made that past experience demonstrates that distributors and agents either cannot or will not carry a complete stock of parts. Another difficulty, it is stated is that manufacturers are constantly changing their representatives as well as their models and that as a consequence members of the association constantly are finding themselves with broken down equipment because no one carries the parts needed.

Du Pont Finances G. M. C. Purchase

Will Sell $35,000,000 in Gold Bonds to Close Transaction with Durant

NEW YORK, May 16—The stock transaction in which E. I. duPont de Nemours & Co. purchased control of the General Motors Corp. from William C. Durant, formerly its president, in the liquidating market of November, 1920, is to be financed permanently by an issue of $35,000,000 7½ per cent 10 year gold bonds.

J. P. Morgan & Co. have purchased the issue from E. I. duPont Nemours & Co. and will offer it today through a nation-wide syndicate at 100 and interest to yield 7½ per cent. The bonds, dated May 1, 1921, are redeemable at the option of the company, in whole or in part, on 60 days' notice, at 110 and interest, at any time prior to May 1, 1922. Thereafter the redemption price decreases 1 per cent yearly.

The formal announcement of the banking house said:

"The proceeds of the bonds will be used partly to supply funds for permanently financing the cost of the common stock of the General Motors Corp. purchased last year and for other corporate purposes."

Approximately $25,000,000 will be required to finance the stock transaction permanently. The additional $10,000,000 is for corporate purposes.

This General Motors stock now held by the duPont Securities Co. amounts to approximately 4,000,000 shares in all. A total of 2,504,273 shares was acquired by purchase from William C. Durant in November for $23,790,600 in cash and 40,000 shares of the duPont Securities Co. Subsequently, the duPont Securities Co. gave Durant 230,000 shares of General Motors common stock for his 40,000 shares of duPont Securities Co.

To Wind Up Holding Company

It was said yesterday by the bankers that the affairs of the DuPont Securities Co., formed temporarily to hold control of General Motors, would be wound up. Its assets will be taken over by the DuPont American Industries, Inc., whose capital stock is owned entirely by E. I. duPont de Nemours & Co. Into this concern's treasury will go $7,000,000 of General Motors stock; $20,0000,000 of the preferred stock of the duPont Securities Co. and all of its common stock, under a trustee arrangement. The DuPont American Industries, Inc., in turn, will issue $25,000,000 of its bonds to the parent powder company.

It was made plain by the bankers that the General Motors Corp. was not identified with the current financing in any way, and that its mention came only because a sale of this particular stock needed financing. It was made plain by the bankers, too, that the control of General Motors was vested in E. I. duPont de Nemours & Co. and that the stock would not again come on the market. The Street has heard rumors that the purchase of the stock at forced sale was a temporary expedient and that some of it might be resold in the open market to reimburse the purchasers. These reports are set at rest by announcement of the permanent financing.

G.M.C. Stockholders Increase to 58,000

NEW YORK, May 13—Stockholders of the General Motors Corp. now number more than 58,000. This is an increase of approximately 30,000 in the number of common shareholders, which is regarded as significant in view of business conditions in general and the automotive industry in particular during the past eight months. This number does not include the holdings of individuals standing in the names of brokers and bankers.

The tabulation shows that investors own 18,860,881 shares of General Motors common, an increase of 4,694,257 in a year. The number of common stockholders at the beginning of May, 1920, was 7193, and it is now 37,991. The increase in the number of holders of preferred and debenture stock has been much less marked, growing from 18,943 to 20,833 in the year. An indication of the extent to which the floating supply of General Motors common is being absorbed by investors is seen in the fact that among stockholders owning from one share up to 200 shares there has been an increase of 130,000 shares in the last three months.

G. M. C. TO RENT OFFICE SPACE

DETROIT, May 14—The executive committee of General Motors Corp., has approved the rental of the second and third floors in the east half of the building, to outside firms or corporations. This gives approxmiately 50,000 sq. ft. of floor space which the announcement says can be made ready for occupancy by July 1. For a time it was the intention to devote the entire building to General Motors interests and many applicants for office space were turned down. Since the change in management however several changes in the policies of the company have been announced and the proposal to rent office space is the latest. Persons who had applied for space are being notified that they can be accommodated.

CHEVROLET PRODUCTION RISES

FLINT, MICH., May 14—The local plant of the Chevrolet Motor Co. began increasing its force at a rate which is expected to add 1500 men within the next two weeks with all departments operating on full time. General Manager C. F. Barth said the increased operations were due to greatly increased sales demand following announcement of the recent price reduction.

Lay High Insurance to Moral Hazards

N. A. C. C. Committee Would Eliminate Loose Methods in Accepting Risks

NEW YORK, May 17—The insurance committee of the National Automobile Chamber of Commerce, of which W. E. Metzger is chairman, has sent to its members a bulletin declaring that in its opinion the present high rates are due to the loose methods in accepting risks and that insurance companies "should scrutinize the moral hazard." The bulletin says:

"The cost of insurance to car and truck users has mounted steadily. In the belief that this is very largely due to loose methods on the part of insurance companies in accepting risks regardless of moral hazard we have taken the position, in public statements on this question, that underwriters should scrutinize the moral hazard, and that in the meantime mutual insurance companies which cover the public at much less cost are to be encouraged.

"Accidents are not prevented by liability insurance, which, on the other hand, tends to promote recklessness. The amount of fire and theft coverage allowed on cars and trucks, particularly after the first year of their use, frequently exceeds actual value; this minimizes care and encourages their being destroyed and reported as stolen by unscrupulous owners. These costs are spread over the policies of the great majority of responsible owners.

"The new plan of grouping cars according to construction features determines comparative rates but can have little effect on total fire losses, since a very small proportion occur from integral causes. It does not go to the main point of reducing total costs to the public, which is of direct interest to manufacturers.

"According to figures given out by 131 insurance companies, the fire and theft premiums received by them in 1920 amounted to $74,472,250. The losses paid amounted to $42,935,748.

While manufacturers are carefully studying the schedule of hazards of the underwriters' laboratories, in which are listed features of construction considered by underwriters to have a bearing on risk, we are presenting the point of view that while this may be helpful, it offers little hope of any great reduction in the average insurance premium per car."

Makers Consider Company

NEW YORK, May 16—The *Eastern Underwriter*, an influential insurance newspaper, says: "It is reported that automobile manufacturers are discussing the advisability of forming an insurance company or companies because of the high automobile rates, which are re-acting in car production. Some people are not buying cars because they cannot afford the insurance."

Weather and Prices Lead to Sales Check

Nobody Caught Napping Through Business Slackening—Price Situation Expected at This Time

(*Continued from page* 1076)

Production schedules for automobile factories are based largely on the business done the previous month. Under the conditions which prevail at present, if the sales for April fell below the mark expected, the schedule for May will be cut. Factories now are making only enough cars to meet actual demands.

The fundamental soundness of the industry has not been affected, however. The industry daily finds itself more solid than it has been for months and much of this solidity is due to the fact that nearly every condition that arose within the last year had been foreseen and the leaders of the industry are still far in advance of the present situation.

A falling off in sales at this time has been expected. Nobody has been caught napping. In fact, AUTOMOTIVE INDUSTRIES, which has chronicled in advance most of the moves and trends of the past year, has had in its office for some time a report from the national sales field, indicating that the encouraging upward swing of sales in the spring would not continue unbroken.

It has been known for months that a price situation was inevitable about this time. When prices broke last fall the industry adopted a stabilizing policy of making immediately any changes that were to be made. Numerous prices were adjusted and those that were not changed were guaranteed until about this time. That stabilization helped materially during the winter months. Now the next step in the readjustment has been reached and what is needed is stabilization as quickly as possible. Those who are going to adjust should do their adjusting early and help set the stage for a continuation of selling. Until the adjustment is made sales will be more difficult, for the public will not buy on a continuously falling market. Those who are not going to cut should say so and the rest should change their prices and have it over with.

Buyers Waiting Stability

Reports from the entire country say that buyers are ready to hold off until prices seem stable and there is a feeling that there will be good business in the last half of the summer and during the fall if the stabilization can be effected quickly. Sales of the entire industry will be affected if the companies adjust, one by one, for the rest of the summer.

Price must be taken into consideration in the present situation. Cars which show value for the money are having good sales and have had. Some cars may be comparatively over-priced and it is not a perhaps remote possibility that the 1921-22-23 profits of some companies for the term of years might be greater if adjustment to conditions were placed first and full profits second for the remainder of the present year. A healthful readjustment to a basis that would require little change for months to come would be beneficial. Keen students believe the peak of sales in the industry has not been reached and that the next few years will be the greatest ever seen in motor vehicle sales.

Stabilization of prices on all products is also essential. The agricultural areas are affected by the relation between farm product prices and the prices of other commodities and in many general items, such as are sold in department stores, even the proprietors of the stores are having trouble forcing their own prices down. Incidents have been found of department managers who mark goods even higher than the store owners desire in order to make the particular department show up well in the total store profits, in which the department manager, of course, participates. It is not possible to know how extensive such cases are, but they are regarded as an evidence of the lingering desire of the man who tasted war profits not to loosen his hold on the joys of the hey-day period. A recent conference in Washington of the National Conference of Business Paper Editors developed considerable information of this character.

Some Banks Antagonistic

In some sections, particularly the southwest, the old score between the automobile industries and the banks remains to be wiped out. It does exist. A bad impression still prevails and much good is expected to come from an address which Governor W. P. G. Harding of the Federal Reserve Board is to make in Kansas City May 21.

Reports gathered from the national field show instances of dealers who are getting more business than might be expected because of more intensive sales work. One dealer is holding his volume to normal but is using three times the usual number of salesmen to do it. Another dealer is taking cars in the rough and producing what is practically special models in color, and he makes the point that no matter what happens the dealer who works will still get some business.

Most interesting in considering the future is the statement by one student of affairs that when the world gets back to working and buying we shall have a new crop of buyers.

Reparation Terms Important

A potent factor in the return of better business is the recent acceptance by Germany of the reparations terms. It is the most important move toward world prosperity since Nov. 11, 1918, and the handling of the subject in the daily press has not been at all in accordance with what the acceptance means to the workers in American factories. England, as she has done for hundreds of years, undoubtedly will extricate herself from her present trouble with no disastrous consequences. Russia will always be a sore spot until her people return to productivity.

Dallas Car Registry Tallies with 1920

Figures for April Both Years Is 573—Other Texas Cities Report Activity

DALLAS, TEX., May 16—That the automobile business has about returned to normal in Dallas is clearly indicated by the number of new cars registered, according to dealers. During the month of April, 1920, a total of 573 new automobiles were sold and registered in Dallas County, and by a coincidence, 573 cars were sold and registered in Dallas County in April, 1921. The majority of the cars sold are priced from $1,200 to $2,500.

Dealers in Fort Worth and Wichita Falls declare business during April better than for the same period last year. From other north Texas cities and towns like Greenville, Sherman, Paris, Denison, Corsicana, Gainesville, Denton and Terrell, dealers report business improving. Accessory and repair men in these places make similar reports. The truck business appeared to suffer a slump during the past month. This is believed to be due to the heavy truck tax law which becomes effective in July.

Sales Slump Hits Lines Not Reduced

(*Continued from page* 1076)

ping off from 25 to 50 per cent during the past week.

Salesmen report a much wider use than formerly of the "prices have got to come down" argument by prospects who seem to be sold on the cars offered them but absolutely refuse to sign contracts. Several dealers in lines guaranteed to mid-summer have found the guarantee of little avail in the face of present conditions, prospects in a good many cases declaring that they will "wait a couple of months and see what happens." Distributors of cars which have been subject to recent price reductions are "making hay while the sun shines."

Chicago Finds Tendency to Wait Lower Prices

CHICAGO, May 17—While sales are being made in this territory there is evidence of a holding back on the part of many prospects due to the recent cut in the prices of some automobiles and the resultant questions that they raise in their own minds of how extensive this price reduction will be—if it will not, within the course of a few weeks, reach most of the lines. The same feeling of hesitancy that appeared last September when the price reductions started is again noticeable.

This feeling is true particularly among those prospects who would buy cars in the classes where a guarantee of price has been made.

Goodyear Files Show Route to Success

(*Continued from page* 1077)

in the hands of bankers scattered throughout the country. To cap the climax the company's chief endorser was himself plunged into financial difficulties and made plans to leave the country. President Seiberling and his brother, securing a list of notes and waivers of endorsement, started in opposite directions to seek extension of all loans.

While returning from New York, Seiberling evolved the strategic plan of selling the business, or at least of securing a contract for sale, for to have negotiated a sale within the limited time necessary in order to meet the notes was impossible, as one-third of the $800,000 was due within three weeks. He returned to Akron with a contract calling for the sale of the Goodyear business to a rival concern upon terms which would pay stockholders a substantial amount on their holdings, as his weapons with which to stave off impending ruin.

To add to his tribulations came the sudden death of his father. But undaunted he went before the directors with his contract. Pinning their faith in his ability, although deploring the thought of selling the business, the directors instantly approved any step he might deem necessary to meet the exigencies of the occasion. But the directors did not know that selling the business was the least of Seiberling's thoughts until he told them he would use it merely as a defensive weapon to stay the hand of impatient creditors.

"With this document," he said before that memorable meeting seventeen years ago, "I shall gain added confidence, secure extension of all loans, and even get those same creditors to loan us more money."

The two brothers then started out. There were 155 creditors scattered throughout the country, to be seen personally. And after weeks of traveling, the brothers returned, with faces wreathed in smiles, for the creditors, impressed by their frankness and past record of achievement, gave them the added confidence sought and provided the additional financing required.

Grew to 80 Unit Plant

From that time Goodyear grew rapidly. The Akron plant of eighty buildings comprising one hundred acres of floor space, had over 31,000 employees and a capacity of 35,000 tires daily. Goodyear had 74 branches scattered throughout the world.

Sales were $69,000 in 1910, jumped to $169,000,000 in 1919, and exceeded $200,000,000 last year. Every year since 1903, the officials, with substantial uniformity, were able to state in annual reports that "the past year's business has been the largest and most successful in volume and profits of any year in the history of the company."

For the first six months of the fiscal year beginning Nov. 1, 1919, Goodyear business was running 59 per cent greater than for the same period of the year before, with the demand for product far beyond the company's ability to supply. This entailed financial requirements beyond normal and the company offered to stockholders two shares of preferred and one of common stock at par, selling thereby $27,794,700.

Then came financial deflation, the tightening up of credit and slowing down of the automotive industry, with resultant lull in tire sales. Retrenchment became necessary and additional financing became imperative, this latter being accomplished by providing in new money and extension of bank paper $28,800,000 maturing February 15, 1921. The process of readjustment and deflation affecting all lines of industry proved especially severe to the rubber industry, raw materials, including both rubber and fabric having in a few months dropped in value over 50 per cent. This meant a loss to the company on contractual obligations of $19,000,000, in addition to the deficit of $15,647,653.56.

November was the low ebb of Goodyear operations. Business then began to pick up and sales increased encouragingly.

The company's annual statement listed the value of the Akron plant at $57,913,143.46 and the Sumatra rubber plantation at $5,003,257. Investments in and accounts due from domestic subsidiary companies wholly owned were $13,352,158 with $21,179,529 listed as due from subsidiaries not wholly owned, and $4,393,217 due from foreign selling subsidiary corporations.

The annual statement also showed that an account of $3,568,445 due the company from President Seiberling had been closed by Seiberling depositing as security 75,000 shares of $7,500,000 par value in the Akron, Canton and Youngstown Railway Co., and 250 shares in the East Akron Land Co., the Goodyear Co. thereby taking over one-half ownership in the railway and taking over the Goodyear athletic field of thirty acres, owned by the East Akron Land Co.

Dunham Heads Division on Axles and Wheels

NEW YORK, May 17—The Council of the Society of Automotive Engineers has appointed an Axle and Wheel Division to consider the question of standardization. G. W. Dunham of the Savage Arms Corp. is chairman of the division, and the other members are: C. C. Carlton, vice-chairman, Motor Wheel Corp.; T. V. Buckwalter, Timken Roller Bearing Co.; R. J. Burrows, Clark Equipment Co.; J. Coapman, Russel Motor Axle Co.; C. S. Dahlquist, Standard Parts Co., Eaton Axle Div.; F. W. Gurney, Gurney Ball Bearing Co.; Geo. L. Lavery, West Steel Casting Co.; A. M. Laycock, Sheldon Axle & Spring Co.; C. T. Myers, consulting engineer; A. L. Putnam, Detroit Pressed Steel Co.; J. G. Swain, Firestone Steel Products Co.; G. J. Thomas, Duplex Truck Co.; H. Vanderbeek, Timken Detroit Axle Co.

E. G. Wilmer Succeeds to Seiberling Place

(*Continued from page* 1077)

the pneumatic tire for commercial vehicles.

The interests which now control the company have elected the following directors: J. P. Cotton of Franklni, McAdoo & Cotton, New York; P. W. Litchfield, Akron, Grayson, M. P. Murphy, New York; J. R. Nutt, president of the Union Trust Co. of Cleveland; Robert C. Schaffner of A. B. Becker & Co., Chicago; A. A. Schlesinger, president of the Steel & Tube Co. of America, Milwaukee; G. M. Stadelman, Akron; Ralph Van Vechten, vice-president of the Continental & Commercial Bank of Chicago, and Edward G. Wilmer of Milwaukee.

The directors elected H. H. Springford as treasurer and Charles A. Stillman as secretary.

The reorganization of the board was the next to the last step in the rehabilitation of the financial affairs of the company, which has been attempted by the bankers. The first was in the offering of an issue of $30,000,000 of 8 per cent bonds. This last, to be taken within a few weeks, will be the offering of an issue of $27,500,000 of 10-year debentures, most of which, it is expected, will be subscribed by present stockholders.

Bankers for the company said that the raw materials now on hand had been written down to current market prices, that the factory at Akron now was turning out 19,000 tires per day, and that the outlook for the corporation under the new management was very promising.

Seiberling was in New York but did not attend the meeting. Officials of the corporation said that any comment about the removal of the former president from the board and from his position would have to come from him.

New Incorporation Filed

COLUMBUS, May 16—The reorganized Goodyear Tire & Rubber Co. of Akron has filed articles of incorporation with the Ohio secretary of state.

The articles provide for $140,010,000 of preferred capital stock and 1,500,000 shares of non-par common stock. In all, there are 2,910,000 shares of both classes of stock. The fee paid to the state was $290,010, the largest ever received by Ohio from a corporation for this purpose.

The reorganization scheme also provides for $30,000,000 8 per cent, 20-year first mortgage bonds, and $30,000,000 8 per cent 10-year debentures. The preferred stock is divided into three classes —$40,000,000 8 per cent prior preferred; $100,000,000 7 per cent ordinary preferred, and $10,000 6 per cent management preferred.

Mathews Cuts Light Price

SANDUSKY, OHIO, May 16—Mathews Engineering Co. has reduced the price of its farm lighting plant $150, the new price to be effective at once.

Austin Gets Funds from Private Source

Will Put Business on Satisfactory Basis If Creditors Approve—To Reduce Plant

By Cable to AUTOMOTIVE INDUSTRIES

LONDON, May 16—The Austin Motor Co. has arranged a private loan, subject to approval of its creditors, to put the business on a satisfactory basis. As a consequence the stock of the company is expected to react favorably. There is every likelihood of the proposal being accepted.

Argument in the High court for the compulsory winding up of the company's affairs has been postponed until May 31. Creditors whose claims are considerably in excess of $1,000,000 opposed the petition and asked for an adjournment.

Production at the Austin plant has not been suspended and there is no probability that it will be. It is likely, however, that the size of the plant will be reduced to something like the possibilities of the business.

Sir Arthur Whinney has been appointed receiver of the Austin company. During the war he acted as advisory to the Admiralty on costs of production and later as assistant accountant general to the navy. The receivership will be continued as long as necessary to reorganize the company's finances.

There is no disposition on the part of the industry in Great Britain to condole with Sir Herbert Austin on the state of affairs of his company. To the contrary he is being congratulated on the fact that financial control has passed temporarily into other hands. He is an experienced engineer and it is the firm belief that his company eventually will be placed on a solid basis.

At a private meeting of creditors Friday, Whinney reviewed the situation. He said the company had come to the end of its resources, that it was being sued, that it had no money to carry on and that the sheriff was in possession because of claims aggregating $200,000 filed by 26 creditors.

1920 Profits Over Million

The turn-over in 1919 was $12,500,000 and the profit was $1,290,000. The profits in 1920 were more than $1,000,000. The falling off in business in recent months was accounted for by the slump in trade. The present position of the company, Whinney said, was good as regards the reputation of its cars and the demand is greater than can be met under existing conditions. The output for the week ending May 14 was 77 cars. The value of the output for the first five months of this year was $3,935,000.

After considerable discussion by the representatives of creditors and on motion of the representative of the Dunlop Rubber Co., acting for creditors whose claims aggregate $2,000,000, the meeting was adjourned and a committee of six was appointed to confer further with Whinney.

The principal creditors disclosed were Van Dervells, for starting and lighting sets, $442,500; Fellows Magneto Co., $150,000; North British Lumber Co., $235,000; Dunlop Rubber Co., for tires, $169,500; Ransome & Marles, for ball bearings, $146,500; Birmingham Aluminum Castings Co. and Midland Motor Cylinder Co., $149,300.

A similar petition for the winding up of the affairs of the Harper Bean Co. is opposed by creditors having claims aggregating $2,750,000 and arguments in this case have been postponed for six weeks. This company also is in limited production and while prices of its stock are low they are firm.

The Dunlop Rubber Co. has registered a mortgage to secure $30,000,000 in 8 per cent first mortgage debenture stock payable at 105. The stock is secured by the company's property.

Stinnes Pushes Work at Fiat Tyrol Plant

WASHINGTON, May 13—Negotiations between the Fiat Co. and a German group headed by Hugo Stinnes with regard to the shares of the Alpinen-Montan Gesellschaft, control of which was acquired some time ago by the former, are explained in a communication received by the Bureau of Foreign and Domestic Commerce from Commercial Attache H. C. MacLean of Rome. According to a press dispatch from Vienna, it is stated, the Italian and German groups will exercise a joint control over the company on the following conditions:

"The Fiat will turn over 200,000 shares at a price of 1000 marks each to the German syndicate, which includes the Rhein Elbe Union, the Deutsch Luxembourg, the Gelsenkirchen, the Siemens-Schuckert and the Rochumer Verein, representing a combined capital of over 1,000,000,000 marks. On the other hand, the Fiat will retain 50,000 shares which it has held since 1919. It is said that Hugo Stinnes and Vogler, the general manager of the Deutsch Luxembourg, will become members of the board of directors of the Alpinen Co., and that four German engineers have already left for the Tyrol where the six blast furnaces of the company, only one of which is now active, will be put in operation."

RENAULT BUILDS NEW TRACTOR

PARIS, May 3 (*By Mail*)—Renault, who has specialized on a creeper type of farm tractor since the war, has just put on the market a new four-wheel type machine. The tractor has the same engine as the old type, with four 3.54 x 6.30 in. block-cast cylinders and same thermo-syphon cooling arrangement with radiator placed back of the engine. Transmission to the rear driving wheels is through a cone clutch, three-speed gearbox, and by live axle with planetary reducing gears in the wheel hubs. This type of final reduction has been employed on Renault 7-ton trucks.

South African Show Brings Trade Boom

Dealers Stage Exhibits in Salesrooms After Difference with Agricultural Promoters

JOHANNESBURG, SOUTH AFRICA, March 28 (By Mail)—The annual Johannesburg automobile exposition was held this year in the showrooms of the dealers themselves instead of in the automobile section at the Agricultural Show in Milner Park. All preparations had been made to take part in the fair as usual until it was found that the executives of the Agricultural Society took the position that it was their privilege to let space to certain dealers without reference to the body of motor traders of the city. The dealers thereupon decided to hold their exhibition in their own buildings and the only cars represented at Milner Park were the Nash and the Allen.

The buildings devoted to automobiles were thronged by visitors show week. For a considerable time it has been the contention of many dealers that the advertising value of the show at Milner Park did not repay them for the expenditure involved, and it almost seems that this contention is correct. It is certainly true, however, that numbers of country visitors have lost the opportunity of seeing the different models and in this way the country advertising has not been so widely spread.

The new Wolseley models—10 hp. roadster, 15 hp. touring, 10 hp. coupe and 20 hp. touring—have evoked a great deal of praise, and the exhibit made by the agents, Walker & Co., deserves every credit. The Willys-Knight models on view at the showrooms of Consolidated Motors have been a source of much admiration. The sedan has especially come in for approbation.

The "Silver Queen" (a Buick model in silver) has been the talk of the city. The engine is finished in aluminum and the body in silver. It certainly is a showy piece of work and has been the means of attracting numbers of buyers.

Cars Gain in Popularity

The trade has been experiencing a week of good business, and after the displays are things of the past they hope that the boom in cars will continue. There is ample scope in South Africa for automobiles and the population is coming to a fuller realization of the utility of the internal combustion engine as time goes on.

Only ten years ago the number of cars in this country was very small, but to-day, per head of population, the figurers have increased enormously and out of proportion to expectations. Trucks sales ought to be brisk during the winter months, as the demonstrations at Milner Park have brought home to the farming community the value of fast, efficient transportation. Tractors are being favored and sales are encouraging.

Off to New Start, Maxwell Reduces

Price Cut First Step by Chrysler After Court Confirms Sale —New Officers Named

DETROIT, May 18—The Maxwell-Chalmers reorganization committee, headed by Walter P. Chrysler, came into control of the property of the two companies to-day through confirmation of the sale of the Maxwell plants last week under Federal Court decree.

The first act of the committee after the decision of Judge Tuttle confirming the sale was the announcement of a price cut of $150 on Maxwell cars. This is the second reduction in a year, taking prices back to the 1917 standard. The touring car and roadster now sell for $845, the coupe for $1,445 and the sedan for $1,545. Chalmers prices will remain unchanged for the present.

A. E. Barker, general sales manager, said no announcement would be made of the personnel of the new organization until after the organization meeting of the Maxwell Motor Co., recently incorporated in West Virginia. President W. Ledyard Mitchell remains as receiver of the Maxwell company pending his final discharge.

In confirming the sale and dismissing petitions of R. R. Rogers and H. H. Webb on behalf of themselves and other first preferred stockholders, Judge Tuttle gave the attorneys two options. One of them was to place in control of the court 180,000 shares of class B stock not yet allotted for allocation to the intervenors if it was found they were entitled to a greater share than the reorganization plan gives them. The other option was for the committee to enter its appearance, which would constitute a practical assumption of liability for the protection of protesting stockholders. The attorneys elected to accept the latter plan and entered an appearance for the committee. Judge Tuttle then confirmed the sale. Lawyers for the petitioners intimated that an appeal would be taken but the attorneys representing the reorganization committee regard the confirmation as final.

Executive Offices Busy

Under the plan the new company will have $15,000,000 in new capital, and preparations already are under way at the plant to increase production. The executive offices at the Chalmers plant which have been practically deserted for some time teemed with activity this morning, and representatives of material men swarmed the office seeking new business.

Several changes in the personnel of the Maxwell-Chalmers organization already have been announced. H. C. Reichel, who has been in charge of factory service for Chalmers, has been made service manager for both Maxwell and Chalmers. A. E. Richmond, for several years in charge of Maxwell service at the factory, has been appointed supervisor of the San Francisco district for Maxwell-Chalmers. R. E. Thompson, former chief inspector for Maxwell-Chalmers, has been made special sales supervisor for both companies, with temporary headquarters at Detroit. Theodore Koerner has been named superintendent of inspection, having general charge of inspection in all Maxwell-Chalmers plants, and Leonard Vandersall, who for the last seven years has been connected with the company, has been made South African special representative for the export department. Mr. Vandersall sailed for his new territory May 12.

Dort Drops Prices as Costs Decrease

DETROIT, May 17—The Dort Motor Car Co. announces a price reduction ranging from $100 to $180 effective today. Touring and roadster models are reduced from $1,215 to $1,115, coupe from $1,865 to $1,685, and sedan from $1,995 to $1,835.

"These reductions are on the new model introduced in January," said J. D. Mansfield, general sales manager, "as the new Dort is not a pre-war car and we are not trying to establish pre-war prices for there is not a pre-war standard from which to judge these new models. The reduction is due solely to the fact that we have reached a production basis that enables us to operate on a lower overhead per car built."

Hupp Prices Reduced $200 to $325 a Car

NEW YORK, May 16—Effective today prices on Hupmobile cars are reduced $200 to $325, the smaller cut being made on open models and the larger on enclosed. Under the new scale of prices the roadster and five-passenger cars are reduced from $1685 to $1485; the coupe from $2725 to $2400, and the sedan from $2800 to $2485.

STERLING PRICES REDUCED

NEW YORK, May 16—Prices on Sterling tires and tubes have been reduecd 15 and 20 per cent, the minimum cut being made on Ford size fabric tires, and the 20 per cent reduction being made on all other fabric and cord tires, and on gray and red tubes.

FUEL PRICES HELP BUSINESS

NEW YORK, May 16—The leadership of the oil companies in reducing prices is being hailed in motor circles as a basic move in reconstruction which will permit lower costs of doing business. With 60 per cent of the total gasoline consumed used for business purposes, it is pointed out that fuel prices have a direct bearing on the cost of doing business. With refineries closing down for lack of business it is regarded as a certainty that lower prices will continue to reign indefinitely in the gasoline field.

VerLinden to Join Durant Enterprise

Will Resign Presidency of Olds Units of General Motors—Noted as Executive

DETROIT, May 18—The General Motors Corp. announced to-day that Edward Ver Linden has been relieved of his duties as general manager of the Olds Motor Works and that A. B. C. Hardy has been appointed acting general manager. Hardy is one of the veterans of the General Motors organization and has held many positions of responsibility.

DETROIT, May 18—Edward VerLinden soon will retire from the presidency of the Olds Motor Works at Lansing to join forces with W. C. Durant, it has been learned here. His resignation has not been filed and no date has been fixed for his departure from the General Motors organization.

Details of VerLinden's future plans are not obtainable but he will head a motor plant which will be established in Lansing to build engines for the Durant four-cylinder car. The Durant car, at the beginning, will be largely an assembled product and it is probable Continental motors will be used until the production of engines begins at the Lansing plant.

VerLinden resigned as superintendent of the Buick Motor Co. nine years ago to become works manager for Olds. Two years later he was made general manager and a short time later was promoted to the presidency. When he joined the Olds organization the output was 2000 cars a year and the plant is now producing about 40,000 cars a year. The factory has been rebuilt and re-equipped under VerLinden's management and more than $12,000,000 has been expended in bringing it up to its present efficiency. The factory is equipped to build two new models and now has on hand orders sufficient to permit operations on a basis nearly normal for some time to come.

Under the management of VerLinden, the Olds company frequently has led all other units of the General Motors organization and the Oldsmobile rivals Buick and Cadillac in popularity.

R. H. Collins has definitely severed his connection with the Cadillac Motor Car Co. and is devoting his attention to the formation of the Collins Motor Car Co. H. H. Rice has assumed complete direction of Cadillac affairs.

UNITED CUTS BODIES AGAIN

CLEVELAND, May 16—United Automotive Body Co. has made a reduction of 25 per cent in prices on its products, the reduction being the second of its kind within four months.

Exchange Hurts Car Sales Abroad

Need for Stability Is Shown by Hoover

French and British Makers Combat American Competition —Other Markets Poor

WASHINGTON, May 19—Evidence of Secretary of Commerce Hoover's intention to develop foreign markets for American automotive products is given in an official report compiled to-day from questionnaires sent to commercial attaches in European countries, concerning the general economic conditions with special reference to automobiles. The first of a series of reports indicates that the exchange problem is one of the greatest difficulties confronting American automotive exports. American agents abroad reported that foreign manufacturers have not increased production to any great extent because the present economic, financial and industrial depression had affected demand.

The first section of the report issued to-day dealt with automobile markets in France, Italy, England, Belgium, Austria and Czecho-Slovakia. While large American exporting firms have an intimate knowledge of the French market, the official report of Commercial Attache W. C. Huntington is of importance. He stated that the price will be of greater importance in the future and as a consequence French manufacturers are adopting standardization. Domestic manufacturers offer a very formidable competition but American automobiles have become very popular since they were put in general use after the army sold the surplus stocks to the French Government. The size of the average French farm prohibits large sales of tractors.

American Light Trucks Sell

The commercial attache at London reports that the best seller on the English market is a medium sized car of 12 to 18 hp. R.A.C. rating, and fully equipped. There has been a brisk demand for American trucks of 1 to 1½-ton capacity. British manufacturers are doing their best to offset this competition by producing a truck of this kind. They are also beginning to use the pneumatic tires. Because of the exchange situation, the terms usually sought are cash. There is comparatively little demand for tractors and the competition from British manufacturers is very keen.

The exchange is very unfavorable for American cars and the products of local factories in Belgium. Twenty-five per cent of the cars now operated in Belgium are of domestic origin. The Belgian manufacturers are reported for the most part secure financially, although the capital of their factories is low. The Belgian cars are firmly built to withstand the excessive vibration caused by the cobble stones on the highways, so that they are better fitted for local usage than the imported car. Owing to the present rates of exchange any advantage in price which the American car selling between $900 and $2,000 might possess over the native product has vanished. The Department of Commerce was advised that a recession of the dollar exchange to ten francs would undoubtedly allow American producers to undersell the domestic manufacturers. It is reported that a Fiat chassis can be bought for 18,500 francs. A 10-horsepower Renault complete with solid wheels sells in Belgium for 2200 francs.

Belgium Short on Cash

Belgian manufacturers have fallen down in their efforts to perfect their sales organization. It is customary to furnish dealers with chassis or complete cars on a commission basis, and these vehicles are paid for when sold. The average automobile dealer in Belgium has not a large amount of capital, and therefore must be financed to some extent by the factory or the distributor. If the distributor has subagents, he usually takes 25 per cent of the price and allows the subagent 10 or 15 per cent. Credit sales are made on the basis of 3 and 6 months' notes, but the natural preference is for cash. Tractors are used on the large farms in this country with good results but owing to the small size of the majority of Belgian farms, the market of the tractor will always be limited.

A number of important factors govern the sale of American automotive products in Italy. The radical increase in import duties on motor vehicles has a tendency to prohibit the development of this market. The internal taxes are so heavy that it is practically impossible

(*Continued on page 1087*)

AUTOMOTIVE PRODUCTS $2,000,000,000 IN 1919

WASHINGTON, May 14—Official preliminary production statistics compiled by the Census Bureau show that 312 factories in 1919 produced automobiles worth $1,181,659,000, or more than double the figure shown by the 1914 census when 300 producers manufactured products worth $503,330,137.

Products worth $567,655,200 were turned out in 1919 by 1879 manufacturers of bodies and parts. The total value of automotive products in 1919, therefore, was nearly $2,000,000,000.

Cleveland to Skip August Depression

Usual Slack Period to Be Overcome by Late Demand, Says Grant Official

CLEVELAND, May 16—The automobile industry, which has been doing more than any other production medium to restore normal conditions in this city, is now to have help from other lines.

The Cleveland Trust Co., after a careful survey, reports that genuine improvement in all lines of business has set in during the month. The reasons for it are lower interest rates here and abroad, better conditions in the Federal Reserve and State and national banks, decreased unemployment, greater activity in all important lines such as automobiles, rubber, textiles, shoes and leather; increased car loadings and greater railroad earnings, stock market advances and greater participation by the public, far-reaching wage agreements in important industries, increased building construction, brighter prospects for reparations agreement, and the rise in value of money of European countries. The last two reasons are considered especially important to all lines of industry, particularly the automobile producer, for they are considered a forerunner to an expansion of foreign trade.

George W. Hubbs, of the Grant Motor Car Co., whose company has moved forward steadily since the first of the year in production and net earnings, predicted that what some term as the annual slack period in August will not be experienced this year. He says that the general business revival, as seen by the Cleveland Trust Co., coming at this time of the year, is certain to continue right through the summer.

"Production of automobiles has been low for many months," said Hubbs. "That fact, coupled with the steady improvement in all lines of business, is certain to keep the automobile factories going through the summer months."

Credit Stringency Passed

The Cleveland Trust Co. says that so far as the Cleveland district is concerned the credit stringency has passed. Automobile producers, as well as leaders in other lines of business in this city, have organized for a movement that has been developed to increase foreign trade here.

Walter C. White, president of The White Co., and C. W. Mears, who handles the advertising for the Winton Motor Co., are members of an executive committee that has been formed to push the sale of stock in the Foreign Trade Financing Corp.

Industry Asks "Stigma Tax" Repeal

Excise Tax Unfair, Senators Are Told

Strong Arguments Presented to Finance Committee by Graham and Hanch

WASHINGTON, May 16—Congress has received the tax program of the automotive industry which was offered for its guidance in internal revenue revision. Spokesmen for the industry impressed upon the Senate Finance Committee to-day the utility of motor vehicles and the urgent need for relief from the oppressive and discriminatory burdens of taxation. While members of the Committee criticized and questioned many of the suggestions for fiscal legislation they indicated that they had a new vision of the magnitude and importance of the automotive industry and its relation to the political and economic structure of the country.

Distinguishing the present mode of taxation, as it applies to the automotive industry as "stigma taxes," had its effect for it revealed to the Senators the inequities under which the automotive industry struggled back to new levels of industrial activity. There were unmistakable evidences of the hostility of Senators to the proposal that the excise tax should be abolished. Their opposition was apparently founded on the supposition that such abolition would pass the burden of highway maintenance upon all classes without distinction as to the users of these arteries of commerce.

Representatives of the industry impressed the Committee with the fact that the highways were now in general use and not confined to motor vehicles, although automobiles bore the entire expenses of maintenance, and in some cases cost and construction.

Shows Suppressing Effects

George M. Graham, vice-president of the Pierce-Arrow Motor Car Company, and a member of the Taxation Committee of the National Automobile Chamber of Commerce, limited his presentation to the specific effects of the present tax system upon the automobile industry. He appeared also for the Motor and Accessory Manufacturers Association. Criticizing these levies as "stigma" taxes served its purpose for it constantly brought to the mind of his auditors the fact that the industry was singled out for heavy and iniquitous assessment. He illustrated the effect of such taxation by comparing them to such regulatory taxes as are levied on liquors, narcotics, dirks and dangerous weapons, the purpose of which was to regulate or even suppress, rather than encourage, the use of such products.

CAR TAX SENSELESS, SAYS NEW YORK TIMES

NEW YORK, May 14—In an editorial discussing the "shocking" methods employed by the Government to obtain its revenues, the New York *Times* takes issue with the tax proposals of Secretary of the Treasury Mellon. In this connection it says:

"He would increase stamp taxes and, strangely enough, proposes a license tax on the use of automobiles. The automobile is no longer a vehicle of pleasure. It is a common conveyance, necessary to the business man, the professional man and the farmer. Such a tax would be as senseless as one levied upon a farmer's horse and wagon or upon his oxen and cart."

Graham made an effort to disabuse the minds of the Senators as to the term "non-essential" and its application to the industry. He said that at the time it was originated preference in the matter of materials, transportation and labor was given to industries most essential to war activities, but that time had passed.

"We cannot feel that the motor car and the motor truck can be fittingly rated in any classification whose value to the public is questioned," Graham said. "During the discussion of the two previous revenue bills, the opinion was openly expressed that if the increased taxation on passenger cars should curtail their use it would be an excellent thing. Many gentlemen may have felt this with great sincerity during the war period; that they continue to think so now I should seriously doubt.

No Standing if Luxuries

"If the passenger car and motor truck are luxuries we must expect to be rated among the most heavily taxed industries. We have no standing here. But if they are luxuries, then the President of the United States is wrong, for he has placed the stamp of essentiality on cars and trucks. In his first message to Congress he made the very definite statement, 'The motor car has become an indispensable instrument in our political, social and industrial life.'"

It was his contention that a tax on motor vehicles was definitely a tax on transportation. His statement that the railroads have a monopoly after rights of way are constructed was challenged by Chairman Penrose. Graham made it clear that there were no Federal taxes on other units of transportation and

Ford to Continue 4000 a Day Output

Report of Shut Down July 1 Denied—Company Straining to Meet Orders

DETROIT, May 18—In denial of reports that the Ford Motor Co. would shut down July 1, officials to-day said the company was far behind in orders and straining every energy to stimulate production to meet demand. As a result the company now is building more than 4000 cars and trucks daily and has been for more than a week. The record for production reached Oct. 20 last year still stands but the plant has been increasing its output almost daily for the last two weeks.

On May 3 the cars and trucks built numbered 3860 and the following day production reached 3992. Two days later the plant ran over the four thousand mark with 4032 cars and trucks and on May 9 turned out 4072. The following day it built 4083. The number for the record day last October was 4688.

The tractor plant also is running at full speed and the ten thousandth tractor was turned out May 3.

This work is being done with a force of about 40,000 men as compared with approximately 60,000 a year ago. The company now is paying a bonus each pay day instead of at the end of the year. It averages about $3 a week per man.

Slough Trading to Sell Trucks in South America

(*Continued from page* 1078)

duce the established time by something like 50 per cent, contrary to a clause in the national agreement.

Opposition to the anti-dumping legislation proposed by the Government is becoming more active and threatens to jeopardize the Coalition ministry because of the defection of the free traders. One of the features of the proposed legislation which is causing the greatest opposition is the plan to protect British industry at the expense of countries like France and Italy, which have a low rate of exchange.

Now that the price fall is in full swing there will be still greater difficulty in keeping out American products. The buying public is becoming more insistent on knowing why it is possible for American manufacturers to beat the British maker in his own market while contributing 33 per cent to the British Government for the privilege of doing business in that country.

Slough Trucks Here for Sale in U. S.

Truck Company of America Lands 2000—To Sell at Half List Price

NEW YORK, May 19—The Truck Co. of America has been organized by L. Mansbach of the Fidelity Motor Supply Co., I. Edward Roskam of the Roskam-Scott Co., and A. B. Messing of New York, and Morris Froelich of Chicago, to deal in American made motor trucks which will be reimported from England. It is understood the new company has purchased approximately 3000 of these trucks from the Slough Trading Co., Ltd., of London which bought them from the British government. Two thousand of the trucks are now in this country.

The trucks, it is stated, will be sold at approximately 50 per cent of the list price. Among the makes included in the purchase are Pierce, Mack, Packard, White, Riker, Locomobile, Liberty, Peerless, F. W. D., Nash and E. M. C. In addition to the trucks the company proposes to import a large quantity of parts for replacement purposes and also accessories of American make.

The company proposes to offer dealer franchises throughout the country and to advertise extensively.

Roskam has been the New York representative of the Slough Trading Co. since it began reimportation of these trucks into the United States. The first large shipment was sent to the Pacific coast but the demand for them was not heavy. It is now believed that with general business conditions approaching a more normal basis there will be an increased demand for these trucks.

The company has leased a building with 45,000 sq. ft. of floor space on the ground floor in 56th Street between 10th and 11th Avenues as well as a warehouse with 35,000 feet of space and a three story office building in West 63rd Street.

It is stated that the company will have an export department with representatives in various foreign countries to offer foreign buyers trucks in large quantities. An especial effort will be made in this country to develop business with road builders.

NASH BUILDS 2½ TON TRUCK

KENOSHA, WIS., May 14—The Nash Motors Co. has brought out a 2½ ton truck which is especially adapted to highway construction work. Its general specifications are much the same as the present 2-ton model, 3018, except that the springing has been made heavier, the wheelbase shorter and some other minor changes have been made to allow for the heavier loads. The price, f.o.b. factory will be the same as the 3018, $2550. The wheelbase is 121 in. and the space back of the driver's seat about 97 in., this of course depending on the style of body used. Pneumatic tires may be fitted.

OVERLAND ANNOUNCES "SMASHING" PRICE CUT

TOLEDO, May 19—A "smashing price reduction" will be announced by the Willys-Overland Co. in display advertising in the leading newspapers of the country Sunday morning. No information is available as to the range of reduction and a decision on the subject was not reached until yesterday.

C. R. I. & P. Files Protest of Bus Use of Highway

SPRINGFIELD, May 14—The Chicago, Rock Island & Pacific Railway Co. has filed a protest with the State public utilities commisssion objecting to the use of Illinois' hard roads by motor bus companies as an "appropriation of public improvement to private interest." The protest is directed against the Peoria White Star Bus Co. and the Ivy Way Bus line which the railway complains will force it to curtail its service.

The railway company declares that it already provides sufficient service in operating four trains each day

"The Chicago, Rock Island & Pacific Railway Co.; as a large taxpayer," the complaint says, "protest against the use of the improved hard roads of the State, recently built at a great cost, by common carriers for hire by automobile and autotomobile truck, and states the use of said highways by such common carriers amounts to a substantial appropriation of a public improvement by private interests, and for private purposes to the great annoyance and detriment of the public in general.

"The railway company further says the use of said highways by such carriers, who are accustomed to employ large, heavy and cumbersome vehicles, will result in the speedy disrepair, deterioration and destruction of said highways, and without any compensation from the private enterprises so using and abusing them."

EIGHT INDUSTRIES SHOW GAINS

WASHINGTON, May 18—Increased employment in eight major industries is shown in Labor Department figures for April. The largest increase was 25.2 per cent in the automotive industry. The others which showed increases were woolens, hosiery and underwear, men's clothing, silks, cigars, cotton finishing and boots and shoes.

PAIGE TO MAINTAIN PRICE

DETROIT, May 17—Paige Motor Car Co. has sent a notice to its dealers that there would be no price reduction now and none in the near future. President Jewett said he did not believe in guaranteeing prices but there was nothing in the cost of manufacture to justify any price reduction in so far as his company was concerned.

Automotive Activity Grows in Milwaukee

Passenger Car Engine Makers at Capacity — Truck Engine Makers Report Gains

MILWAUKEE, May 16—It has been especially gratifying to commercial, industrial and civic organizations of Milwaukee to be informed by governmental sources that one of the reasons that Milwaukee is one of the few large cities of the country showing an increase in number of men employed is the steady expansion of production in the automotive industries. This increase is being accentuated day by day by the reemployment of men who were laid off months ago, as well as the extension of working schedules of men who were retained at reduced hours.

Engine manufacturers specializing in passenger car power units are now operating at capacity, with several reporting overtime schedules in some departments. Makers of heavy duty engines for trucks and tractors are doing better, especially the former. Employment in service and repair shops continues to increase, due to the necessities of a situation in which used cars taken in trade are more numerous than ever before and buyers of renewed cars insist that the mechanical condition must be first class.

The merchandising of passenger cars continues to proceed very satisfactorily in Milwaukee and vicinity. Business is losing the spotty character of recent months. Sales are made with more freedom and cover the entire range of price classifications rather than the cheapest or the higher-priced vehicles, as before. It is noted, however, that the announcements made during the first two weeks of May by numerous manufacturers concerning price reductions has had an influence upon a good many prospective buyers who were considered the livest kind of prospects but suddenly resisted further sales effort on the plea that they intend to await developments in respect to future prices.

This has caused many dealers to offer on their own responsibility or by arrangement with maker and distributor to protect buyers to July 1 or even Aug. 1. Used car sales have been stimulated by special sales conducted by numerous big dealers.

FIRE DAMAGES STUTZ PLANT

INDIANAPOLIS, May 14—Production at the plant of the Stutz Motor Car Co. here will be seriously crippled for six weeks because of a fire in the warehouse of the plant late yesterday. The damage has been estimated at $100,000. He said it would be more than a week before the stock could be removed from the warehouse and the damage correctly estimated. The fire started in some cotton trimmings on the third floor of the four story building and serious water damage was sustained.

Exchange Rates Hurt Car Sales Abroad

Taxes Discourage Sales in Italy—Austrian Factories to Build 800 Cars in Year

(*Continued from page* 1084)

to sell to any class but the rich. The policy of the Government had been to discourage the use of motor cars. A heavy graduated tax was imposed not long ago, running from 2850 lira on low-powered cars to 1500 lira on cars rated at over 50 horsepower. There are not many medium or low-priced American cars imported and the Fiat company is reported producing 60 cars per day with an anticipated production of 200 cars per day when their new factory is completed. The Italian industry has always been dependent to a large extent upon export business. The Italian farmer has not been educated to a point where he can readily be persuaded to purchase tractors.

The economic conditions in Austria discouraged the purchase of motor cars. It is doubtful whether more than 800 cars will be produced during the current year in Austrian factories which have a capacity of from 20,000 to 25,000 cars a year. The depreciation of the Austrian currency is so great that it practically removes the element of foreign competition, inasmuch as the cost of foreign cars is too high for purchase by Austrians. American foreign agents state that if large amounts of foreign capital should be invested in Austria in the production of motor cars, the same circumstances would react to the disadvantage of the local manufacturers, as a comparatively small investment in sound currency would create a large capital in Austrian currency. Austrians are not willing to abandon their draft horses.

American cars have gained popularity in Czecho-Slovakia, particularly of late when the adverse exchange has made the low-priced cars the best sellers. There has been a demand for four and five-ton trucks. Shipments of American goods have been made via Hamburg because of the convenience of river transportation down the Elbe to Prague.

To Confer on Exports

NEW YORK, May 17—At the request of Herbert Hoover, a committee headed by J. Walter Drake has been appointed by President Clifton of the National Automobile Chamber of Commerce to confer with the Department of Commerce. The other members of the committee are: Arthur Waterfall, vice-president, Dodge Brothers; E. A. Williams, Jr., president, Garford Motor Truck Co.; Alfred H. Swayne, vice-president, General Motors Corp., and Percy Owen, president, Liberty Motor Car Co.

FRANCE HOLDS USED CAR FAIR

NEW YORK, May 16—Details have been received here of the used automobile fair which will be held at Limoges, France, May 23 and 24. The fair is being organized by the Automobile Club of France and none but used machines will be admitted to the grounds. On the first day, sales will be conducted by private negotiations but on the second day there will be an auction for owners who wish to dispose of their cars in this way. Limoges has been chosen by the fair not only because it is centrally located but also in order that the cars which will be for sale will be in good condition because they will have to travel there under their own power.

Motor Vehicles Gain in 1920 Transportation

NEW YORK, May 16—Statistics compiled by the National Automobile Chamber of Commerce show that automobile passenger travel neared the five billion mark in 1920. Fully 4,932,000,000 persons were carried by motor cars during this period, as compared with the 1,234,222,889 revenue passengers of the railroads.

Motor trucks hauled 1,200,000,000 tons of freight, or nearly half the amount carried by rail lines, which totalled 2,504,000,000 tons.

The growth of the automobile business has not been competitive with the railroads, however. Much of it is directly tributary, as in bringing both passengers and freight from farm to train, and in suburban service to cities. Another large field for highways transport when not directly tributary to railroad is the travel from point to point over short haul distances where there is no other means of communication.

The motor car passenger figures increased 400,000,000 during 1920 due to the gain in motor vehicle registration. At the same time the railroads showed a gain of 60,000,000 revenue passengers.

REMY TO WELCOME S. A. E.

ANDERSON, IND., May 16—Remy Electric Co. will hold open house at its factory on May 22 and 23, the dates of the summer meeting of the Society of Automotive Engineers, at West Baden. In sending out invitations to the engineers to visit the factory, the company points out that it is mid-way between both Detroit and Chicago and the meeting place and that "good old Hoosier meals" will be served those stopping over. Automotive manufacturers in all parts of Indiana are planning to extend hospitality to the visiting delegates.

TO REFUND BEARINGS TAX

NEW YORK, May 17—The Motor and Accessory Manufacturers Association has been informed by the Commissioner of Internal Revenue that manufacturers of bearings and bushings who have paid taxes on them as automobile parts or accessories when they had not been manufactured to specification or solely for use in motor vehicles are entitled to refunds on taxes paid since Feb. 25, 1919. These refunds will aggregate many thousands of dollars.

METAL MARKETS

EVEN amid the from day-to-day buying which constitutes the only form of activity in the steel market just now, purchasing agents feel the ground sliding from under the prices that a few weeks ago were proclaimed in certain quarters as "stabilized." In fact, conditions are parallel to those that prevailed previous to the last reduction in the leading interest's price schedule. The steel mills that succeed in obtaining what orders for small tonnages are available characterize their shading of prices as special concessions on desirable business. Their unsuccessful competitors call it price cutting. Far from being extraordinarily pleased with their purchases, the buyers of these odd tonnages almost invariably regret that they could not postpone placing their orders, feeling that had they been able to do so they could have saved money. Meanwhile active preparations against the coming of lower prices are being made by producers. One of the largest "independents" in the Youngstown district has taken the lead in abolishing the eight-hour day as a basis for wage computation, and hereafter straight time on an hourly basis will be paid. Other "independents" are following suit. On the basis of the last bi-monthly wage settlement between the Amalgamated Association of Iron, Steel and Tin Workers and the Association of Independent Sheet and Tin Plate Manufacturers, the conversion charge for No. 28 gage black sheets has been reduced to $17.11, which compares with $24 when sheets were on a 5.80c. card. Numerous operating economies are being instituted and result in steadily diminishing production costs. Unless the leading interest anticipates the evolution of a lower market by another cut in prices, the industry faces another period of slowly sagging values, and the uncertainty that attends such a condition is alike unsatisfactory to the purchasing agent and to the producer. Representative business will not be placed until the situation has clarified further, and what odd lot buying will be made necessary by immediate requirements will be a matter of individual negotiation in which "publicational" quotations will form a basis for concessions.

Pig Iron.—Were it not for accumulations of resale iron still pressing on the market its liquidated character in point of production and prices would be highly impressive. The melt in Middle West foundries is slowly increasing, due to foundry crafts being in a more reasonable frame of mind. With Foundry No. 2 selling at $23.30, valley, automotive foundries would be disposed to contract for a reasonable time ahead, were it not for the hand-to-mouth buying of automotive castings by passenger car and truck builders.

Steel.—The $39 price for sheet bars has apparently once more gone by the board, and non-integrated sheet mills could probably shade this figure fully $2 on representative orders. Youngstown automobile sheet makers are once more disgruntled over the paucity of orders. Cold rolled strip steel continues to be inquired for in modest quantities by the automotive industries, but concessions are asked in price. Bolts and nuts are in better demand, with the Ford Motor Co. figuring as purchaser in the Chicago market. Heavy forgings are also more actively sought by automotive builders.

Aluminum.—The market still waits for activity on more definite news from Washington regarding the outlook for a higher tariff.

FINANCIAL NOTES

International Motor Truck Co. reports net profits for the quarter ended March 31, 1 of $4,396. Present incoming business justifies an expectation of deliveries for the present quarter at the rate of 6000 trucks per annum. Net profits for the first half should show preferred dividends fully earned. The company has net working capital in excess of $19,000,000 and a cash balance of more than $3,000,000. The company has reduced inventories since Jan. 1 about $1,500,000.

Parish & Bingham Corp. reports sales for the first four months of 1921 as representing 41.14 per cent of sales for the corresponding period in 1920. The plant has been operating daily since Jan. 15 and maintained an average of 24.53 per cent of men employed. Releases scheduled for May are considerably in excess of $600,000 and additional releases are being received daily.

Stewart-Warner Speedometer Corp. reports net earnings for the first quarter ended March 31 of $50,527. Payment of a dividend of $1 a share, or $395,000, made it necessary to draw on surplus for nearly all of that amount, reducing the surplus to $6,697,86 compared with $8,092,865 on Dec. 31 last.

Marion Tire & Rubber Co. will increase its capital from $750,000 to $1,250,000, the additional capital to be used in broadening the activities of the company. C. J. Davis of Cleveland has been elected president and general manager of the company.

Elgin Motor Car Corp. for the year ended Dec. 31, 1920, shows that total sales were $7,383,606, as compared with $6,479,100 in 1919. Net profits for the year 1920 amounted to $195,908, a considerable increase over earnings of the previous year.

INDUSTRIAL NOTES

Minneapolis Steel & Machinery Co. has moved its New York offices from the Tribune Building to the Woolworth Building. The main export offices of the company will in the future be located at the factory in Minneapolis. C. W. Hadden, manager of foreign sales, will make his headquarters at Minneapolis. J. A. Teach will continue in New York as contracting engineer and designer for the domestic and export trade.

Essenkay Products Co., Chicago, has leased from the Chicago Consolidated Brewing & Malting Co. a two-story building for ten years at a term rental of $85,000. The property will be remodeled at a cost of $150,000 and used for general offices, salesroom and factory.

Hilbert Mfg. Co., Hilbert, Wis., and Mullins Mfg. Co., Brillion, Wis., both makers of farm equipment, have been consolidated as the W. M. Mullins Mfg. Co., with $200,000 capital. The Mullins company will remove its plant equipment to Hilbert, which plant will be enlarged.

Lansing Bus Co., Lansing, Mich., has been organized to distribute special bodies for all makes of truck chassis, the bodies to be placed with truck makers for mounting on chassis at buyers' orders. Fred L. Waite will be manager of the new company.

REES TO BUILD FREIGHT CAR

COLUMBUS, May 14—The Rees Motor Co., with headquarters in the Commerce Building, has been re-incorporated with an authorized capital of $300,000 and will soon locate a factory for the manufacture of the Rees automobile, a two litre high-grade car weighing 1850 lb. J. H. Rees, the originator of the car, has spent six years experimenting and solving the problem of producing a light car.

One of the features is the system of spring suspension. A specially designed carburetor is also featured. Rees is president and general manager; J. L. Stanton, vice-president; S. W. Moiselle, secretary and M. R. Slayback, treasurer.

Develop Steam Car to Sell at $1000

INDIANAPOLIS, May 13—A 5-passenger steam car to sell at $1,000 is being developed by George A. Coats, head of the Coats Machine Co. of this city. The power system is the invention of a Norwegian engineer who came to this country during the war to investigate the development of internal combustion engines here. The car will have a 110 in. wheelbase and will be equipped with electric lighting and an electric fuel heating outfit for starting.

The boiler of the new car is of the combined fire tube and water tube type and goes under the hood. An advance over previous practice in light boiler construction is said to consist in the top and bottom welding of the boiler tubes. There are really two engines arranged in a single unit and mounted directly on the rear axle, each engine driving one of the axle shafts, so that no differential gear is required. The housing of each half of the axle carries three fixed cylinders, set 120 deg. apart. These cylinders are of the single acting, poppet valve type. They have a bore of 2¾ in. and a stroke of 3 in.

The three connecting rods of each engine connect to a crank pin integral with the drive shaft of each wheel, thus dispensing with all gearing. With a car speed of 40 m.p.h. the engine turns at 500 r.p.m. Kerosene is used as fuel and 1 gal. is said to be sufficient for from 20 to 40 miles, the exhaust is condensed and one filling of the water tank gives a mileage of 300 to 500. It is planned to manufacture a light truck for delivery work on the same chassis.

KNOX TIRE OFFICERS INDICTED

MT. VERNON, OHIO, May 16—Five officers of the Knox Tire & Rubber Co. have been indicted on charges of violating the blue sky law. The men indicted are R. E. Frantz, president; S. D. Spencer, secretary; V. V. Hendershott, E. Scott Cannell and C. B. Carpenter, members of the board of directors.

COLLINS BUYS ONE BUILDING

DETROIT, May 16—R. H. Collins has purchased only the main building of the old Cadillac factory here and not the entire plant as announced last week. The various other buildings are retained by the General Motors Corp.

BANK CREDITS

Written exclusively for AUTOMOTIVE INDUSTRIES *by the Guaranty Trust Co., second largest bank in America*

NEW YORK, May 19—The local call money market showed a firmer tendency last week after opening at 6½ per cent on Monday. The following day and until Friday, when a 6½ per cent renewal rate was again quoted, the ruling rate had been 7 per cent. The firm tone was probably due to the anticipation of the shifting of funds at the opening of the present week incident to government operations and to the payment of subscriptions due on the $230,000,000 Northern Pacific-Great Northern issue.

On Monday of this week interest was due on the second 4 per cent Liberty Bonds and the second 4¼s, and there was due $232,124,000 of Certificates of Indebtedness. At the same time, the Treasury Department was to bring forth a $200,000,000 5½ per cent issue. Following the easy tone in the early part of the week, rates for sixty and ninety days' and four months' paper stiffened to 6½ to 6¾ per cent. Five and six months' paper was unchanged at 6 to 6½ per cent. There was moderate trading in the time money market, with few important transactions.

The mid-week statement of the Federal Reserve System showed another increase in gold reserves and a further reduction in Federal Reserve note circulation. These two factors were mainly responsible for the improvement shown in the reserve position of the System. The ratio of total reserves to deposit and Federal Reserve note liabilities combined increased from 55.3 per cent to 55.9 per cent—the highest ratio since August, 1918.

The April figures for our foreign trade show a continuation of the decline which has been characteristic of recent months. Exports for the month were valued at about $340,000,000, as against $386,800,000 in March, 1921, and $684,700,000 in April, 1920. Imports at $255,000,000 mark an increase of approximately $3,000,000 over the March figures, but a decrease of $240,700,000 from the figures of the corresponding month a year ago. Exports were the smallest for any month since January, 1916, and the excess of exports amounted to only $85,000,000. Exports of gold for the month totaled only $400,000, while gold imports amounted to $92,000,000. The inflow of gold has continued at about the same rate during the first two weeks of May.

The Dallas Federal Reserve Bank has just announced a reduction of its discount rate from 7 per cent to 6½ per cent. This means that six of the Federal Reserve banks now have a 6 per cent rate on commercial discounts, and four have a 6½ per cent rate. A significant ruling of the Federal Reserve Board is that made at the close of last week regarding the eligibility of six months' bankers' acceptances in import and export transactions. Under a new regulation, this type of paper becomes eligible for open market purchase by Federal Reserve banks.

MEN OF THE INDUSTRY

A. H. Bartsch, general sales manager of the American Bosch Magneto Corp., has returned from a two months' trip of 10,000 miles, during which he visited service stations and distributors in the South, Southwest and on the Pacific Coast. He reports that nearly everywhere greater effort is required to get business, but that service stations are conducting intelligent and aggressive sales campaigns. Most Bosch service stations now are handling the new shaft drive Bosch magneto attachment for Ford cars and Fordson tractors.

E. A. Blake has been appointed service engineer of the Transport Truck Co., Mt. Pleasant, Mich. Before joining Transport he was assistant superintendent of the Republic Truck Sales Corp.'s engine division at Alma, Mich. He has also been in the engine department of Curtiss Aeroplane Co., Inc., and before that was with Maxwell and Standard.

Fred G. Whipple, division sales manager for the Service Motor Truck Co., Wabash, Ind., has been appointed sales manager in California, Arizona and Nevada. Walter Dix, formerly of the Packard Motor Car Co., has been appointed to succeed Whipple in Maryland and Virginia and parts of Delaware and North Carolina.

Louis E. Clarke, who for several years has been connected with the manufacturing department of the Hoyt Metal Co., both in the East and the Middle West, has been appointed sales manager of the babbitt-lined bronze bushings and die casting departments, with offices in the Boatmen's Bank Building, St. Louis.

Frederick P. Nehrbas has become associated with George A. Weidely as works manager of the Weidely Motors Co., Indianapolis. Nehrbas has been connected with the industry since 1900, having been with E. R. Thomas Motor Car Co., Alco, Lyons-Atlas Co., and latterly with Premier.

Frank E. Wodell, assistant sales manager of the General Motors Export Co., has been given a leave of absence of six months to rest after eleven years of activity with General Motors, the last eight with the export company. Wodell will spend his leave on camping trips in the Rockies.

E. J. Shassberger has been named advertising manager for the Olds Motor Works, succeeding Thomas O'Brien, who has been promoted to assistant sales manager. Shassberger has been with Olds about four years in the sales department and was assistant to O'Brien.

O. C. Berry has joined the staff of the Wheeler-Schebler Carburetor Co., Indianapolis, as chief engineer. He was formerly professor of automotive engineering at Purdue University and research engineer for the Hupp Motor Car Corp.

Paul E. Ryan has been appointed sales manager of the Templar Motors Corp., Cleveland, succeeding Harry Anderson. Ryan was formerly with the Aluminum Castings Co., Perfection Spring Co. and the National Acme Co.

Jay Dewey, general sales manager of the Lexington Motor Co., will spend the balance of the year on the Pacific Coast directing sales activities in that section.

J. A. Callahan, vice-president in charge of production of Martin-Parry Corp., Indianapolis, has been elected vice-president and general manager of the company.

H. H. Crawford will be special representative for the Gier Tuarc steel disk wheel in the territory of Michigan, Illinois, Indiana, Wisconsin and Ohio.

Warren D. Oakes, president of the Oakes Co., Indianapolis, will sail for Europe June 1, to establish agencies in Belgium, Scotland, England and France.

C. E. Pumphrey has resigned as sales manager of the McGraw Tire & Rubber Co. and has been succeeded by W. H. Hurley, assistant sales manager.

Charles E. Speaks has been appointed European manager for the Firestone Tire & Rubber Co., with headquarters in London.

Norman DeWind, originator of the motor road roller, has severed his connection with the Austin Mfg. Co., Chicago.

Ford Dealers Combine for Used Car Disposal

CINCINNATI, May 23—Automobile men over the country are showing much interest in a plan that is being tried out by the Ford dealers in the Cincinnati territory, who have organized the Ford Dealers Corp. with a capital stock of $75,000 to handle the sales of used Ford cars in this territory.

The stock is divided equally among the 14 authorized Ford dealers in the three counties—Hamilton County, Ohio and Kenton and Campbell countries, Ky., just across the river from Cincinnati.

The purpose of the corporation is to handle used Ford cars which are offered in exchange for new cars, and, hereafter, when a man with an old model wishes to trade it in on a new car, he will be referred by the dealer to the corporation, where a cash sum will be offered him for the machine. The corporation will, in turn, dispose of the machine through the usual second-hand methods. This will permit dealers to eliminate the troublesome features of handling and financing second-hand cars.

C. H. Peterman is president of the corporation; J. A. Wissell, vice-president, and H. J. Berning, secretary and treasurer.

A.A.A. Visits Harding, Approves Townsend Bill

WASHINGTON, May 17—Representatives of the American Automobile Association in convention here this week called upon President Harding to-day, and pointed out the need for better highways and expressed hearty approval of the proposed Townsend bill, which is now before the Senate. Later the delegates attended hearings of the Senate Committee on Post Office and Post Roads, which is gathering opinions as to the effectiveness of the Townsend bill in correcting abuses now existing in highway administration.

The delegates discussed automobile thievery, policing for the National highways, opposed the discriminatory taxes on automobiles, and discussed the gasoline price situation.

Senator Townsend and other legislators addressed the conference at a dinner given Monday at Hotel Washington.

Western Radiator Formed to Combine 2 Companies

CHICAGO, May 18—The Western Radiator Corp. has been organized to take over the Hooven Radiator Co. and the B. & W. Mfg. Co., both of this city. The purchase of these two companies gives the Western Radiator Corp. one of the most complete lines of radiators. Production will continue in the fine Western Avenue plant to which the B. & W. equipment is being moved. Additional equipment has been provided for increased production of numerous types of radiators. The factory has a capacity of fully 2000 radiators a day.

New Jersey to Campaign for Fair Legislation

NEWARK, May 16—The New Jersey Automotive Trade Association, at its annual meeting in the Robert Treat Hotel here this afternoon, decided to carry its fight for better highways direct to the people and make it a dominant issue in the election of State legislators next fall.

The dealers are aroused by a condition which practically amounts to the stoppage of all highway development in 1922. The last Legislature, after increasing automobile fees and providing for a larger program of highway development than was asked for by the automotive interests through the State Highway Commission, failed to provide a proposed bond issue which would make highway improvement possible.

After hearing a report of George Paddock, one of the State Highway Commissioners, showing the deplorable condition of the highway program the association was unanimous in a resolution pledging itself to use every effort possible to acquaint the people of the State with the situation so that there may be no further delay than already occasioned. It was further resolved that the fight be carried into every county and that the citizens be asked to send to the Legislature only men favorably disposed toward good highways and who are familiar with highway problems.

CARPENTER ATLAS PRESIDENT

LANSING, MICH., May 14—Samuel H. Carpenter, former secretary of the Atlas Drop Forge Co., has been made president and general manager and will be succeeded as secretary by J. P. Hopkins, who also will retain the position of vice-president. Earl W. Goodnow was elected to the board and will become assistant secretary.

The changes were announced at a meeting of the board of directors Tuesday at which the favorable financial condition of the company was drawn to the attention of the stockholders.

Calendar

SHOWS

Sept. 28 - Oct. 8 — New York, Electrical Exposition, 71st Regt. Armory, Electric Equipment, Machinery and Vehicles.

Nov. 27-Dec. 3—New York, Automobile Salon, Hotel Commodore.

January — Chicago, Automobile Salon, Hotel Drake.

FOREIGN SHOWS

May 28, 1921 — Czecho-Slovak International Automobile Exposition of Cars, Trucks, Tractors, Motorcycles and Equipment. Prague.

May 28-June 8 — International Automobile Exhibition, Basle, Switzerland.

June, 1921—Reykjavik, Iceland, Agricultural Exhibition—Agricultural Machinery—Icelander Agricultural Society, Reykjavik, Iceland.

September—Buenos Aires, Argentina, Passenger Cars and Equipment. La Pabellon de las Rosas. Automovil Club Argentino.

September—Buenos Aires, Argentina, Cars, Trucks, Tractors, Farm Lighting Plants and Power Farming Machinery. Palermo Park; Sociedad Rural Argentina.

September—Luxemburg, Luxemburg, Agricultural Sample Exhibition.

Oct. 5-16—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

Nov. 4-12 — London, British Motor Show, Society Motor Mfrs. and Traders.

May, 1922—Quito, Ecuador, Agricultural Exposition, celebrating Centenary of Ecuador. Automotive Section.

CONVENTIONS

May 23-26 — Chicago, A.S.M.E. Spring Meeting, Congress Hotel.

May 24-28—West Baden, Ind., Summer Meeting Society of Automotive Engineers, West Baden Springs Hotel.

July 4-9 — Mackinac Island, Mich., Summer Meeting Automobile Equipment Association.

Oct. 12-14, 1921 — Chicago, Twenty-eighth Annual Convention National Implement & Vehicle A'ssn.

RACES

May 30 — Indianapolis, International Sweepstakes.

June 3-5 — Reno, Nev., First Annual Nevada Highway Road Race.

June 18—Uniontown, Pa., Speedway Events.

July 25—Grand Prix, Le Mans.

Labor Day—Uniontown, Pa., Autumn Classic.

INDUSTRY ASKS SENATE TO REPEAL "STIGMA TAX"

(*Continued from page* 1085)

that the industry should be relieved of the sales tax on cars, trucks and repair parts.

Replying to a statement of Senator Simmons of South Carolina, ranking Democratic member of the committee, that the Government did not build the road beds for the rail carriers as it did for the automotive industry, Graham pointed out that nobody ever heard of steamships digging their own channels or building their own harbors, but that the Government paid for it. This illustration was considered very apt. He said that the industry pays enough for the maintenance of all vehicles. Graham placed the automobile industry in favor of a sales tax, provided it is extended to all industries and as such would be equitable. Objection was made as to confining it to the automotive industry because it would be highly discriminatory.

Hanch Outlines Appeal

C. C. Hanch, chairman of the National Automobile Chamber of Commerce Taxation Committee, opened the argument for the industry. He outlined the recommendations of the organization, emphasizing the need for economy in Governmental expenditures. His suggestion that Federal expenditures be held to $2,000,000,000 annually was well received. Senator Penrose, chairman of the committee, inquired of Senator Smoot, ranking Republican member of the Senate Appropriations Committee, whether this was possible under existing conditions. Senator Smoot answered that they could not possibly reduce expenditures to $2,000,000,000 and take care of the proposed soldiers' bonus. Mr. Hanch found many sympathizers on the committee when he suggested that "it is time for at least a brief naval and military vacation."

The committee questioned Mr. Hanch closely as to the effect of the excess-profits tax. His assertion that there was a vast preponderance of public opinion for the repeal was questioned by Senator McCumber, who contended that the farmers did not want it repealed. Responding to a question of Senator Simmons, Hanch insisted that the excess-profit tax was a consumption tax in the last analysis.

Senator Penrose wanted to know of the discriminatory effect of such tax, as had been alleged by the automotive industry. Hanch said it discriminated against conservatively financed institutions and favored extravagantly managed concerns, put a limit on initiative and was extremely uncertain of return. He furthermore insisted that it was unfair in principle, as was true of the excise tax.

Hanch emphasized the need for lessening the tax burden on industry, particularly during the reconstruction period. He expressed the opinion that no additional burdens would be required before 1923, provided the Government was prudently conducted and a tight rein kept on expenditures. He indorsed the sales tax only in the event that additional revenue is needed and is placed on all industry.

Hearings to Continue

Hearings on the Internal Revenue revision will be continued for several weeks in order that the committee may ascertain the views of the country on this problem which vitally affects all.

The House Committee on Ways and Means undoubtedly will take up this matter after the tariff measure is reported, probably by May 26.

"A very strong impression was made upon the members of the committee," said Alfred Reeves, general manager of the National Automobile Chamber of Commerce, after the hearing to-day. "We were delighted with the reception accorded us. The committee was a hundred per cent more friendly than ever before, and seemed keenly alive to the problems confronting the industry. Much interest was shown on the part of the committee by its questions as to our attitude on current tax problems, and we were able to give convincing replies. Quoting President Harding carried much weight."

Presenting the industry's views on highway legislation before the Senate Post office committee, Graham said:

"National development and the need for economy demand the formation of a highway policy under a Federal Commission.

"The economic barrier now confronting us is the lack of adequate highways. There is urgent need to build these highways as quickly as possible.

"Highways should be planned with consideration of their relationship to railway and waterway communication. The highway question concerns agriculture, commerce, the military and the social needs of the nation.

"Highway policy, therefore," Graham continued, "should be unified under a Federal Highway Commission directly responsible to the chief executive, as is now the policy in State road administration.

"Economy will be served by such a measure as roads will be built with regard to all the needs of the nation. It will be possible to pay higher salaries than can now be done under the bureau system. Millions of dollars are to be expended on roads, and it is the highest economy to secure the ablest brains in the country for this administration."

CORRECTION

DETROIT, May 16—In the story on production in the Detroit district printed in AUTOMOTIVE INDUSTRIES last week the statement was made that "an interesting fact in connection with the Reo business is that its foreign trade has fallen to approximately half its normal total." This reference should have been to farmer trade instead of export business.

AUTOMOTIVE INDUSTRIES
The AUTOMOBILE

VOL. XLIV. NEW YORK—THURSDAY, MAY 26, 1921 No. 21

S. A. E. SUMMER MEETING

Education Dominant Thought at S.A.E. Summer Meeting

President Beecroft points way to attainment of results. Discusses foreign trade. Intensive research by S. A. E. not to conflict with competitive research. Hot weather greets convention visitors on arrival.

WEST BADEN, IND., May 24.

THE Society of Automotive Engineers is holding the hottest meeting in its history. Although accurate temperature figures are not available, each of the six hundred persons registered are ready to testify that this is a real summer resort and that summer has arrived in full force. Most of the visitors, however, had some taste of the hot weather before leaving home and so no one is inclined to blame this section of Indiana for the exceedingly warm reception which has been accorded. Everybody is having a good time in spite of the high temperatures.

The attendance is surprisingly good; much better than was anticipated early in the season. Six hundred arrivals have already been registered, while reservations have reached 650. Many arrivals are yet unregistered, so that the total attendance will probably be about 700. The attendance last year was 757, which was the largest for a summer meeting in the history of the society.

Both sessions held to-day were well attended. A surprisingly large number sat through the rather extended meeting of the standards committee in spite of the heat. The hall was also well filled to-night when President Beecroft delivered his address. His remarks centered about the subject of educational work and were listened to with close attention. He discussed especially the relation of the engineer to foreign trade and defined the various kinds of research work in general, together with the function of the research work to be carried on by the Society. President Beecroft's address was as follows:

It is a welcome opportunity to have the privilege and the honor to address you as your president because of what our society has accomplished in its brief history of 16 years, and also because of the character of the times through which we are passing, and the problems lying ahead with which we must cope. We have passed milestones on the automotive highway, but the future is not so clearly defined as we had hoped a few years ago it would have been, and within 12 months we have been brought face to face almost brutally with situations that have been anticipated by few, if any, in our industry. Our greatest concern is with the immediate future.

Within the last 12 months we have seen waves of industrial depression follow one another in long successive undulations, beginning at the Atlantic and ending at the Pacific. We have not only watched these waves traverse the breadth of our land but have seen them pursue their undulatory course across the Amer-

icas to our south, across Australia, Africa, Asia and devastated Europe, until we could not locate a single center on the earth's surface that seemed immune from the depression that we are still in the midst of.

We are not yet through liquidation, and are barely on the threshold of the adjustment period that lies ahead. These are days when courage is needed; when the fibre of which men are made is under the supreme test and when integrity and self-reliance are essential attributes of success.

This situation has suggested the subject of these remarks, namely, education, a more general consideration of fundamentals, a greater probing of one's self, and the development of greater self-reliance. In no field of human endeavor are these qualities more essential than in engineering, and this is specially true in a department of engineering such as transportation, with which we are connected and which is so inter-woven with all of the other industries of the world.

In transportation we must play our rôle and it must be a just and equitable one. We must give to the railroads what they can best do; we must give to the motor truck that which it can transport more economically than other means; to the commercial airplane should go that which can be best transported by it. There must be no inefficient wasting of the work by any form of transportation attempting to take onto itself that which can be more economically done by another medium of transportation. Corporational selfishness may exhibit itself and for a short time win, but in the end the economical will triumph, and in transportation, the straight line, as representing the greatest efficiency, will win. Heretofore the different kinds of transportation were warring more or less among themselves, vainly trying for the victor's share of the spoils. But a change of attitude has been exhibiting itself recently and now railroads are admitting the right of the motor truck in certain divisions of the transportation world, and are ready to leave those fields to it. Let the law be, render unto Cæsar that which is Cæsar's and to God that which is God's.

If the engineer is to maintain the status of his profession and pursue the ideal of seeking after the truth, then the pursuit of education must be an ever present and primary consideration. He must breathe the spirit expressed in the words of Ulysses: "To follow knowledge like a sinking star beyond the utmost bound of human thought . . . to sail beyond the sunset, and the baths of western stars until I die . . . to strive, to seek, to find, and not to yield."

For the first time in our industry since we shed our swaddling garments we are measuring ourselves with the other automotive manufacturing nations of the world. Before the war we were not an exporting nation, as our factory expansion which gave us the production we have to-day was developed during the early years of the war.

Previous to 1914 our foreign trade was a diversion; to-day it is a necessity. We find ourselves with factories of greatly expanded capacity, greater capacity than our domestic demands can absorb, and we are faced with the alternative of remaining in and increasing our position in the markets of the world or reducing output and depriving ourselves of the lower production costs we attained by virtue of volume production. For six years we have been in the markets of the world in a more or less representative way, but, lest we forget, may it be recalled that the world markets sought our wares and the world's buyers knocked on our doors; our task was easy—we opened the doors, took the remittances and delivered the merchandise.

Easy come, easy go, is an old proverb, yet still applicable and we might also further fortify ourselves by borrowing from divine writ words that can be applied to our foreign trade situation—namely, "Wherefore let him who thinketh he standeth take heed lest he fall."

Perhaps to some engineers foreign trade may seem far afield, but only last week the president of one of our greatest railroad systems in his testimony before the Interstate Commerce Commission attributed the present decline in railroad traffic to the falling off of our foreign trade, falling off $657,000,000 in three months of 1920 as compared with 1919. Not only has foreign trade affected our railroad systems but it is affecting all industries, and whatever factors affect the industries with which he is connected should properly be a matter of concern to the engineer.

Foreign trade, while directly a merchandising activity, has a very direct connection with engineering and its future will be to no small extent dependent on the knowledge the engineer has of the conditions and the characters of the people in the countries in which his product must perform. Some four years ago, when our expert sales departments ruled that a magneto was not necessary equipment because of our developed battery ignition systems, it was soon learned that conditions in many lands demanded the magneto, and, despite rulings, those companies that disregarded rulings and fitted the magneto were well repaid for their consideration. Others, who for a time resisted, were soon converted to the necessity of the magneto. In the end it was an engineering question, and, while from a merchandising viewpoint the dropping of the magneto seemed desirable in that it facilitated the production, yet in long-distance view, which should be the engineering view, it proved necessary. It is because of many situations of this character that engineering must be more intimately associated with such factory activities as merchandising and maintenance as well as with design and production.

The factory engineer becomes immediately a direct party to foreign trade. When sales in certain lands are decelerated, due to gasoline selling at $1 per gallon, or in another country where the horsepower tax is $5 per year per horsepower, we get a close-up realization of how interwoven engineering is with merchandising and how only the engineer thoroughly familiar with the fields in which his product goes can serve his company best. The engineer has not sufficiently weighed the factors involved in domestic trade, not to mention foreign trade.

It was not necessary until a year ago, as we had no world competition, but to-day, with European nations entering the field and with some of them actively in it for a year, it is necessary, if we are to retain our position, to give early consideration to these and other related questions.

To draw a parallel from our domestic field, two of our large farm tractor manufacturers have within the last thirty days concluded that the high cost of fuel in comparison with animal power has been one of the deterrents to the sale of farm tractors this year. If this becomes a considerable factor at home, where fuel is cheap and the machine is marketed at low cost, as compared with prices at which it must be sold in foreign fields, how much more a consideration does it become with $1 per gallon fuel and machine prices nearly doubled, due to freight, insurance, customs and shipping charges?

Only one year ago we found serious engineering de-

fects in certain cars in our own country, due to physical characteristics on our own Pacific Coast, and yet the engineer was ignorant of the facts and, still worse, obstinate in his conviction that he was right. It was finally the sales end that converted the engineer, whereas it is the duty of the engineer to be a guide to the sales and correct them where necessary. The engineering mind must give consideration to those factors that directly affect his company.

As engineers, be constantly remindful of the fact that your task is far from completion, and, while in the last thirty years, scarcely a generation, we have seen a measure of progress scarcely comprehended to-day, yet the goal lies far beyond the distant hills. Education is the greatest need of the hour in present-day engineering, and in this we may gain hope and inspiration in pursuing education along its devious paths from Lessing, the German philosopher, who in his "Education of the Human Race," speaking on the broad subject of evolution and the devious paths it pursues, which in places can scarcely be followed, says:

"Go thine inscrutable way, Eternal Providence, only let me not despair in Thee because of this inscrutableness. Let me not despair in Thee even if Thy steps appear to be going back. Is it not true that the shortest line is always straight?"

Education should only begin when college doors close behind us. The man does not truly live whoever concludes that his education is completed. "Education gives to man nothing he might educe for himself. It gives him that which he might educe for himself only easier and quicker. This in the same way that revelation gives nothing to the human species which the human reason left to itself might not attain, only it has given and still gives the importance of these things earlier."

The extension of knowledge and securing it quicker and easier is one of the functions of our society that your council has given consideration to since the first of the year and which was under consideration last year. Under the term research as related to our society, the dominant thought is securing of certain knowledge earlier and with less expenditure of effort and with greater conservation of the talent available for such work.

Your council has seen fit, after deliberate and mature consideration, to actively push the creation of a research committee that will take its place in the society activities along with standardization work. It is impossible to see what development lies ahead and what expenditures this department may make for the next few years, but in magnitude the research organization should exceed that of standardization and the growth of the department is only dependent on the enthusiastic support that is given by the membership.

Let us briefly analyze what research is, as contemplated, and what it would mean to our society and the members:

First, there has been no thought of creating a special research laboratory for the S. A. E. in which to carry on experiments necessary in any research, but rather that existing laboratories in the industry and outside of it be utilized for such work. The finances of the society would not permit of creating a special laboratory, and the feasibility of such would be gravely questioned at this time. There are in Government bureaus, such as the Bureau of Standards and the Bureau of Mines, and in our college laboratories and in our industrial laboratories ample equipment for all necessary research, and it would be wasteful to neglect the intelligent use of these facilities.

Second, there has been no thought in the research program as considered to encroach on what might be described as the secret developments of any corporation. There is nothing communistic or that flavors of engineering socialism in the contemplated program. The research program contemplates nothing more than has been considered as beneficial co-operation in associations of manufacturers. We have for years, even for centuries, considered these industrial associations, formerly known as guides for the efficient promotion of trade, not only desirable but essential. We are to-day accomplishing through them results not considered within the vale of possibility a few years ago.

There is nothing in the research planned that usurps the programs of the engineer to-day. There is no thought of extracting the scientific discoveries of one company and distributing them broadcast to the remainder of the industry. Rather research, as planned, is to do the things that thus far have been left undone. It is to obtain certain knowledge not only easier but quicker and to be more certain of its accuracy.

The term research will admit of certain analysis and, for our present convenience, we may consider it under three heads or classes:

1. First there is what might be designated explorational research, conducted in different fields, which is a purely scientific research largely conducted by individual scientists with the thought of extending the boundaries of human knowledge. This research is akin to an explorer starting on a mission of discovery in an unknown field, a case in point being that of the Scandinavian astronomist who has led a life of study in his observation stations within the Arctic Circle, where for twenty years he has studied the Aurora Borealis and as a result has established certain scientific relationships previously unknown to science and by virtue of which new scientific areas, so to speak, have been brought into the field for intensive study by the scientific and engineering world. With us this research program has little to do. It has not been considered as one of our major activities. It must be left to the physicist, the chemist, the mathematician and the general scientist.

2. Secondly, and related to explorational research, is what might be designated intensive research in the fields brought within the ken of engineering by explorational work. This intensive research field is the one that our program has to do with and in which our interest is greatest. It is in this field of intensive research where economy in effort is most needed and where the measure of work for an end accomplished is greatest. This intensive research is a job that involves co-operation and organization, and the talent used can rarely be used in explorational research.

An example of the research activity in this field might be work relating to fatigue in metals. Such work would involve an almost endless number of experiments and tests extending over long periods of time and over a wide range of materials and under varying conditions. Some of our universities have been conducting searches of this character in which tests have been carried on for over a year and are still far from completion.

These experiments in themselves do not give the answer to fatigue, but the findings must be interpreted, and from these interpretations deductions made so that it may be possible to predict the fatigue resistance of

metals. Intensive researches of this and similar character have and are in progress, and are supported by large industrial corporations who have their own research laboratories and who recognize the magnitude of the work and the urgent necessity of it by their liberal support.

3. The third kind of research is industrial or development research, which for convenience may be designated competitive research among manufacturers in the same field of industry, and is a research which our program takes no part in. Competitive or development research has largely to do with developing a design of a part or completed unit or entire vehicle for manufacture or patent protection. This is the research that many corporations are more directly concerned with and which their laboratories are largely engaged upon. This is the research generally carried on behind locked doors carrying the sign "positively no admission." This is the research which provides the manufacturing secrets of a corporation. Our contemplated program leaves such research where it is to-day, solely with the manufacturer where it rightly belongs. Our program does not even hint at unlocking the door or removing the sign. Competitive or development research is a company activity and must remain such.

Careful discrimination between this competitive or development research and intensive and explorational research must be constantly kept in mind. Research of the intensive character will tend to increase possibilities for competitive and development research rather than restrict them.

Considering the influence of turbulence in connection with the internal combustion engine, the knowledge of turbulence elevates the standard of practice of the entire industry to a higher and wider level on which each corporation interested has greater possibilities for individual development, patent protection, etc. It is only by a recognition of this that we will progress in knowledge as the demands of the day require.

May we interpolate, "research gives to man nothing he might not educe for himself, but it gives it to him easier and quicker." So with intensive research; the cost is so great and the time needed so long that only by co-operation and organization in the long chain of tests can we secure the knowledge quicker, easier, cheaper, and are sooner able to incorporate the results in industry. Do not forget, art is long and time is fleeting.

One great need to-day is the training of men competent to carry out the intensive research, needs not alone of our colleges but of our industries. Our colleges are not graduating enough men of research caliber to care for the needs unless co-operation and organization are used. We must conserve the human material we have available. No persons are more conscious of this shortage of research personnel than our college heads, and no one regrets this more than they do. Too frequently the curriculum are not conducive to such training.

Up to the last few years there has been little thought of co-operation for conservation in college research, and still less thought of co-operation in intensive research in industrial plants. There is to-day not only a lack of appreciation of research by the engineers but by company executives, and, just as our standardization program met with opposition at its inception and still does in some quarters, so we may anticipate opposition in research until it is more adequately understood.

Research is not going to deprive any engineer of his present work, rather it is going to enable him to obtain results which otherwise might not be possible. It is going to provide him with an arsenal well stocked with knowledge that will serve him and speed his efforts to better work.

Our research committee has had one specific object in mind; namely, securing as the director of this work a man competent not only to carry on intensive research work but to be capable of the more difficult task; namely, to correctly interpret the results obtained from such. There is a lack of uniformity of interpretation of results obtained and a consequent failure to reach conclusions and make correct deductions. In some intensive researches conducted by one engineer certain factors are neglected in experiments, so that comparison of results of experimentation covering the same field by other groups of engineers cannot be made. The measure of result that should have been achieved for the effort expended is not achieved. The money has been expended. The useful time has been consumed; the human energy has been consumed, but results are not what they should have been. A competent director should, with reasonable co-operation, be able to eliminate such losses.

Had we a surplus of human research talent our program for intensive research would scarcely be necessary, but with a shortage of available men the need for such co-operative work becomes imperative. In considering our research problem we suggest that the word research be divested of early associations and your conception of it be revised and that it be weighed in the light of the work to be done, the end to be accomplished and the tools and personnel available, keeping in mind the differences between intensive and competitive research. Do not forget that the confines of competitive and development research are not to be invaded or molested by our work, but that the field for such is to be broadened and lengthened by the intensive research program contemplated.

No time could be more appropriate than the present for the commencement of such work. In times of prosperity, when a company wishes a result along a certain research line, the answer is wanted almost immediately. Such is not possible. By beginning now the program will develop with a readjustment of the industry, and some progress will be made by the time urgent demands are coming in.

There is no thought in a co-operative intensive research program such as outlined of discouraging similar researches by corporations equipped and manned for such or of interfering in such work; but as with similar researches in the electrical and other fields, those corporations privately equipped for such work have been liberal in contributing their aid and finances for co-operative research. Such work will have a very desirable influence by creating greater self-reliance on the part of the individual engineer which will be engendered by such work. Those institutions that have made greatest progress in such work tell us that the personnel has very largely to be trained to the work.

Colleges by virtue of their curricula do not make research engineers. Individual training is necessary. Self-reliance is essential. Ability to proceed step by step from the known to the unknown is essential. The French philosopher, Rene Descartes, in the sixteenth century gave us a good example of what can be accomplished where self-reliance is developed. In his "Discourse on Method," in which Descartes laid the foundation work for modern thought and made possible the whole modern philosophic development, he says:

"Men should gather the greatest satisfaction from progress made in the search after truth. In the same

way I thought that the sciences contained in books composed as they are of the opinions of many different individuals massed together are further removed from truth than the simple inferences which a man of good sense, using his natural and unprejudiced judgment, draws respecting the matters of his experience. . . . The long chain of simple and easy reasonings by which geometers are accustomed to reach the conclusions of their most difficult demonstrations has led me to imagine that all things to the knowledge of which man is competent are mutually connected in the same way, and that there is nothing so far removed from us as to be beyond our reach, or so hidden that we cannot discover it, provided only we abstain from accepting the false for the true and always preserve in our own thoughts the order necessary for the deduction of one truth from another."

To-day, as always, the greatest problem in engineering is the engineer. Man dominates here as in all other spheres and only in proportion as the man, tagged as he may be with the title of engineer, etc., plays his part and considers the attainment of knowledge as the chief end in life, will our industry develop and will we reach that stature and be capable of measuring ourselves successfully with the nations of the world as we should.

We have been parties of an industry whose lot has been an easy one. As an industry we have grown by leaps and bounds. Our progress has been comparable to that of an army in the field that has made great gains of territory without adequately consolidating its position as it progressed and suddenly finds itself in an unexpected situation. We have not at all times taken accurate measure of our progress nor taken a sufficiently long-distance survey of the future. We are now at a time when looking ahead is more necessary than it has been heretofore. We require better qualifications to cope with the situation. For the first time we are in a world's competitive market; a market in which merit counts, and no effort must be neglected, no stone left unturned to fit us in the highest stage of perfection to meet the tasks that lie ahead.

The report of the treasurer showed the society to be in excellent financial condition, the net assets being over $130,000. This is about the same as last year, despite the heavy depression period through which we have passed.

C. F. Scott, chairman of the Meetings Committee, reviewed the last few meetings in his report and stated that seven general technical sessions have been held. Among the future meetings which have been arranged are several special sessions, including a joint gathering of the S.A.E. and A.S.M.E. at the Aberdeen, Md., Proving Grounds. This meeting will be held some time in October and has been arranged at the invitation of the Ordnance Department.

The annual motor boat meeting will take place as usual in New York City during the motor boat show. The date of the annual winter meeting has not yet been fixed. It will not be determined until the date of the New York show has been announced. It has been suggested that the winter dinner and carnival be combined into one affair this year. The Meetings Committee is considering the holding of extension meetings in industrial centers where no sections are now located.

The Sections Committee reports that there are now eleven sections in the society. The new additions since last year are Boston, with a membership of 57; Dayton, with 60, and Washington, with 25. The members in California have had two luncheon meetings, but a section in that State is not being planned at this time. The number of section members for 1921 is 1209 as compared with 1085 a year ago. The Society now has 5468 members. A year ago there were 5231. The membership committee reports a steady growth in all grades of membership. The full members now total 2790, an increase of 84 for the year.

Three members of the Nominating Committee were elected at the meeting to-night. Because this committee is to complete its work during the meeting held here, it was required that all the nominees be present. Those elected were: George P. Dorris of St. Louis, Elmer A. Sperry of New York, and R. E. Northway of Boston.

The other members of the Nominating Committee are elected and reported by the various sections. They are: Boston, L. W. Rosenthal; Buffalo, H. R. Corse; Cleveland, A. E. Jackman; Dayton, T. A. Midgley; Detroit, Russell Huff; Indiana, W. G. Wall; Metropolitan, H. W. Slauson; Midwest, Force Bain; Minneapolis, A. W. Scarritt; Pennsylvania, F. W. Germane; Washington, H. C. Dickinson.

The Standards Committee held one of its most successful meetings. It passed practically all of the standards as printed in AUTOMOTIVE INDUSTRIES of last week. The exceptions were that portion of the parts and fittings division which affects studs and the report on battery ratings for isolated plants. Both were referred back to their respective committees for further consideration.

Hard Copper

EACH month numerous requests are received by the Bureau of Standards for information concerning the hardening or tempering of copper. As the information desired by all those writing to the Bureau appears to be about the same, it has seemed desirable to make a short statement on this subject.

There is nothing new or mysterious about hardened copper. It is not one of the lost arts; immense quantities are in commercial use and added uses for it are being found every day. There are two well-known methods of hardening copper, the first being by means of mechanical working, while the second is to alloy it with a certain amount of another metal and in some cases with more than one metal. As examples of the first kind of hardened copper, we may consider hard drawn copper wire and cold drawn tubing. The wire used for every-day trolley systems is a good example of one of these classes. Copper hardened by the second method is not usually referred to as copper but as brass and bronze. Many persons apparently ignorant of the fact that hardened copper is in use every day have so manipulated the melting of copper in their experiments that the resulting melt is impregnated with oxide. Cuprous oxide is soluble in molten copper and alloys with it in exactly the same sense as the metals mentioned above. Copper treated in this way is considerably harder than the pure metal but is unsuited for most commercial purposes.

The above information will come as a disappointment to the many thousand metallurgical sharps who have rediscovered the secret of the ancient Egyptians within the recollection of the present generation alone.

S. A. E. SUMMER MEETING

Cylinder Actions in Gas and Gasoline Engines

Condensed from a paper prepared for the Semi-annual S.A.E. Meeting by Sir Dugal Clerk, the eminent British authority on gas engines. Inflammation, turbulence, specific heat of gases and other items are discussed.

SIR DUGALD CLERK, in his paper prepared for the S.A.E. Summer Meeting, discusses various phases of the combustion in engine cylinders in the light of experimental results obtained by himself and others. Most of his experiments were made with coal gas, and while the numerical results are not exactly the same as would be obtained with gasoline, they throw much light on what may be expected in gasoline engines. The principal actions common to all internal combustion engines are described as follows:

During the suction stroke of the ordinary four-stroke internal-combustion engine, the charge of air and gas or air and gasoline vapor and spray flows through the valve opening at a velocity which usually exceeds 100 ft. per sec. or 68 m.p.h. It enters the cylinder and fills it with a mixture of the fresh charge and the exhaust gas remaining from the last power stroke, all in a state of violent agitation or eddying. This agitation dies down in time, but at the end of the compression stroke, just before ignition, there remains a considerable internal motion. In a gas engine of 9-in. cylinder diameter and 17-in. stroke tested by me I found the residual turbulence at that point sufficient to increase the velocity of the spread of the flame after ignition to three times that which occurs in a still mixture of the same composition. As this state depends on the piston speed, an increase of the piston speed causes an increase of the initial turbulence, and hence a more rapid spread of flame to meet the increased rate of piston movement. Without this automatic change of ignition rate the high-piston-speed gasoline engine would have been impossible.

During the suction stroke the mixed charge passes through the valve opening at the temperature of the atmosphere, in the case of the gas engine, but somewhat below it in the usual case of the gasoline engine, due to evaporation of the liquid fuel; and as the valves and piston-end and cylinder walls are hotter than the charge, heat flows into it, and whenever the charge is complete its temperature is raised in a gas engine to about 212 deg. Fahr., partly because of the heat-flow into the charge and partly because the cool charge is mixed with a certain proportion of hot exhaust-gases at beginning of suction stroke, whose temperature is about 930 deg. Fahr.

This mixture at the suction temperature of 212 deg. Fahr., when compressed in the engine mentioned which has a 5.5 compression-ratio, rises to about 680 deg. Fahr. at a pressure of about 120 lb. per sq. in. above atmosphere. On ignition the temperature rises to a maximum of 2912 deg. Fahr. in about 1/40 sec., and the maximum corresponding pressure becomes about 330 lb. per sq. in. above atmosphere at nearly 1/20 of the forward stroke. The speed of this engine is 200 r.p.m., so that one revolution takes 0.30 sec. and a single stroke 0.15 sec. Had turbulence been absent at the time of ignition it would have required nearly 0.1 sec. to complete the spread of the flame and the maximum temperature would not have been attained till half stroke forward.

The time of inflammation necessary for a gasoline engine running at 1200 r.p.m. is much shorter; at this speed it should not exceed 1/120 sec., and at higher speeds much greater rapidity is required to give reasonable efficiency. The late Dr. W. Watson gave 1/300 sec. as the time in a small gasoline engine tested by him. Assuming the flame to travel 4 in. to fill the small cylinder, then its velocity must be 100 ft. per sec.

With gasoline engines operating at 1600 r.p.m., with overhead valves opening directly into the cylinder which was 7.25 in. in diameter with an 8.50-in. stroke, Sir Dugald obtained an indicated thermal efficiency of 33 per cent, and this value is about 0.7 of the air standard and about 88 per cent of the actual working-fluid standard. Mr. Ricardo has designed and built a special single-cylinder gasoline engine arranged so as to permit of altering the compression-ratio while the engine is running. He has published (Table 1) the maximum indicated thermal efficiency obtained at values of 1/4, 1/5 and 1/7 respectively for $1/r$. To enable this wide compression range to be attained he used benzol. Mr. Ricardo followed Sir Dugald in giving an approximate formula for the actual working-fluid efficiency at different compression. The latter proposed the use of a value of 1.285 for γ for the particular fluid of the gas engine; for the products of combustion of benzol and gasoline Mr. Ricardo uses 1.295.

TABLE 1—VARYING COMPRESSION-RATIO EXPERIMENTS USING BENZOL

Compression-Ratio	Maximum Indicated Thermal Efficiency Calculated $E = 1 - (1/r)^{0.295}$	Maximum Indicated Thermal Efficiency Observed	Ratio of Observed to Calculated Thermal Efficiency	Air-Cycle Efficiency	Ratio of Observed Thermal Efficiency to Air-Cycle Efficiency
1/4	0.337	0.277	0.82	0.425	0.650
1/5	0.380	0.316	0.83	0.475	0.665
1/7	0.440	0.372	0.85	0.540	0.685

The change from ¼ to 1/7 compression-ratio raises the indicated thermal efficiency from 27.7 to 37.2 per cent; that is, only 74.5 per cent of the fuel used at the low compression is required to produce the same power at the higher, and the ratio between no heat loss and practice rises from 82 to 85 per cent. The mechanical efficiency also rises, so that the saving is well worth making. The air-cycle ratio varies from 0.650 to 0.685, practically 0.7, the same as with the gas engine.

Sir Dugald referred to the subject of detonation and said that it was a very old trouble, as he experienced it with the first (two-stroke) engines he built in a very pronounced form. In later engines he overcame the trouble

by using what he refers to as exhaust super-compression, that is, injecting cooled exhaust gases into the cylinder at the charging end of the stroke so as to raise the pressure of the charge to 3-5 lb. p. sq. in. above atmosphere before compression began. He expressed the opinion that trouble from knock in present day kerosene engines could be eliminated by using a mixture of exhaust gas from the engine with the air entering the cylinder.

Turbulence

Reference is also made to the subject of turbulence, and in this connection Sir Dugald claims to have discovered that the turbulence created by the high velocity of the air and gas in entering the cylinder, persists during the compression stroke of the gas or gasoline engine to a sufficient extent to affect profoundly the rate of inflammation of the compressed mixture. This investigation was made in 1911. Long before that time he was fully aware that (*a*) turbulence existed in the engine cylinder during the admission of the charge through the inlet valve and passage and (*b*) that if turbulence be produced in a mixture of gas and air the inflammation of the charge proceeds more rapidly.

The flame velocity in an engine varies with the suction velocity and also with the gaseous or liquid fuel employed. Thus in one large cylinder gas engine of 22-in. diameter and 34-in. stroke, running at 160 r.p.m., the explosion period with Mond gas, suction gas and coal gas was respectively 1/21, 1/24, and 1/38 sec., and the corresponding flame velocity 47, 54 and 85 ft. per sec. The inlet velocity was 160 ft. per sec. In a smaller gas engine the inlet velocity was 100 ft. per sec. and the flame velocity 37 ft. per sec. With the richest mixtures used in gas and gasoline engines the flame temperature rises as a maximum value to 3632 deg. Fahr., although one set of experiments made by Professors Dalby and Callendar reached 4352 deg. Fahr. In both gas and gasoline engines the rate of flame transmission with turbulence varies from 30 to 100 ft. per sec.

Sir Dugald says that in a book on The Gas Engine published in 1886 he developed the thermodynamics of the engine and deduced the equation for thermal efficiency in terms of compression ratio as follows:

$$\epsilon = 1 - (1/r)^{\Upsilon-1}$$

where $1/r$ is the compression ratio. This is now often referred to as the air standard efficiency. It has the following values for different compression ratios: ½ — 0.246; ⅓ — 0.360; ¼ — 0.430; 1/5 — 0.480; 1/6 — 0.510; 1/7 — 0.550; 1/10 — 0.610; 1/20 — 0.700; 1/100 — 0.850. A Committee of the Institution on Efficiency of Internal Combustion Engines adopted this standard. It made tests on three engines, of 5.5, 9 and 14 in. bore respectively, all using a compression ratio of 5.5, and by dividing the indicated thermal efficiency by the air standard efficiency the result was 0.61 for the 5.5 in. bore engine, 0.65 for the 9-in. bore and 0.69 for the 14-in. bore engine. As a result of many tests it can be accepted that in practice, if we calculate the maximum indicated thermal efficiency from the corresponding ratio of the air standard, 0.6 can be taken as the minimum and 0.7 as the maximum.

It was known in 1905 that the specific heats of the products of combustion are higher than that of air and that they increase with rise in temperature, but the specific heat values were very uncertain. Accordingly Sir Dugald set to work with the largest engine available to the Committee on Efficiency of Internal Combustion Engines and determined the specific heat of the flame in the combustion chamber by a new method depending on alternate compression and expansion of the flame within the cylinder. As a result he reached the conclusion that the engine converted into indicated work 88 per cent of the heat which it possibly could have converted into work, considering the properties of the working fluid. These tests were made on a slow speed large bore engine, but recent experiments made by Mr. Ricardo have shown that equally good results can be obtained with gasoline engines.

In 1911 Sir Dugald observed that the rate of explosion rise in an engine varied with the rate of revolution, and he ascribed this to the turbulence or eddying caused by the rush of gas into the cylinder during the suction stroke, which persisted during the compression stroke. In most gas and gasoline engines the mean velocity of charge-flow through the inlet-valve is at the rate of 100 ft. per sec., and flame carried at this rate would completely fill the combustion space of this engine in about 1/130 sec., as the distance from each igniter to the extreme wall-limit is about 9 in. The actual time taken for normal complete inflammation was respectively 1/27 and 1/30 sec., so that the rate of normal flame-propagation with turbulence was about $100 \div 4.5 = 22.25$ ft. per sec., while the rate with trapped ignition and turbulence nearly-died-down was about 8.9 ft. per sec. From this it appears that the effect of suction turbulence is to increase the rate of inflammation about 13 ft. per sec. in this particular engine running at 180 r.p.m. The rate of inflammation in Clerk's closed-vessel experiments with a similar mixture was about 4 ft. per sec., and in Bairstow and Alexander's corresponding experiments 2.5 ft. p.s. In a large vessel having a capacity of 6.2 cu. ft. with a similar mixture, Hopkinson found the rate of inflammation 5 ft. p. s. The velocity of inflammation in an actual engine is thus from 4 to 5 times that found in a closed vessel by Clerk and Hopkinson, and 9 times that found by Bairstow and Alexander. Clerk's experiments would suggest a residual turbulence effect in this engine at the moment of about 20 ft. p. s.

The late Professor Hopkinson experimented on turbulence at the same time, but he operated in a closed vessel and produced his turbulence by the rotation of a fan within the mixture. He used a cylindrical vessel 12 in. in diameter by 12 in. long, with the fan mounted at the center. The experiments showed a great increase of the speed of inflammation consequent on the motion of the gas. With a mixture of 1 part of gas and 9 parts of air by volume, the time from ignition to maximum pressure with the gas at rest was about 0.13 sec.; with the fan running at 2000 r.p.m. it was reduced to 0.03 sec., and at 4500 r.p.m. to 0.02 sec.

Method of Measuring Specific Heat

To study the phenomenon of heat loss and the variation of specific heat, Sir Dugald in 1904 devised a new method of experimentation already referred to. By it the actual working fluid behind the piston could be made to give information on these points during the process of explosion. A 14 x 22 in. single cylinder engine was used, and the exhaust and inlet valve levers were furnished with pins of extra length, so that the rollers on these pins could be moved into and out of the range of the cams.

A spring-and-trigger gear was arranged so that the rollers could be put out of range of the cams at any required instant. By this contrivance the engine could be run in its normal way in accordance with the Otto cycle at either light or heavy load, and any given explosion could be selected for the purpose of the experiment by operating the trigger at the proper moment. It was thus possible to run the engine at its normal speed under the usual propelling explosions, and to select at any given moment any particular charge, move the rollers out of the range of the cams immediately the charge entered, and so obtain an explosion and expansion stroke in the usual manner, with the usual charge. But both inlet and exhaust-valves were held closed and the charge was retained in the cylinder.

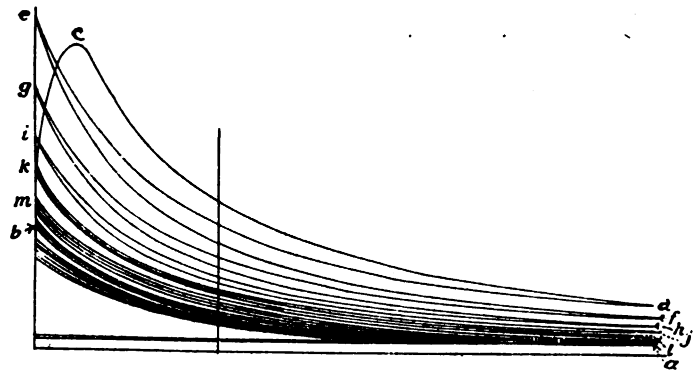

Fig. 1—Diagram of the explosion and alternate compression and expansion of hot gases in an internal-combustion engine cylinder.

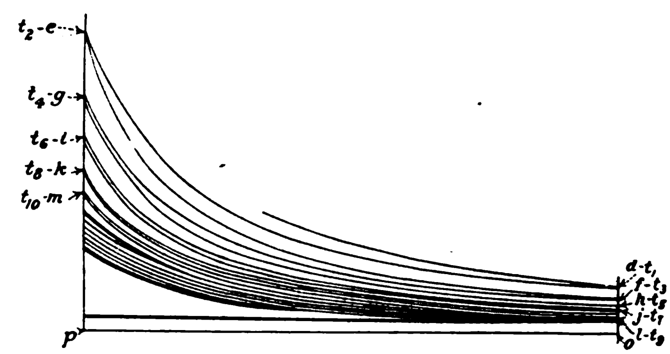

Fig. 2—A compression and expansion diagram with the explosion line omitted.

When the exhaust period was approached, the exhaust-valve remained shut, and accordingly the hot exhaust-gases were retained in the cylinder and compressed by the return stroke of the piston into the combustion space at the end of the cylinder. The energy of the flywheel was sufficient to keep up the rotations of the engine, with but little fall in speed during the short period of observation. The piston was thus caused to move to and fro, alternately compressing and expanding the hot gases which were contained in the cylinder.

An indicator-card taken from such an initial explosion and expansion and the subsequent series of compressions and expansions is given at Fig. 1; *a b* is the ordinary compression-line indicating the compression of the charge before explosion, *b c* is the usual explosion-line, and *c d* the usual expansion-line after explosion. At *d*, however, instead of the pressure falling to atmospheric by the opening of the exhaust-valve, as the exhaust-valve remains closed no escape of the hot products of combustion is possible, and accordingly the return of the piston produces the compression-line *d e*; the next outward movement of the piston produces the expansion-line *e f*, followed by the compression-line *f g*; expansion-line *g h*; compression-line *h i*; expansion-line *i j*; compression-line *j k*; expansion-line *k l*, and so on.

In Fig. 2 is shown the expansion and compression diagram without the explosion line. Referring to this diagram, the fall in temperature between *e* and *g* is not entirely due to cooling, which may be shown as follows: When the expansion *e f* takes place, the gases perform work on the piston equal to the area *e f o p*; when the compression *f g* takes place, the piston performs work on the gases equal to the area *f g p o*, so that more work has been performed by the gases on the piston than by the piston on the gases. Some work has therefore been done by the gases during the interval between points *e* and *g*. That is, part of the temperature difference t_2-t_4 is due to work done; it is not all due to heat lost through the cylinder walls. The difference between the two work areas is *e f g*.

If the specific heat of the gaseous mixture at the temperatures between t_2 and t_4 be known, then the temperature-fall due to the work-area *e f g* can be calculated, and when deducted from the total temperature-fall it gives the temperature-fall due to heat-flow through the cylinder walls. It is found that the specific-heat value need be only approximately known, as the temperature-fall equivalent of the work-area *e f g* is small in comparison with the total temperature-fall, and little error is introduced by a considerable error in the specific-heat value. This method enables a true temperature-fall curve to be drawn, showing the progressive fall of temperature incurred from revolution to revolution under the actual working conditions of the engine.

Proceeding in the manner described, Sir Dugald prepared cooling curves from the 14 x 22 in. engine under two conditions, viz. (*a*) without load, the cylinder kept cool and the engine running at 120 r.p.m.; (*b*) with full load, jacket at 160 deg. Fahr. and engine running at 160 r.p.m.

The cooling curves show the temperature fall due to heat loss, with mean temperature of the gases varying from 212 to 2732 deg. Fahr. and the exposure calculated to one second. Fig. 3 gives the temperature falls incurred per second for different mean temperatures, calculated in time. Curves *a a′* refer to no load operation at 120 r.p.m. with the cylinder kept cold by running water at 55 deg. Fahr. through the jacket. Curve *a* is for the complete stroke, while curve *a′* is for the first three-tenths of the stroke only. Curve *a* when prolonged to the zero of temperature fall cuts it at the temperature of 149 deg. Fahr. This

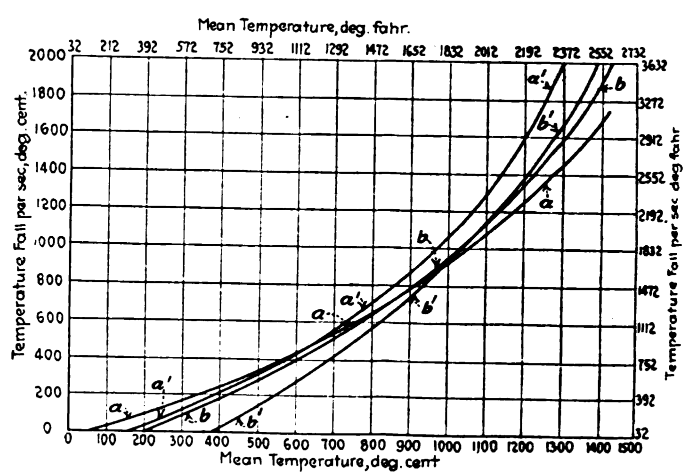

Fig. 3—Fall in temperature per second for different mean temperatures.

means that when the gases reach this temperature no further loss of heat to the cylinder wall takes place, and this therefore must be the mean temperature of the cylinder wall. This cylinder wall, of course, includes valve surfaces and piston head.

Curve *a′* when extended cuts the zero line at 329 deg. Fahr., which indicates that the mean temperature of the cylinder walls is much higher during the first three-tenths of the stroke than during the whole stroke. The curves *b b′* refer to full load operation at 160 r.p.m. with the jacket temperature at 176 deg. Fahr. As before, curve *b* is for the whole stroke and curve *b′* for the first three-tenths of the stroke. Curve *b* cuts the zero line at 374 deg. and curve *b′* at 752 deg. Fahr., indicating these to be the mean temperatures of the cylinder wall during the full stroke and the first three-tenths respectively.

From the curves of temperature fall given in Fig. 3 and specific-heat values of the gaseous contents of the cylinder, heat-losses can be calculated on the explosion-expansion line independently of any knowledge as to the completeness of combustion at any point, and for this purpose Sir Dugald determined the specific heat of the gases (Tables 2 and 3) in the following manner: If a gas be compressed without gain or loss of heat from volume V_0 to V_1, and the temperature rises from T_0 to T_1, the mean specific heat of the gas per unit volume at 0 deg. Cent. (32 deg. Fahr.) and a pressure of 760 mm. (29.92 in.) of mercury at constant volume between the two temperatures is

$$C_v = W \div [\Psi_0 (T_1 - T_0)]$$

where

C_v = the mean specific heat
W = the work done upon the gas
Ψ_0 = a constant depending upon the quantity of gas in the cylinder

TABLE 2 — APPARENT INSTANTANEOUS SPECIFIC HEATS IN FOOT-POUNDS PER CUBIC FOOT OF WORKING FLUID AT 32 DEG. FAHR. AND 29.92 IN.

Temperature, deg. Fahr.	Specific Heat at Constant Volume, ft-lb.
32	19.60
212	20.90
392	22.00
572	23.00
752	23.90
932	24.80
1,112	25.20
1,292	25.70
1,472	26.20
1,652	26.60
1,832	26.80
2,012	27.00
2,192	27.20
2,372	27.30
2,552	27.35
2,732	27.45

TABLE 3 — MEAN APPARENT SPECIFIC HEATS IN FOOT-POUNDS PER CUBIC FOOT OF WORKING FLUID AT 32 DEG. FAHR. AND 29.92 IN.

Temperature, deg. Fahr.	Specific Heat at Constant Volume, ft-lb.
32- 212	20.3
32- 392	20.9
32- 572	21.4
32- 752	21.9
32- 932	22.4
32-1,112	22.8
32-1,292	23.2
32-1,472	23.6
32-1,652	23.9
32-1,832	24.1
32-2,012	24.4
32-2,192	24.6
32-2,372	24.8
32-2,552	25.0
32-2,732	25.2

This is true of expansion as well as compression. The dynamical value of the rise or fall of 1 deg. Cent. (1.8 deg. Fahr.) for 1 cu. ft. of the gas will be given by the formula:

$$D_v = W \div [V (T_1 - T_0)]$$

where

W = the work done on or by the gas in foot-pounds
V = the volume in cubic feet
D_v = the dynamical value in foot-pounds

From cooling curves determined during the actual operation of the piston in the gas-engine cylinder in the manner described, and the dynamic value of the temperature-falls at high and low temperature in foot-pounds per standard cubic foot of working fluid, calculated from specific-heat values, balance-sheets of the engine have been prepared from indicator measurements only. No gas measurements or determinations of heat-flow to jacket-water are required. A heat balance sheet taken from the 50 hp. engine running at full load is given in Table 4.

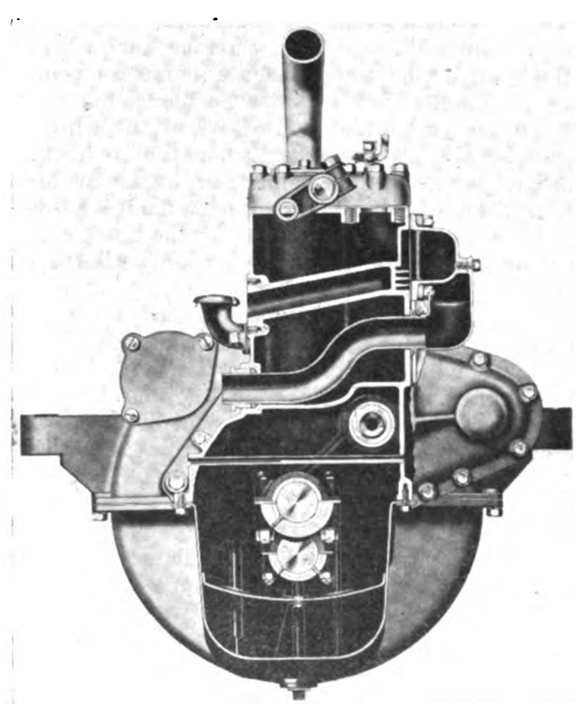
TABLE 4—HEAT BALANCE-SHEET

Card No.	22	
	Ft-lb.	Per cent
Heat-flow during Explosion and Expansion	12,480	15.4
Heat Contained in Gases at End of Expansion	39,800	49.0
Indicated Work	28,900	35.6
Total Heat	81,180 (104 B.t.u.)	100.0

If the combustion is nearly complete at the end of the stroke, the heat present found in this way should be equal to the evolved by the gas known to be present in the charge. The gas present in the charge is known to be approximately 0.183 cu. ft. at the working temperature of the measuring meter, and its lower calorific value was 574 B.t.u. per cu. ft. The heat of combustion of the gas is therefore $0.183 \times 574 = 105$ B.t.u. It is thus seen that the approximation is very close. The indicator has been able by the new method of application to account for the heat present in the charge.

Hot Air and Inlet Pipe on New Supreme Engine

THE accompanying photograph shows a sectional view of the new Model S-4 Supreme engine. In this engine the carbureter is located on the opposite side of the engine from the valves, and the arrangement of the hot air pipe from the exhaust manifold to the carbureter and of the inlet pipe from the carbureter to the manifold is rather neat. The inlet pipe is cast integral with the cylinder block. It extends across the cylinder block between the second and third cylinders and ends in the hot spot inlet manifold cast integral with the cylinder block. The hot air inlet tube is a bent pipe extending from the air heater secured to the under side of the exhaust manifold to the opposite side of the engine. Note the manner in which water-tight joints are made with the jacket walls. Another interesting feature is the control tube across the crankcase.



Arrangement of hot air tube and inlet pipe on Supreme S-4 engine

The Modern Motor Truck

THE construction and operation of all the leading tyes of gasoline and electric trucks are discussed in a detailed and practical manner by Victor W. Pagé in the 1921 edition of his volume entitled "The Modern Motor Truck." The book is designed for the use of truck owners, users and drivers and contains information of great value to the practical mechanic for use in his daily work. Pagé's work is too well known to readers in the industry to render necessary any detailed discussion here.

S. A. E. SUMMER MEETING

Flame Characteristics and Their Influence Upon Combustion

A paper which deserves study even if its application is not at first apparent. The analysis of factors controlling combustion and detonation and the means suggested for controlling these phenomena are considered.

By C. A. French*

THE present state of our knowledge does not permit of an exact scientific definition of flame, for the reason that it may be the result of either electrical, thermal or chemical action, or, perhaps, a combination of two, or all of them. Flame does not necessarily indicate combustion. The flames in the Moore tube, the Geissler tube or the mercury vapor lamp, do not arise from combustion; neither can their glow be attributed largely to thermal action. Solar protuberances, according to the common view, are gases whose glow is of purely thermal origin, but colorless gases in a tube cannot be made to glow by thermal action alone.

Combustion, either slow or fast, is not always accompanied by flame. Burning hydrogen and oxygen, if both are pure and dustless, make no visible flame even in the darkest room, according to the experiments of J. S. Stas. This is consistent with the fact that the line spectrum of hydrogen lies wholly within the ultra-violet. In the combustion of ethylene and chlorine the attendant radiation is below the pitch of visibility. In catalytic flameless combustion, which may begin with the hydrocarbon mixture and catalyst below zero fahr. and end 2000 to 3000 or more degrees above, there is no flame whatever, nor does the catalyst propagate flame even when surrounded by an excess of very rich combustible mixture. Surface combustion, which is entirely distinct from catalytic flameless combustion, may be regulated so as to show no flame, but that is on account of the very great luminosity of the white hot refractory surfaces back of the transparent blue flame. It will always cause a visible flame if an excess of mixture is supplied. The cause of transparent flames is doubtless largely electrical, while the cause of the opaque luminous red, yellow and white flames is probably almost entirely thermal.

A consideration of these facts will show the present impossibility of a strict definition. For the purpose of this paper, flames will be regarded as gases rendered temporarily visible by reason of chemical action; their physical rather than their chemical aspects will be discussed; and, unless otherwise indicated, it will be understood that only the flames of common gasoline and kerosene are referred to.

Many combustion phenomena can be explained only by the assumption that in normal blue flame the fuel burns from the molecule. In explosive combustion present-day gasoline and kerosene refuse to burn with an entirely blue flame under the conditions we use them. They burn with a very objectionable luminous sooty flame, which causes detonation and carbon deposits; while lighter fuels of the same general character burn in an inoffensive manner and give much higher thermal efficiencies. To gain a reasonably clear understanding of the requirements and characteristics of the different kinds of flames it is necessary to start with a study of atoms and molecules. Dr. Irving Langmuir says of atoms, "If a lump of ordinary matter the size of a baseball could be magnified to the size of the earth, the atoms in it then would have become about the size of baseballs." Atoms are believed to be composed of charges of positive and negative electricity. The positive electricity is concentrated into a very small particle called the nucleus, located at the center of the atom. The negative electricity exists in the form of electrons which arrange themselves in space around the nucleus. The electrons in different kinds of atoms are alike, but there are as many different kinds of nuclei as there are chemical elements. These differ from one another only in the amount of positive electricity they carry. For the simplest element, hydrogen, the nucleus has a unit positive-charge which is able to neutralize the charge of a single electron. Thus a hydrogen atom consists of the nucleus and a single electron. The next element, helium, has a nucleus with a double positive-charge, and the atom thus contains two electrons. Atoms of carbon have six and oxygen eight electrons. The electrons are not stationary but each revolves in its own orbit about a certain equilibrium position. It is thought that all atoms occupy about the same spaces.

As atoms are thought to be spherical, it is possible that molecules usually are of the same compact symmetrical shape; at least their behavior in combustion is best explained by this assumption. If we take any number of ½-in. balls less than 13, and arrange them in a symmetrical spherical form, it will be seen that none is entirely covered and cut off from contact with the outside. By taking the 13 balls it will be found that there is one ball in the center that is entirely surrounded. As we know that nature abhors a vacuum, we imagine that there is one atom in the exact center of any ordinary stable gaseous molecule. We find that by starting with one ball, or atom, in the center we can arrange 12 more around it so that all of the 12 will touch it. The arrangement will be symmetrical and the group will resemble a sphere. As there is no other equally symmetrical arrangement of spheres it is reasonable to assume that 13 atoms are the nucleus for any larger number. Hexadecane, $C_{16}H_{34}$, the largest molecule usually found in kerosene, has 50 atoms. Such a molecule would be likely to have 13 atoms inside and 37 on the outside. While 37 atoms would not quite symmetrically cover the 13 inside ones, if all of the atoms were rigid and unyielding, still there would perhaps be enough elasticity to the whole

*Paper presented at the semi-annual meeting of the Society of Automotive Engineers.

mass to allow the outside to be fairly symmetrical; there would therefore be three layers of atoms in such a molecule.

Molecules are thought to be vibrating and rather reacting on one another as they come near each other at rates depending upon their temperatures. In a mixture of combining proportions of air and fuel molecules the molecules of fuel, nitrogen and oxygen could bombard each other for days without starting oxidation, as it seems that some forms of chemical action between molecules are impossible. We know that two atoms, or one molecule, of hydrogen unite with one atom, or one-half molecule, of oxygen, and that one atom of carbon unites with first one atom of oxygen and the carbon monoxide formed by this union later unites with one more atom of oxygen. In other words a hydrogen molecule is satisfied with an oxygen atom, while a carbon atom requires an oxygen molecule but it can only use half of it at a time. It seems certain that the oxygen must be dissociated and ionized before combustion can begin. It is known that the radiation of a hydrogen flame is entirely in the ultra violet; that ultra violet rays dissociate and ionize oxygen; that oxygen ions spontaneously ignite many organic substances. Other means of producing oxygen ions will be discussed later, but as the blue flame of the electric spark we use for ignition is sufficient to ionize oxygen we are now ready to start the combustion of a 50-atom fuel molecule.

Beginning of Combustion

The electric spark ionizes enough oxygen to start the combustion of some one or more of the 37 atoms on the outside of the molecules. The ultra-violet rays from the burning of the first atoms ionize enough oxygen for the next few atoms but evidently not much more, for the blue flame never "runs away" or causes detonation as it would likely do if there were a large excess of ions. During the combustion of the outside layer of the molecule each atom is being bombarded by molecules of nitrogen and molecules and charged ions of oxygen. As the fuel atoms burn they send out new molecules of water and carbon dioxide, two first-class commercial fire-extinguishers, to replace the oxygen with which they united. If we imagine the atoms in the outside layer of the molecule to be about $C_{12}H_{25}$, there would be 24½ new molecules of carbon dioxide and water to replace the 24½ molecules of oxygen used. The flame during the entire combustion of the outside layer of atoms is the perfectly unobjectionable transparent blue flame of almost entirely electrical properties with which every housewife is familiar from long use of it in the gas range or blue-flame oil-stove.

When this combustion started, assuming that there were no burned gases present from a previous explosion, each fuel molecule was surrounded with 125 N_2, and 33 O_2, but when the 37 outside atoms have burned away we find 125 N_2, 12 CO_2, 12½ H_2O and only 8½ O_2. It would be extremely difficult, if not impossible, to propagate a flame in a cold mixture of these proportions. A hydrocarbon flame cannot be propagated in an atmosphere containing less than 17 per cent of oxygen. With 149½ other molecules in the way, all of them the very best kind of fire-extinguisher, the 8½ molecules of oxygen must have considerable time if they are to reach the remaining fuel atoms. In the meantime the 13 inside atoms have been subjected to the full flame temperature in the absence of air. If heated sufficiently in the absence of air all hydrocarbons will dissociate into hydrogen and lamp black. Probably some of the atoms immediately recombine into much smaller molecules; conditions at this time favor the formation of very small, highly endothermic hydrocarbons, such as acetylene C_2H_2; but in any event there is much free hydrogen and free carbon.

Free carbon atoms tend to form aggregates of tangible size, far too large to burn quickly, among which the free nascent hydrogen burns, heating them to incandescence. The flame now becomes first red, next yellow, then intensely luminous, opaque and radiant. The interstices between the solid carbon particles act as miniature refractory-lined reverberatory furnaces in which the free hydrogen is burned, thereby raising the temperature of the burning mass several hundred degrees. When the flame was in the stage of burning the outside layers or the blue stage only about 8 per cent of its energy was in the form of radiant heat; now more than 30 per cent of it is radiant.

When dissociation or cracking occurs at high temperature there is a large production of charged ions of probably all constituents of the mixture. A pressure wave, per se, probably could not be made to travel through molecular air in excess of the velocity of sound but charged ions undoubtedly greatly exceed that velocity. We will imagine that by this time one-quarter of the mixture is inflamed. The flame-front is still blue but the flame around the spark-plug, having been ignited first, has burned off the outside layers of the fuel molecules and has, by reason of the dissociation of the inside layers, arrived at the white-flame stage. Radiant heat with the velocity of light, and charged ions at something greater than the velocity of sound, are being sent out by the white-flame spot. The transparent blue-flame area between the flame-front and the white spot offers no resistance to the radiant heat and probably not very much resistance to the passage of the ions.

The vapor of hexadecane ($C_{16}H_{34}$) is very dense and opaque as the molecules are very large. Radiant heat is incapable of heating transparent vapors or gases, but it is absorbed in great quantities by a vapor as opaque as that of hexadecane. Heavy-hydrocarbon vapors when subjected to radiant heat of a moderate temperature will crack into smaller hydrocarbons when the cracking is done in the presence of enough air or neutral gas, but if subjected to radiant heat of a high temperature, if in the presence of air, they will ignite as they crack. Neither the radiant heat nor the charged ions can penetrate the dense cloud of vapor beyond the flame-front to a very great depth, but between them they instantly crack some of the molecules and ignite a very large quantity of highly compressed unburned mixture. This action causes a sudden severe increase in pressure, which, on a time and pressure diagram, shows a high peak occurring some little time after ignition.

This new flame very soon reaches the white-flame stage and causes perhaps another auto-ignition of a still more remote portion of the unburned mixture, causing a second pressure-peak. The more opaque fuel molecules would show a greater number of auto-ignitions or pressure peaks than those of less opacity. It is easy to imagine that if a cylinder were large enough the pressures and temperatures would ultimately accelerate auto-ignition to a detonative rate of burning. Auto-ignition is often seen in forest and prairie fires where ignition occurs ahead of a flame-front when there is no possibility of sparks being carried to the area ignited. In experiments with burners auto-ignition is often seen when opaque vapor becomes ignited from a white flame some distance away with which the unignited vapor has no connection. There is little probability that a pressure wave causes auto-ignition as it would simultaneously ignite the whole body of unignited mixture, and we know that kerosene, for example, usually gives three pressure peaks, fuel oil five, etc., which seems consistent with the differences in the opacity of their vapors. There is no doubt that acetylene is occasionally formed and detonated. A glass window in the cylinder of a detonating engine on rare occasions shows a flash that is much more blinding; the noise is much louder than the ordinary detonation. Apparently this happens only with rich mixtures and an early spark.

It should not be imagined that the rate of oxidation increases after a dissociation, for such is far from being true. The rate of *inflammation* increases very considerably, but a careful study of the mixture proportions and ingredients after dissociation occurs will show that further oxidation, of the carbon at least, cannot be otherwise than a very slow process. Rich mixtures and unvaporized fuel greatly aggravate our combustion troubles. Inasmuch as it is positively known that hydrogen and carbon require definite quantities of oxygen for their combustion, it is not likely that we will ever be able to use rich mixtures, as we now use them, without undesirable complications. Unvaporized fuel has little opportunity to burn in a normal manner, as by the time it is vaporized and ready to burn the oxygen supply is much depleted and the dilution with burned products makes it exceedingly difficult for the oxygen to reach it in time to oxidize any of it before dissociation occurs.

Inoffensive Combustion

Having studied a very inefficient type of combustion, we should now study the requirements and characteristics of the inoffensive variety. It should be understood that unless complete dissociation occurs immediately previous to ignition, any kind of a visible hydrocarbon flame cannot be propagated without an initial area, or period, of transparent blue flame, in which the air and fuel are in explosive proportions. Whether the fuel is burned in a supporting atmosphere, as a homogeneous explosive mixture, or even in a complete inversion of combustion, i. e., the burning of air in an atmosphere of fuel, makes not the least difference with the flame characteristics of color in the initial area or period. Entirely green, lavender, red, yellow or white flames cannot be propagated except as above stated, nor can they be maintained if too widely separated from transparent blue flame. If a yellow flame is examined through a yellow color-screen, it will be found to be permeated with a thin blue flame, and if a supporting atmosphere is available it will be seen that the yellow spot is entirely surrounded by blue flame. This is also true of spots of green, red and white when examined through the proper color-screens. In the oxidation of stable fuels spots of green, red, yellow or white indicate either a temporary or a permanent lack of oxygen, and the fuel atoms that actually cause spots of those colors are not at that instant burning. Hydrogen makes no visible flame; nor does carbon in burning to carbon monoxide; carbon monoxide usually burns with a transparent blue flame; therefore, a transparent blue flame is the only *visible* sign of oxidation. Spots of any other color indicate the cracking of the fuel into new smaller hydrocarbons and the large production of carbon monoxide, or the complete dissociation into free carbon and free hydrogen.

In the blue flame the reactions are simpler, more complete and the flame is more compact than any other. The molecules are in more rapid vibration and the oxidation is completed in much less time than when dissociation occurs. It has only about 8 per cent of its energy in the form of radiant heat, it is incapable of depositing soot, and its progress is not seriously affected by contact with cold surfaces. The only known requirements of blue flame are enough air and a fuel that will remain in the molecular state until fully oxidized. Nearly all liquid and gaseous hydrocarbons can be burned with an entirely blue flame, but, beginning with molecules of 12 atoms, more time for the burning must be given as the molecules become larger. Leaving out the ethers, the acetylenes and a few other hydrocarbons that are incapable of burning without more or less explosive dissociation, it can be said that any fuel molecule of 12 atoms or less will burn with an entirely blue flame under any pressure so long as there is no excess fuel.

There is, of course, what might be called a gradual decomposition of the fuel molecule even in a normal blue flame. Products of a limited oxidation of kerosene by catalytic flameless combustion are composed of a large number of alcohols, aldehydes, acids, and saturated and unsaturated hydrocarbons. In the green area of the Bunsen flame there is a very great amount of cracking into new molecules, but so long as complete dissociation does not occur the flame does not become luminous. In the so-called wickless blue-flame kerosene-stoves small jets of air are burned in an atmosphere of kerosene vapor until the fuel molecules are cracked down so small that they will burn above the stove in a supporting atmosphere without luminous flame. It is apparently impossible to produce complete dissociation when enough air or neutral gas is present.

Fuels of the benzol series can seldom be made to burn explosively with a white flame unless a great excess of fuel and very high compressions are used. They can be caused to dissociate and make a cloud of black fluffy carbon, but as benzol series molecules are all small, they do not dissociate until practically all of the oxygen is used; there being very little oxygen left after dissociation, the free hydrogen usually cannot burn enough to heat the carbon particles to incandescence. Used in stoichiometrical proportions such fuels probably cannot be made to detonate under any pressure. Fuels of the saturated series, when used in excess, have more tendency to become luminous; they are almost certain to have some large molecules as they are nearly always a mixture of a large number of different members of the series.

For every fuel molecule larger than 12 atoms there is a rate of oxidation that will cause it to dissociate, but for use in present explosive engines a molecule of 20 atoms or less would burn fast enough to be perfectly satisfactory, provided that there were no highly endothermic bonds in it. Its vapors would be so nearly diathermous that they could not be much affected by radiant heat. Fuels having the largest molecules have the most opaque vapors. The large molecules cannot burn rapidly without dissociation. The excess of ions from the dissociation and the radiant heat from the incandescent free carbon particles cause auto-ignition in unignited portions of the mixture. Therefore, to burn heavy fuels with a blue flame in present engines, one or all of the following remedies should be used:

(1) Thoroughly vaporize fuel
(2) Retard speed of oxidation
(3) Crack opaque vapors before ignition by use of radiant heat
(4) Raise compression and use reasonable excess of air
(5) Ionization previous to ignition
(6) Induce great turbulence
(7) Destroy reverberatory action of combustion-chamber walls
(8) Eliminate pockets in the combustion chamber
(9) Locate spark-plug in exact center of combustion-chamber

Oxidation and Flame Propagation

Oxidation can be retarded by careful cooling of the combustion-chamber, and by the use of plain diluents such as an excess of air or cool exhaust gas. The compression should be high, 125 lb. or more, to gain in thermal efficiency. The diluents can then be used with more effect and economy than when the dilution is secured by lowering the compression. It might be worth while to try a very small amount of chlorine as a diluent, as this substance is an ionizer and whenever a hydrogen atom is freed from a molecule, leaving the molecule in an unstable equilibrium, the chlorine would be likely to replace the hydrogen and preserve the molecular structure.

To best promote flame propagation the oxygen might be

A New Method of Cooling Automotive Engines

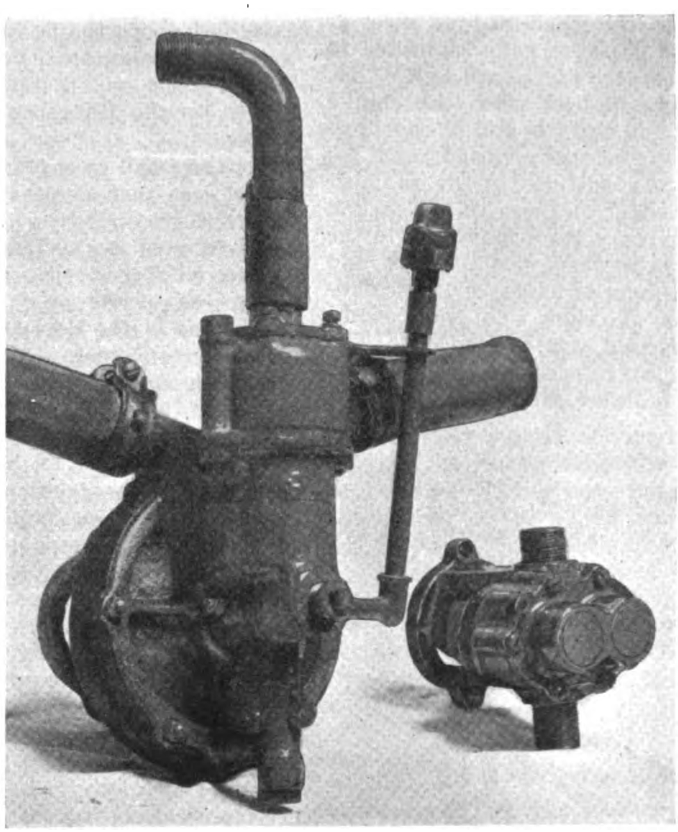
Normal temperature of jacket is raised above the boiling point of water by using a closed system in which steam is generated at about 5 lb. per sq. in. pressure. Radiator not completely filled with water.

By P. M. Heldt

THERE has been very little progress in cooling systems for years past, aside from the introduction of the thermostat, which is designed to ensure quick warming up of the engine when starting from cold and maintaining a fairly constant jacket temperature thereafter. The necessity for quickly heating up the engine and for maintaining it hot irrespective of load changes arises from the low volatility of our present fuel. There is no doubt that the higher the cylinder wall temperatures, within the limit at which trouble begins to be experienced from preignition or burning of the lubricating oil, the more rapid and complete the combustion of the fuel, and the less the trouble from crankcase oil dilution. Air cooling, of course, affords these higher cylinder wall temperatures, but the great majority of engineers seem disinclined to tackle the problems involved in the development of a successful air-cooled engine.

Samuel W. Rushmore, well known to the automotive industry as a former manufacturer of searchlights (headlights) and of an electric starting and lighting system, has recently developed a cooling system which is in a way intermediary between the air cooling and the ordinary water cooling systems. Water is used as the cooling medium, but the jacket outlet temperature is constantly maintained above the boiling point of water. There is ordinarily little or no water in the radiator above the bottom tank. The radiator core is filled with steam to a certain height depending upon the relation between heat absorption in the cylinder jackets and heat dispersal per unit of core surface. It is obvious that the radiator becomes much more effective with a cooling medium at 220 to 240 deg. on the inside of the core than with water at from 100 to 200 deg., especially at high atmospheric temperatures.

The great practical advantage of the new system, and which should ensure for it a wide field of application, is its simplicity. Imagine an ordinary water cooling system with pump circulation and having a thermostat in the top connection between jacket and radiator. The thermostat is removed and the connection to the top tank of the radiator eliminated. The outlet from the jacket is connected to the bottom tank of the radiator, the radiator overflow pipe is provided with a blow-off valve set to about 5 lb. per sq. in. and the centrifugal pump is replaced by some type of positive pump. (Mr. Rushmore has so far used gear pumps.) The bottom tank of the radiator is preferably enlarged in size. This completes the system.



Centrifugal pump and thermostat (left) of Cadillac car and gear pump (right) which Mr. Rushmore substituted for these parts

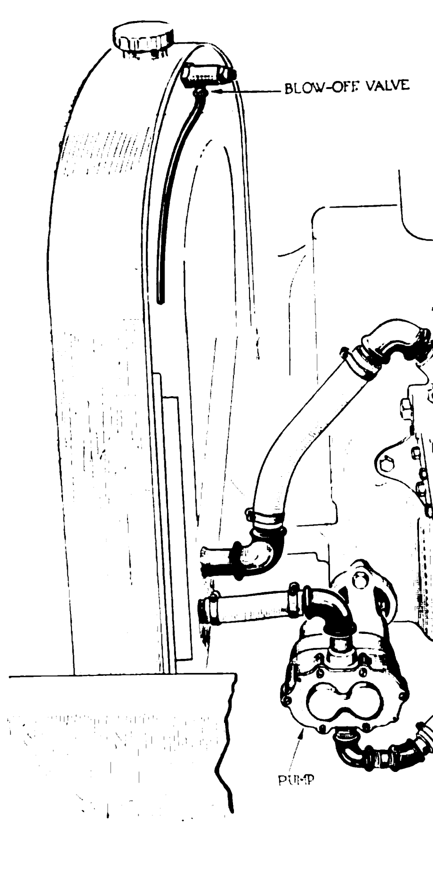
Even though the thermostat is removed, the same advantages are obtained as with the ordinary system with thermostat, because when starting a cold engine there is no circulation of the cooling fluid through the radiator, and the engine therefore quickly approaches its normal working temperature. In fact, the cooling action of the radiator core begins only when the water leaving the jacket reaches the boiling point. This very fact also insures a nearly constant temperature throughout the operating range because the maximum temperature in the system cannot greatly exceed the boiling point, as it is limited by the setting of the blow-off valve, and as soon as the water outlet temperature drops below 212 deg. the cooling action ceases almost entirely, so even at very light loads the water outlet temperature is constantly above 212 deg.

Mr. Rushmore has applied the system to a number of cars, including a Cadillac, a Crane-Simplex, a Studebaker, Mack 5½-ton truck and a Locomobile. The Crane-Simplex is fitted with thermometers and pressure gages for test purposes. A pressure gage of the Bourdon tube type is connected to the engine jacket outlet, as is also a thermometer of the circular dial type, the dial being mounted

on the toe-board. A mercury column pressure gage is connected to the top of the lower tank which has a nipple soldered to it on the forward side, over which the end of a rubber tube is slipped.

Ordinarily only the lower tank is to be filled with water, and to this end it is provided with a filler spout centrally in front, but to show that no harm would result if a driver unfamiliar with the system filled the radiator to the top, Mr. Rushmore did this and then started on a drive, accompanied by the writer. The thermometer showed a rather rapid rise in temperature at the jacket outlet, and after some time cold water began to escape through the blow-off valve. Thereupon the engine was shut down, and this greatly hastened the expulsion of the surplus cold water, no doubt because, when the fan is stopped, the cooling action is greatly reduced and the heat stored in the piston and other metal parts of the engine is transferred to the cooling water and generates steam. Owing to the use of a positive pump, circulation stops completely when the engine is shut down, and the generation of steam in the jacket manifests itself in blowing off all water in the radiator core.

The car was driven a considerable distance over a variety of roads, the route followed including one long hill with grades up to 18 per cent, and the system appeared to work very satisfactorily under all conditions. Most of the time a large part of the radiator was screened off by a sheet of pantasote in front of it. The pressure gage connected to the jacket outlet showed a pressure of from 5 to 7½ lbs. per sq. in., the pressure being highest when the engine had run for some time under full throttle and at considerable speed. The water outlet temperature varied from 230 to 240 degrees. The pressure conditions in the radiator were apparently quite independent of those in the jacket, the pressure shown by the mercury gage connected to the bottom tank varying roughly between plus 3½ lbs. and minus 3 lbs. per sq. in. Thus here is under certain conditions a vacuum in the radiator. To show what these conditions are the following experiment was carried out. The engine was run for a while at considerable speed with practically the whole of the radiator core screened off by the pantasote, so that the radiator filled with steam practically to the top and showed considerable pressure. The screen was then entirely removed and the car driven down an incline where very little power was required and consequently very little heat was absorbed by the jacket water. The mercury column very soon showed a vacuum in the radiator, while pressure above atmospheric continued at the jacket outlet.



Sketch showing system as applied to Cadillac car.

This difference in the pressures of the jacket and radiator indicates that the pressure shown by the gage connected to the jacket outlet is largely due to the friction head in the pipe leading from the jacket outlet to the bottom of the radiator. The pressure in the cooling circuit naturally will vary slightly from point to point and the pressure at any particular point will depend upon three factors. There is first the pressure due to the static head, which is nil at the highest point in the circuit, a maximum at the lowest point and varies uniformly with the distance between the two points. Then there is the pressure due to the friction head, which is nil at the inlet to the pump and increases around the circuit to the outlet of the pump in a non-uniform manner depending upon the sectional area of the water passage. Finally there is a pressure due to the temperature of the water, which is the same at all points of the system. To make this plain, assume that there is no circulation. Then if any part of the water is raised above the boiling point, steam will be generated and pressure created, but the pressure per unit area will be the same on all interior walls of the cooling system, except for the difference due to the effect of gravity on the water.

As the small gear pump employed delivers to the engine jacket less than one-tenth the volume of water necessary where the heat is transferred to the radiator by the usual water circulating system, the return pipe from the jacket to the radiator carries chiefly steam, with which is carried along the excess or unevaporated water, and thus the resistance to the flow is somewhat greater than if water alone were present. On the Cadillac, on which the system has been applied, the outlet pipe is much larger in proportion to the size of the engine, so that the friction head never exceeds ½ lb. per sq. in. Although, by making the steam outlet pipe of proper diameter and by avoiding sharp bends the friction head need not exceed ½ lb. per sq. in., it has been found that at the lowest engine speeds the centrifugal pumps usually employed will not give even that much pressure and therefore a positive pump is required to insure proper circulation at idling speeds. This is the only reason a positive pump is required, and not the pressure due to the temperature of the water, as this pressure is equal at the pump inlet and delivery sides and does not affect the working of the pump.

Only a comparatively small pump is needed, for the reason that in this system the heat absorbed by the jacket is used to convert water into steam, instead of merely raising its temperature from 10 to 20 deg. The latent heat of one pound of steam is 966 thermal units, whereas the heat required to change the temperature of one pound of water 20 deg. Fahr. is only 20 thermal units. Hence it would seem that with this system the water needs to be circulated only one-fiftieth as fast as with the ordinary system. However, extreme conditions must be provided for and we have no assurance that a temperature gradient of 20 deg. in the ordinary system will take care of extreme conditions; besides, it is not safe to figure on all of the water being vaporized during each round, which would mean that only steam would pass through the return pipe. Therefore, while a much lower rate of circulation is permissible than with the ordinary system, it would not be safe to cut down the circulation in the proportion above mentioned.

One feature of the new system about which there was

some uncertainty at first was the ability of the condensate to descend in the very narrow passages of the radiator core when steam is constantly passing upward. This, however, has caused no difficulty whatever. The lower part of the radiator core is constantly filled with steam which is being condensed by the cooling action, while the upper portion of the core is absolutely cold. There is usually a sharp line of demarkation between the hot and cold sections, this line rising and dropping with the conditions of engine operation. The upper part of the radiator is filled with air and water vapor which is normally under a slight pressure. This is a fortunate thing, because if the radiator were filled with steam to the top, if the driver removed the radiator cap in a careless manner, he might possibly scald his hands.

In the earlier experiments Mr. Rushmore ran a pipe from the inlet to the bottom of the radiator part way across the tank, this pipe being drilled with a considerable number of small holes in the bottom and sides, with the idea of separating the water from the steam without forcing any of the water into the passages of the core. It was found, however, that this precaution was unnecessary, and he now employs only a simple pipe connection to the lower tank.

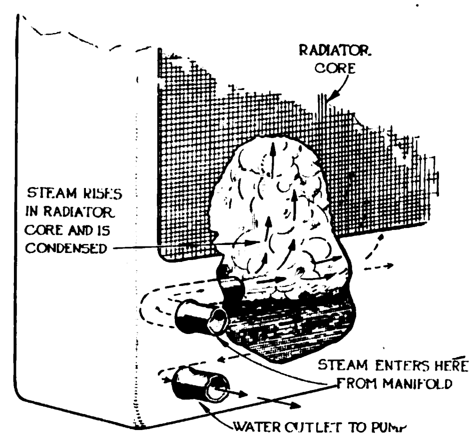
That neither the splashing of the water in the lower tank nor the returning condensate cause any noticeable obstruction to the upward flow of the steam is accounted for by the fact that with an air-cooled radiator the amount of steam condensed per minute per unit of cooling surface is extremely small. In the case of the Cadillac. the maximum evaporative effect at full load is only about one pint of water per minute which, divided among the 150 vertical tubes in the standard Cadillac radiator, amounts to only a few drops of returning condensate per minute per tube, and in any type of air-cooled radiator the flow of steam is so slow that the condensate merely trickles downward without interference. In fact tests with a radiator fed with steam from a stationary boiler and cooled by a powerful electric fan have shown that even though excess steam be forced out of the top of the radiator, none of the condensate appears at the top.

So far the system has been adapted only to existing cars, and therefore probably has not worked under as favorable conditions as would be possible on a car specially designed with it. As to its advantages, there can be no doubt that it ensures more complete combustion of the fuel, especially at small engine loads, and tends to minimize crankcase oil dilution. It is simpler and cheaper than other systems, and ensures a quick heating of the engine to the normal working temperature and a fair regulation of that temperature. The danger of the fine passages of the radiator becoming clogged with deposits from limy water is eliminated, and owing to the much greater cooling effect of a unit radiating area when in contact with steam than when in contact with water at the normal jacket outlet temperature, probably a much simpler and more robust core construction could be used, or the depth of the core diminished.

No stock cars are as yet being fitted with the system, but it will probably be applied to a number of 1922 passenger car models. It is particularly applicable to motor trucks, for it tends to reduce crankcase dilution due to the engines running idle for long periods in cold weather. On the Mack truck above referred to a considerable saving in fuel was shown and, by reason of the higher radiator temperature, the system provides ample cooling capacity, even in mountainous country where the boiling of the water in the ordinary system often greatly reduces the working capacity.

A further important advantage over thermostat control is that as the radiator core contains no water it cannot freeze when on the road, as often happens unless a large percentage of alcohol is employed. Manufacturers employing the thermostat control advise customers to cut the thermostat out during freezing weather, the very time automatic temperature control is most needed. Several cars equipped with the Rushmore system were in constant service all through the past winter and gave no trouble from freezing.

As the temperature of the jacket water will depend upon the steam pressure carried, an inexpensive reducing valve



Sketch showing location of radiator inlet and outlet in Rushmore system.

may be put in the pipe leading from the jacket to the radiator to hold the jacket temperature constant at all loads regardless of the percentage of alcohol that may be employed to prevent freezing when the car is left standing for long periods in cold weather. With the present-day water cooling system using alcohol the maximum temperature cannot much exceed 175 deg.

The motometer is now connected to the engine jacket direct with dial on dashboard where it can be seen more easily and particularly at night and where it is not so easily stolen.

The new system should be of particular value on airplanes. Airplane radiators are now mostly of the hexagon tube type. It has been found that with the steam system the tubes can be placed much closer together, thus effecting a reduction of fully 20 per cent front end area for the same amount of air cooled surface. As the cooling effect per unit of cooling surface is from 50 to 80 per cent greater with steam, the area may be still further reduced, and in consequence of the saving in weight of water, additional fuel may be carried and the speed of the plane increased.

A Wire Wheel with Bolt Attachment

THE popularity of the bolt attachment for demountable wheels in Great Britain has induced the Dunlop Company to introduce a fitting of this kind for their wire wheels. The center of this wheel has a drum of pressed steel from which the usual wire spokes lead to the tire rim. The drum is secured to the hub by means of six studs and nuts in accordance with the usual arrangement of this principle of fixing. It thus eliminates threaded hubs and special locking devices for the wheel nut of the usual type. It is claimed that this arrangement not only simplifies the form of attachment and thus recommends it to the user, but it also represents a cheaper form of construction. In appearance, however, it suffers as compared with the usual type, for the central drum gives it a somewhat heavy appearance by comparison.

S. A. E. SUMMER MEETING

Developing a High Compression Automotive Engine

This summary describes some of the problems involved in the development of a Diesel type automotive engine. Particulars given apply largely to factors involved in design and construction of the fuel injection system.

AN S.A.E. Summer Meeting paper prepared by Fred C. Ziesenheim, bearing the above title, naturally divides into three parts. The first relates to the fuel problem, giving the proportion of gasoline, kerosene, gas and fuel oil and lubricating oil produced from crude petroleum in 1920, the change in the distillation curve of gasoline from 1915 to 1920, and the variation in the prices of crude petroleum and its distillates from 1913 to 1920, etc.

In the second part all present internal combustion engines are divided into three classes, low compression, medium compression and high compression. The first class includes all automobile engines, the second class the hot bulb, surface combustion or semi-Diesel engines, and the third group the Diesel engines. The advantages and disadvantages of each class are given.

In the third part Mr. Ziesenheim describes some development work on mechanical injection systems for high compression engines which he has done at the Mechanical Laboratory of the Carnegie Institute of Technology. A small surface-ignition engine was used, after increasing the compression-pressure to 500 lb. per sq. in. by the substitution of a new piston and a new cylinder-head. The engine is a vertical two-stroke-cycle two-port type, with crankcase precompression. The bore is $5\frac{1}{2}$ in. and the stroke is 6 in., which is reduced to $4\frac{3}{4}$ in. by the width of the ports. The compression of 500 lb. per sq. in. was selected for the initial tests, as it can be decreased when desired by simply raising the cylinder-head. The compression necessary for auto-ignition depends upon the ignition temperature of the fuel; the temperature from the compression must be high enough to insure starting with the engine cold. The lowest compression that will permit cold starting is about 350 lb. per sq. in.

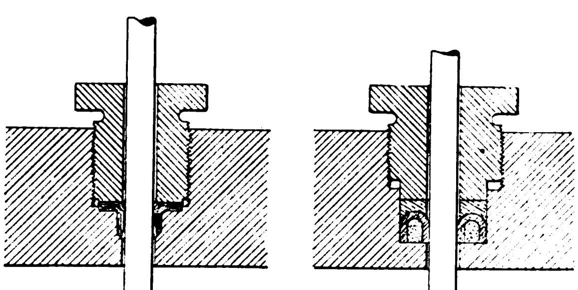


Fig. 1—Two types of leather valve packing, the packing at the left is of the flange type while that at the right is what is termed a U-packing.

Ignition temperatures of fuels as applied in engines cannot be satisfactorily determined by ordinary laboratory equipment, as the manner of injection and the temperature of the cylinder walls are not considered. Apparatus consisting of a combustion chamber fitted within a gas furnace and equipped with an injection valve, and pressure, temperature and time recording devices has been used by the British Admiralty Experimental Laboratory for determining the ignition temperatures and the time interval between the moment of injection and the moment a pressure rise is indicated in the combustion chamber.

Mechanical injection can be accomplished by variable pressure, in which the fuel injection valve opening is controlled by fuel pressure difference; or by constant pressure, in which the fuel injection valve opening is controlled mechanically by means of a cam and lever and the fuel pressure is constant.

The variable type of compression valve consists of a spring-loaded differential plunger that opens when the fuel pressure exceeds the spring resistance. The fuel pressure variation producing injection is independent of the action of the fuel pump and governor, which action should cause the injection to take place in accordance with the conditions insuring optimum pulverization. In addition, the quantity of fuel to be injected must be metered accurately, and the time and duration of injection must be under control. The small quantity of fuel to be injected before each working stroke is responsible for some of the principal problems in the design of a small high speed engine. In the experimental engine under discussion the quantity of fuel injected per revolution at full load is about 0.1 cc.

By the usual method of metering the fuel, the governor holds open the suction valve or a by-pass valve during the initial portion of the pump stroke and, upon the closing of the valve, the fuel is pumped into the injection valve. Another method consists in varying the stroke of the pump plunger by a wedge which is actuated by the governor. With accurate metering by the fuel pump the problem then consists in discharging exactly the desired quantity of fuel from the injection valve, and in discharging uniform quantities of fuel for uniform speed and load conditions.

Conditions which may interfere with or prevent the injection of the metered quantity of fuel are the (a) elasticity of the fuel, (b) elasticity of fuel-containing system, (c) elasticity of entrained or entrapped air and (d) leakage within the fuel system. The elasticity of the fuel at the pressures used is approximately 2 per cent. This makes it necessary that the quantity of fuel in the system, between the pump and the ignition nozzle, be the least possible.

To overcome elasticity in the fuel containing system it is obvious that the fuel pipes, connections and the like must be made heavy enough to insure absolute rigidity. The poor injection action of many surface-ignition engines can be attributed to failure to meet this condition. Air gets into the fuel system by being entrained with

the fuel, by leakage past the injection valve during the compression stroke and by leakage during the suction stroke of the fuel pump. It is sometimes entrapped during the assembly of the fuel system, or it can accumulate while the engine is idle. Air is so highly elastic that a small bubble in the fuel system will become a minute volume during the working stroke of the fuel pump but, when the pump starts on the suction stroke, the bubble expands and prevents the pump from drawing in a full fresh charge of fuel. During the following working stroke of the pump either no fuel will be discharged or the quantity will be less than that desired. This produces an erratic "hit and miss" injection action that may cause the injection of an excessive quantity of fuel, thereby producing abnormal pressures in the cylinder. Provision must be made for draining the air from the highest point in the fuel system, preferably in the injection valve. The fuel system must be arranged so that the air will not accumulate at any other point.

The quantity of fuel in the system, particularly in the injection valve, should be a minimum in order to secure as complete and rapid a discharge of the fuel and entrained air as possible. Fuel leakage occurs around the pump plunger packing gland and around the packing gland or similar device of the injection valve stem. High pressure packing glands are a source of trouble. A form of plunger packing used with satisfaction in hydraulic machinery at pressures exceeding that encountered in injection engines is shown in Fig. 1 and consists of Vim leather molded into the shapes shown. In the flange packing at the left the nut clamps only the flanged portion; the body of the packing has clearance so that the liquid can surround and force it tight on the plunger. In the U-packing at the right the pressure of the liquid within the U forces the leather against the plunger and the walls of the receptacle, thus sealing the joint. The space within the U can be filled with hemp to prevent collapse of the packing when there is no pressure acting. Leakage may occur at the suction or discharge check-valves, which are usually placed in multiple. Poppet, cylindrical and ball-check valves are shown in Fig. 2.

A form of pipe connection used satisfactorily in Diesel engine practice is shown in Fig. 3. The male part is made of brass or copper, the tubing being brazed into it.

The simplicity of the injection valve is the advantage of the variable pressure method; the operation of the valve is entirely automatic, avoiding the complication of valve-gear. The quantity of fuel for each charge can be metered accurately by simple and reliable mechanism incorporated within the fuel-pump, but the disadvantage of the method lies in its inability to discharge the desired quantity of fuel at the correct time and in the manner necessary for achieving complete combustion. The reasons for this inability have been enumerated. Of these (*a*) the elasticity of the fuel and (*b*) the elasticity of the fuel-containing system can be partially obviated by proper design, but (*c*) the elasticity of entrained and entrapped air and (*d*) leakage within the fuel system are more difficult to control. Due to the small quantity of fuel to be discharged the presence of any air will interfere with or prevent regular injection of the fuel, and a very slight

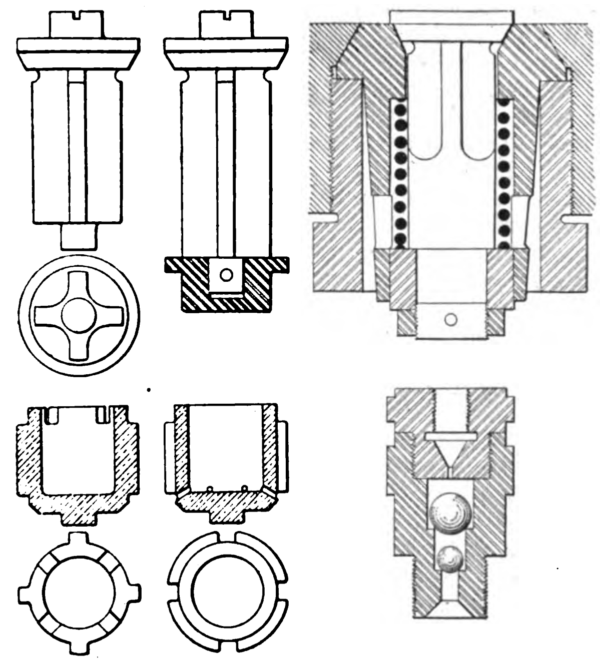

Fig. 2—Types of poppet, cylindrical and ball check-valves used in internal-combustion engines

leakage can easily equal the quantity of fuel it is desired to inject. These adverse conditions make the variable pressure method practicable only for large slow speed single-cylinder engines, where the amount of fuel to be injected is a relatively large quantity. The method is in use on all surface ignition engines and is therefore to be found on many high compression engines developed by companies building both types. The high compression engines using this method are usually of the slow speed single-cylinder type, which can be assembled also as twin-cylinder engines. The conclusion arrived at is that this method is not satisfactory for high speed multiple-cylinder engines suitable for automotive purposes.

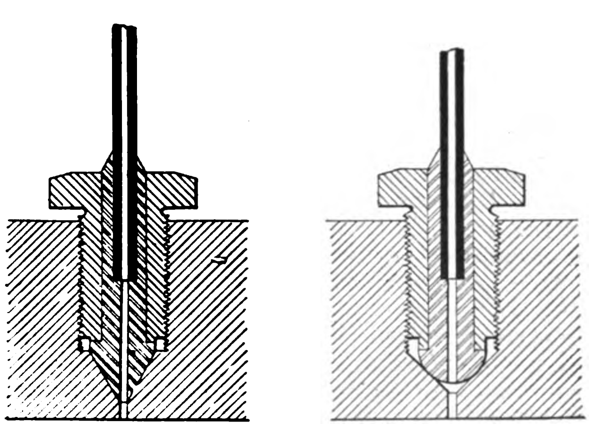

Fig. 3—A form of pipe connection used with great satisfaction in Diesel engine practice

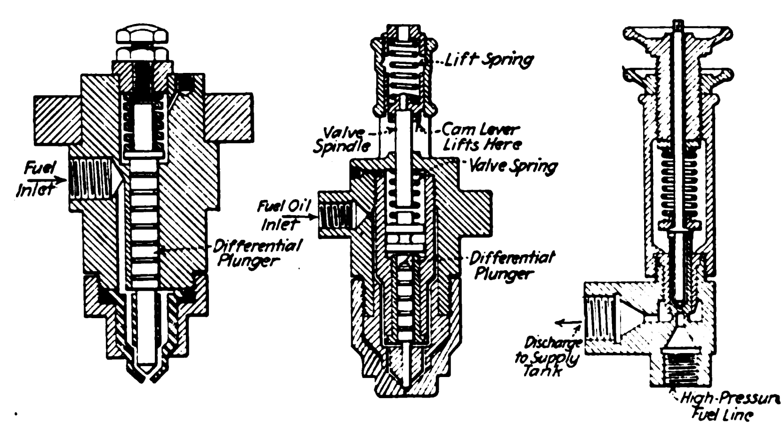

Fig. 4—Three types of injection valve. The valve at the left is controlled by the fuel-pressure difference and that in the middle has the fuel opening controlled mechanically by a cam and a lever. The valve at the right is pressure-regulating valve

The fuel is supplied to the injection valves of all the cylinders from a single main supply line which is maintained at constant pressure. The fuel injection valve shown in the center of Fig. 4 is mechanically operated by a cam and lever; the metering of the quantity of fuel for injection and the time and duration of the injection are under control of the governor acting on the fuel cam and lever. The fuel pumps are designed to pump two or three times the quantity of fuel necessary for full load conditions. The fuel pumps are made preferably from a forged steel block; the pump cylinders and valve seats being machined in the block. Packing glands for the pump plungers have been shown in Fig. 1 and the check valves in Fig. 2. Due to the high pressures that the pumps work against, the pump shaft and the eccentrics must have liberal bearing areas and positive pressure lubrication. The use of several plungers of small cross-sectional area reduces the bearing loads. The pressure of the fuel is maintained constant by a pressure regulator holding suction bypass-valves open during a portion of the pump stroke, or by a spring loaded relief valve similar to the valve shown at the right in Fig. 4. The flat seat of the pressure regulating valve gives less trouble from chattering and wear than a mitered seat. The seat parts are made of hardened steel.

The constant pressure injection valve shown in the center of Fig. 4 consists of a differential plunger, spring loaded by a valve spring and also by a lift spring which forces a valve spindle onto the differential plunger. A cam operated lever lifts the valve spindle, relieving the lift spring and permitting the fuel pressure to lift the differential plunger against the valve spring. The movement of the differential plunger removes the injection valve from its seat and permits the fuel to be injected into the combustion chamber. The fuel cam action controls the (*a*) time of injection; (*b*) lift of the injection valve; (*c*) duration of injection; (*d*) quantity of fuel injected and (*e*) manner of injection. Variations in the time of injection can be accomplished by angular advancement or retardation of the fuel cam. The lift of the injection valve and the duration of the injection are determining factors in the quantity of fuel that will be injected. The injection valve lift, determined by the fuel cam lift, must be sufficient to permit free injection of the fuel without dribbling. The duration of injection depends upon the angular period of the fuel cam. As the fuel pressure is constant, the injection valve lift should remain practically constant during the period of injection. Varying the quantity of fuel for different load conditions should be accomplished by varying the duration of the injection period; in other words, varying the cut-off ratio, or the length of the constant pressure line. The rapidity with which the injection valve opens and closes is a determining factor in attaining the conditions of maximum pulverization. With the injection valve filled with fuel maintained at constant pressure and the fuel cam acting directly on the injection valve, the injection action can be much more rapid than with the variable fuel pressure generated by a cam and pump removed from the injection valve.

The constant pressure method is not subject to the adverse conditions which interfere with injection in the variable pressure method. The constant fuel pressure obviates trouble from the elasticity of the fuel and its containing system and also does not permit the entrapped air to expand and cause erratic injection. Any leakage that occurs in the fuel system with the variable pressure method is a wastage from the metered quantity of fuel that it is desired to inject. In the constant pressure method the metering is done within the injection valve so that leakage in the system does not affect the quantity to be injected.

In view of the considerations stated, the constant pressure method is preferable for small high speed engines in that the exact metered quantity of fuel is positively injected at the desired time, and in that uniform quantities are injected for uniform speed and load conditions. The experimental work has shown consistent progress but has not advanced to a point where further disclosure of methods and results is advisable.

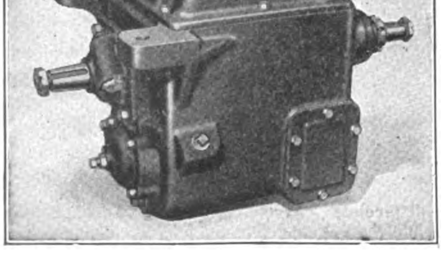
A New Model of Transmission

A NEW model of gearset known as Model 55 has been added to the line of the Brown-Lipe Gear Co. The new product was designed to fill a gap in its range of sizes and has several individual features.

Model 55 is of the main-frame type and in capacity is substantially midway between Models 50 and 60. Regular features are selective gears that give four speeds forward and one reverse; a rear mainshaft bearing cap that takes a speedometer drive, and two S. A. E. standard pads, one on the right and one on the left side of the case, intended respectively for a one-speed power take-off and a pump.

Optional arrangements include either overhead or side shift and—when a power take-off is not used—the mounting of the pump on the right side of the case. Of course, the option of shifts necessitates the selection of one of two forms of case, cover, etc., but the pump can be mounted on the right side at any time by adding to it a 2-in. filler block, furnished by the pump manufacturer.

The illustration given here shows the overhead shift. The side shift type transmission is less in depth by the height of the shifter housing, but slightly greater in width.



New Gearset Model

THE consumption of gasoline in Australia is increasing rapidly and is leading to an investigation of the possibilities of the Commonwealth. In 1910 the consumption was 25,725,000 gallons; in 1915, 43,000,000 gallons, and by 1919 it had increased to 51,000,000 gallons. Although the presence of oil is evidenced by its oozing from the ground in numerous places, drilling has failed to discover deposits of commercial value. The Commonwealth Government has offered a prize of £10,000 to stimulate further search, and the South Australian Government has also voted a bonus of £5,000 to the person or company that first obtains from a well in South Australia 100,000 gallons of crude petroleum containing not less than 90 per cent of products obtainable by distillation. So far the rewards have not been won.

Features of Mechanical Interrupters for Ignition Systems

Part II

In this installment the author describes the features of several commercial types of interrupters and discusses the advantages and disadvantages of these types. This completes the article and thus covers all the important considerations involved in the design of interrupters.

By Harry F. Geist

WE have magnetos made with stationary coils and magnetos made with rotating coils. In the cases where stationary coils are used the interrupter parts are also stationary and the interrupter is actuated by a rotating cam, but in the case of rotating coils, the interrupter parts are also in rotation and co-act with stationary cams for the actuation of the interrupter. In special cases where collector spools or buttons are used the stationary type of interrupter may be used with rotating coil type magnetos, but this construction is the exception rather than the rule. These two general differences in interrupter designs bring out entirely different considerations which are of interest.

In the rotating type of interrupter, all the moving parts are mounted upon the rotating breaker plate as shown by Fig. 1, so that the radius at which the bumper block of the lever arm actuates with the cam is fully twice as great as that of a rotating cam actuating a stationary type of interrupter.

With these two different arrangements, arguments for and against either type of interrupter may arise, but experience with both types has proven that both, in the highly perfected designs of the present day give very satisfactory service.

In order to show the different conditions that obtain in these two different types of interrupter mechanism, Fig. 8 is presented for an analysis.

The bumper of the rotating breaker arm is shown just at the point of striking the stationary cam, at the point O, from which point, instead of following the circular arc OB it follows the line of the cam contour O'A, so that the angle through which the bumper is forced inward may be expressed roughly by BOA, giving the bumper an inward motion equal to AB or M.

If the distance from the arm pivot to the contact point is equal to the distance from the pivot to the bumper, then M will also be the amount of contact separation. At the higher speeds the bumper may receive a throw so that the motion it receives may be greater than the distance AB.

The force tending to hold the bumper against the cam contour or tending to hold the contacts closed will be the force of the spring F_s plus the centrifugal force of the lever arm F_c and plus or minus a force due to the inertia of the arm in its motion M that may be expressed by F_m. It is the usual practice in the design of rotating interrupters to so design the arm that the centrifugal force acting on the bumper end of the arm will be greater than the centrifugal force acting on the contact carrying end of the arm so that the rotation of the interrupter as a whole will give a resultant centrifugal force to the arm that will always tend to aid the spring. This is to assure that centrifugal force will never cause the contacts to separate, but on the other hand, will help to close them and is a very important consideration in the development of rotating types of interrupters.

The force F_m is the most difficult to control. At the higher speeds it may become greater than F_s plus F_c and cause the bumper motion to exceed the amount AB. This force depends upon the mass of the lever arm swinging upon its pivot and upon the rate of bumper motion M. It is controlled to some extent by making the lever arm as light as possible without sacrificing mechanical strength. It is no doubt this force that is responsible for the vibrations of the contacts that was previously discussed.

In order to make a direct comparison, let us assume that it is desirable to have the contacts opening the same amount for the same amount of angular rotation of the magneto rotor in the case of the stationary interrupter and rotating cam. Under this condition, which is represented in Fig. 8, the rotating cam will force the bumper along its contour O'A', so that the angle at which

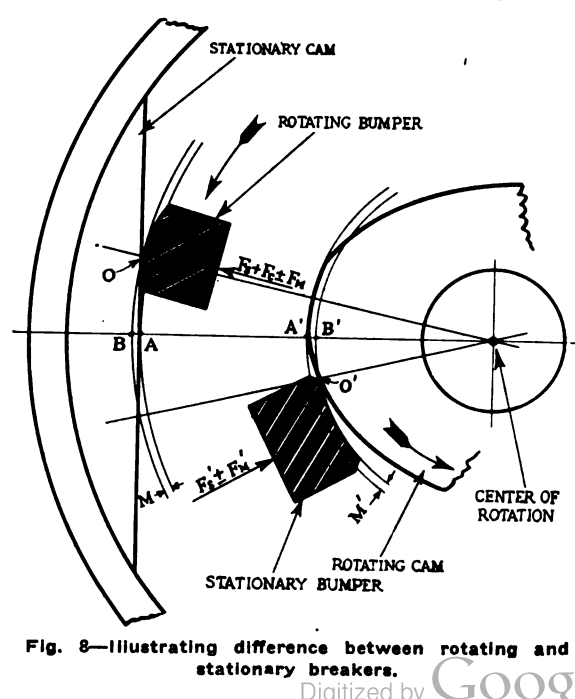


Fig. 8—Illustrating difference between rotating and stationary breakers.

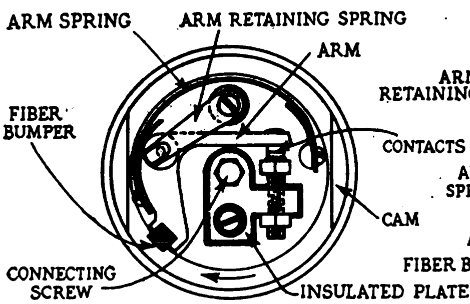

Fig. 9—A much used type of rotary interrupter.

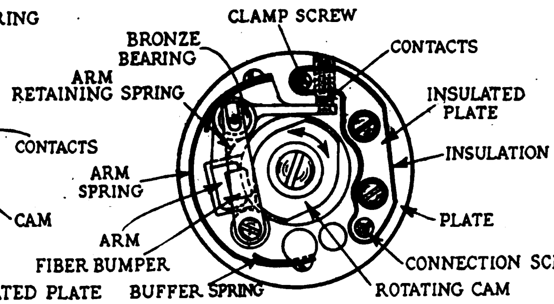

Fig. 10—A widely used type of stationary interrupter.

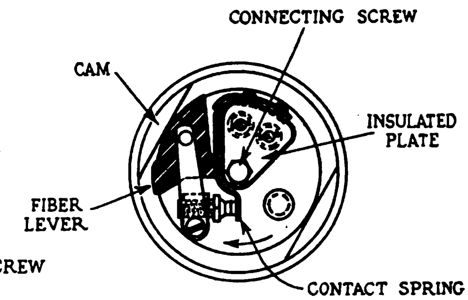

Fig. 11—A well known interrupter of novel design.

the bumper is forced with reference to the cam may be expressed by A′O′B′. This angle is roughly about twice as great as the angle AOB when the radius of action between the rotating cam and the stationary bumper is one-half the radius of co-action between the rotating bumper and the stationary cam, and provided A′B′ equals AB.

For the same rotor speed, therefore, the rotating bumper will travel at twice the peripheral speed of the rotating cam, but in moving inward on an average cam angle of only half as much it is evident that the speed at which the rotating bumper travels the distance M will be the same as the speed at which the stationary bumper makes the motion M′.

The stationary bumper is held inwardly by the forces F'_s plus or minus F'_m, where F'_s is the force of its spring and F'_m is the force represented in the inertia of the arm due to motion M′. Centrifugal force does not enter into play in this type of interrupter. In this stationary type of interrupter, just as was shown for the rotating type, the force F'_m may at higher speeds be sufficient to overcome F'_s and give the bumper a throw such that M′ will exceed O′A′ and may also be the cause of vibrations of the lever arm.

The advantage of the stationary interrupter lies in the fact that it is free from centrifugal force, since it does not rotate. It certainly facilitates the development of an interrupter not to have to take that force into consideration, but on the other hand this same centrifugal force serves to counteract the inertia that comes into play tending to give the arm excessive motion at higher speeds, so that while it may complicate the development, it must be given credit as a valuable assisting force to the spring in holding down the contact motion and the vibrations that the lever arm is subject to.

In general interrupters are intended to open the contacts only from about .015 to .020 inch, and it would seem that for this small amount of interrupter lever action that the possibility of excessive contact separation and of vibrations would not be very great, but experience has shown that these results do take place at times even at average operating speeds.

The following interrupter designs are presented because they show a wide variation in the manner in which interrupters can be designed to meet the conditions set forth in the foregoing paragraphs. They are also excellent examples of exclusive features and distinctive design found in the present day ignition systems.

Interrupter Designs

Fig. 9 shows the features of the complete interrupter illustrated in Fig. 1 and the arm retaining spring that is adapted to hold the lever arm in place upon the breaker plate.

This interrupter is perhaps the best known and most copied of all ignition system interrupters. It is used by a number of different manufacturers both in the United States and abroad. The features that contribute to the success of this interrupter, which is of the rotating type, is the perfect balance of the arm for all speeds at which it is designed to give service. There is just enough mass in the fiber bumper end of the arm which is located farther from the center of rotation than the contact carrying end of the arm to assure just enough centrifugal force to make certain that the contacts will not open due to rotation alone and that the force of co-action of bumper and cam will not give the contacts an unnecessary or an undesirable amount of opening.

The main spring is backed up by two buffer springs, one at each end, that keep the springs from breaking, relieving as they do any tendency for a sharp bend that would produce early fatigue. The cams are oiled by wicks embedded in them. No other oiling is required, hence oil cannot get to the contacts. The centrifugal force due to rotation tends to keep all the oil away from the rotating parts of the interrupter.

For right- or left-hand magneto rotation entirely different interrupters are necessary.

Fig. 10 shows the most widely used stationary type of interrupter. The arm is a drop-forging carrying a platinum contact on one leg and a hard, polished bumper that is formed to have a radius to suit the cam at the other leg. The arm pivot bearing is of bronze and fits a hardened steel pivot, which in some cases is hollow, making it possible to oil the pivot bearing through a vent in the stationary breaker plate. The condenser and primary winding are connected to the interrupter by a common lead that is secured to the insulated plate by means of a screw. This insulated plate, of course, carries one of the contacts.

The cam is designed for either right- or left-hand rotation by merely turning it over on the shaft, and it has lobes to correspond to the number of sparks that the magneto is designed to deliver per revolution of the rotor. Other features are as shown. The breaker plate is set and locked by screws to the magneto bearing plate in timed relation to the magnetic break between rotor and stator of the magneto for "fixed" spark installations and to the rocking member of the magneto for variable spark ignition.

In Fig. 11 is illustrated another well-known interrupter mechanism of very novel design. This interrupter is of the rotating type. In this design the insulated contact is carried upon a spring that is secured at one end to an insulated plate. The adjustable contact is the grounded one. A triangular fibre lever that is pivoted at the center acts through one of its corners upon the cams, which force the contacts apart. The third corner is merely to balance the lever during its rotation.

In the discussion connected with Fig. 6 it was pointed out that a rocking break was very apt to be obtained in interrupters in which the contact was mounted directly upon the spring, due to a strengthening out of the spring between the points F and F_1 immediately following the application of the force F_1.

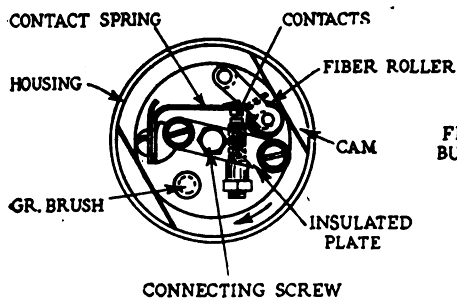

Fig. 12—A type of interrupter used in England.

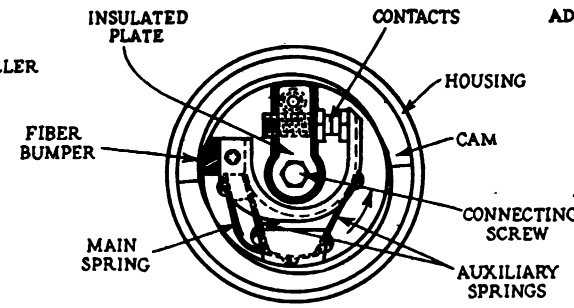

Fig. 13—A recent design of interrupter.

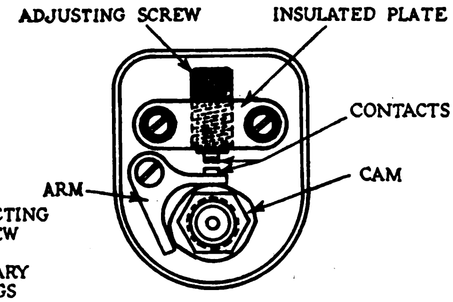

Fig. 14—A positively operated interrupter.

In this particular application of this general type of interrupter it will be noticed that the spring has a double bend between the contact point and the point at which the fibre lever acts. This stiffens the spring in the region of the bend. The tension of the spring in this case is, therefore, almost entirely on the other end of the spring, so that when the force tending to open the contacts is applied it is accomplished very effectively. The secret of the success of this particular application in avoiding the rocking of contacts is due to the bends in the spring at the places shown.

During rotation, the fibre lever is under the influence of centrifugal forces. These are intended to be balanced by the triangular shape of the lever, but the forces are allowed sufficient surplus to always keep the lever away from the spring except when in engagement with the cams.

Fig. 12 illustrates another novel design of rotating interrupter that is produced in England. In this mechanism the grounded contact is mounted directly upon the spring. The end of the spring projects considerably beyond the contact and is turned up at an angle, as shown. The insulated plate also sets at an angle to the spring, so that it and the bent end of the spring form a "V" in which a loosely bearinged roller is located. The action of the mechanism during rotation throws the in contact with the cams, which, in turn, force the roller into the "V," tending to lift the spring and its contact away from the insulated contact to break the circuit.

The liability of a rocking break of the contacts and its coincident troubles, as pointed out in connection with Fig. 6, is alleviated by the fact that the roller, which is of fibre, acts upon the spring at a point that is very close to the contact. This close application of the roller force to the contact tends to open the contacts without rocking.

Centrifugal force in this interrupter always keeps the roller as far from the center of rotation as possible, and it, therefore, can exert no force upon the contact spring until compelled to do so by the cams.

The interrupter represented in Fig. 13 is a compara- new product. It is also of the rotating type and differs from the other arm types in that it has no pivot or bearing for its arm. A main spring serves to perform the same functions of the usual interrupter arm spring; namely, to hold the contacts normally engaged. In addition, there are two auxiliary sets of leaf springs which tend to guide and support the motion of the arm. The purpose of the arrangement is not only to do away with the pivot and bearing but to give the moving contact a parallel motion with respect to the insulated contact. The advantages of this parallel motion were pointed out under the discussion of Fig. 7.

The cam in this breaker mechanism is produced by grinding two eccentric circles at 180 degrees displacement from each other and at equal distances at either side of the center of rotor motion.

The interrupter illustrated in Fig. 14, which is of the stationary type, is also comparatively new and has some very interesting and novel features. The arm is free from springs and forms a "V," in which a cam rotates and performs both the functions of closing and breaking the circuit at the contacts.

In order to take up the mechanical shock of closing and to allow for variations in production and for adjustment, the insulated contact is mounted upon a sliding plunger that is backed by a compression spring in a knurled and threaded barrel. Adjustment is made by means of this threaded barrel.

The principal advantage gained by this construction beside the simplicity of its construction, is that the time of make of the circuit is definitely determined at all times by the relation of the angle of the arm "V" and the cam lobes.

Another very interesting type of interrupter mechanism is that illustrated in Fig. 15. This type is based upon the principles discussed under Fig. 7. In this particular design it is shown for use with rotating winding types of magnetos, but the principle back of it is applicable to the stationary type of interrupter as well. The principal merits of this interrupter are the parallel motion of the separating contacts and a very quick and definite break of the circuit for a very small throw of the arm, so that the wear and the forces due to inertia to which this interrupter is subject are reduced to a minimum. The arm is also of very light construction, having, as it does, only one projecting end from the pivot, so that the forces to which the contacts are subject in closing are reduced to practically only that of the tension of the spring. Any centrifugal force at play upon the arm aids the spring.

The tendency is in this type of interrupter action for the spring to close the contacts very quickly following the separating action, so that this type of interrupter lends itself very effectively to battery and coil types of

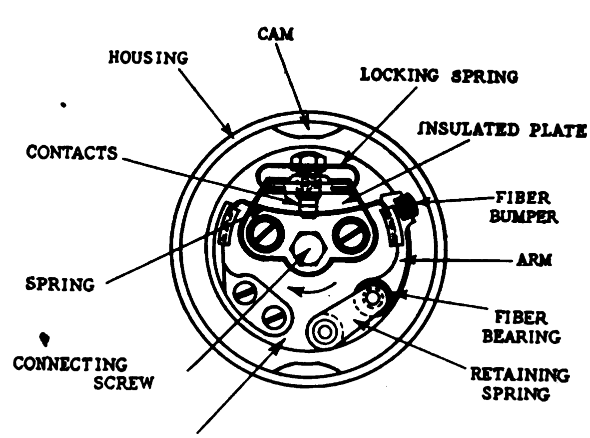

Fig. 15—A novel type of interrupter possessing many advantages.

ignition systems, because of the fact that the period necessary for the sparking action of the coils is very short and the interrupter allows a large percentage of the complete cycle of the action to be on closed circuit. This is a decided advantage in battery systems operating at high speeds.

Interrupter with Tungsten and Silver Contacts

During the war with Germany platinum supplies were limited, and ignition manufacturers did considerable experimentation with contacts made of other material. Tungsten had been used for a number of years and had given satisfactory results under special conditions. Its principal objection was that of oxidization. It has been found in rotary magneto work that tungsten will function properly as long as the magneto is in continuous operation, but if the magneto stands over night with its contacts separated the oxidization may be sufficient at times to make starting very difficult. In special cases, such as in so-called oscillating magnetos in which the normal rest position is always one in which the contacts are closed, this trouble is very much reduced, so that with tungsten comparatively cheap it made a very good substitute.

To solve this problem, in the case of rotary magnetos, a very novel interrupter was invented and developed by C. T. Mason for the Splitdorf Electrical Company. This interrupter consisted of two sets of contacts, one set acting for starting service and the second set operating for running service. The starting contacts were of silver and the running contacts were tungsten.

Fig. 16 illustrates the essential features of the design as used with magnetos having stationary coils.

The principal difference of this type of interrupter from other types is as follows: The silver contact on the grounded side is rigidly connected to the lever arm in the usual manner and it makes contact with another silver contact that is adjustably mounted in an insulated plate, to which the primary lead makes connection as in the usual construction. In addition, the lever arm carries a spring that extends parallel over the top side of the arm and terminates over a hole in the lever arm. A tungsten contact mounted upon this spring extends through the hole in the arm and engages with another tungsten contact that is also adjustably mounted in the same insulated plate with the silver contact. The tension of the tungsten contact carrying spring is such that it exerts a pressure downward. The adjustment of the interrupter contacts must be such that the silver contacts separate before the tungsten contacts do.

When the cam strikes the fibre bumper of the lever arm it first lifts the arm and therefore breaks the contact between the silver contacts. The break between the tungsten contacts occurs a very short time afterward—as soon as the bend of the contact carrying spring is taken up.

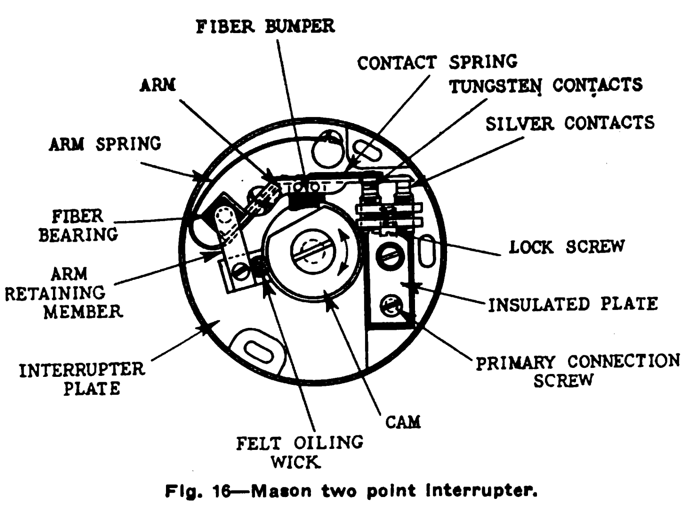

Fig. 16—Mason two point interrupter.

The result of this sequence of contact separations is such that if the tungsten contacts should be oxidized to such an extent at starting that the high resistance of the oxide makes the magneto inoperative, the completed circuit through the silver contacts which do not oxidize readily will allow the magneto to function and the spark will be produced when the silver contacts separate. The engine will therefore start up on the action of the silver contacts.

After a few revolutions of the engine the mechanical action between the tungsten contacts of the interrupter cleans them, and because of the fact that the tungsten contacts separate last, the final interruption of the circuit transfers to the tungsten contacts as soon as they begin to conduct current. It therefore follows that the tungsten contacts operate for running service.

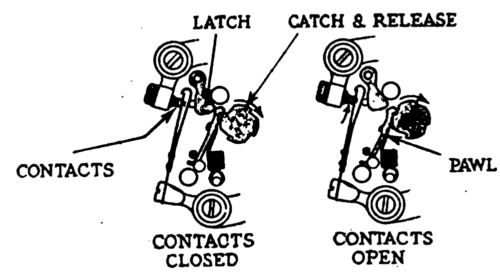

Fig. 17—The Atwater Kent interrupter.

All the arcing and welding action of service is taken up by the tungsten contacts, and the silver contacts are thus protected during the running service, and they do not function electrically again until the tungsten contacts again become inoperative except to carry a part of the primary generated current. The action of this interrupter is entirely automatic.

The only objection to this type of interrupter lies in the fact that the trade has not been educated to the adjustment of this device, and it would no doubt be considerable of a task for a layman to make the adjustments of this mechanism properly and intelligently.

The supply of platinum to ignition manufacturers was never completely cut off, hence it never became necessary to change to the double contact type. It does illustrate, however, how the tungsten contacts can be pressed into service in spite of its tendency to oxidize.

Battery and Coil System Interrupters

From the very earliest days of battery and coil ignition systems it was recognized that for ordinary make-and-break circuit interrupters the average user would very often forget to switch off the ignition circuit after stopping the engine and allow the ignition system to drain the battery during idleness of the engine if the contacts chanced to be closed.

It was also recognized that for the slower speeds of engine operation the ordinary make-and-break igniter interrupter would take a great deal more battery energy than was necessary for effective operation of the system compared with that required for running speeds.

To overcome these two drawbacks a special battery and coil ignition system interrupter was developed and marketed by the Atwater Kent Mfg. Co. This interrupter is illustrated in Fig. 17.

The illustration shows a catch and release device which, during its rotation, catches a pawl and advances it against the tension of a coil spring to a position above

a latch. After reaching this position the pawl is automatically released and is then drawn back toward its normal rest position due to the tension of the coil spring. In returning to this rest position the heel of the catch and release tooth so guides the pawl that it is compelled to strike against the latch. The motion imparted to the latch by the pawl in turn causes the contacts to close momentarily and separate again after the pawl passes the latch. This make-and-break action takes place at a very high speed, and at a speed that is independent of the speed of rotation of the catch and release member. This special type of battery and coil circuit interrupter

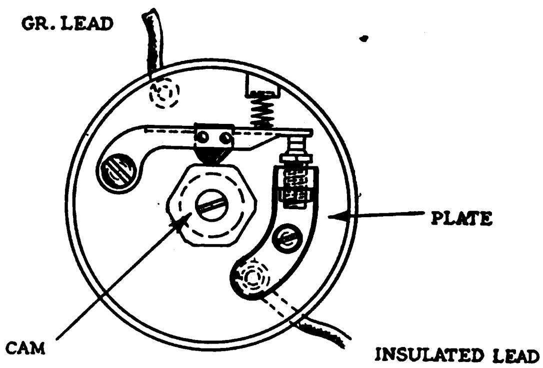

Fig. 18—Typical battery and Coil system interrupter.

therefore assures that the spark will be of the same value for all engine speeds within the limits that the device is designed for and that the battery energy required per spark will also be practically constant for all speeds.

It must also be evident that when the engine is at rest the pawl will be at rest and so cannot close the circuit, and it can never remain in a position that will keep the contacts together.

The particular mechanism shown in Fig. 17 has a catch and release with four teeth and so is designed for four-cylinder engines, being operated at half engine speed in this case. The figure shows both open and closed positions of the contacts.

Fig. 18 shows a simple battery and coil system interrupter that is representative of the more usual types. It has a six-lobe cam and is designed for a six-cylinder engine, but can be converted to a four-cylinder system by using a cam with four lobes. It is evident that in this type of mechanism it is possible for the engine to stop at such a position that the contacts will remain closed, so that this interrupter requires a switch for cutting off the battery when the system is not in use. It is also evident that the period of time allowed for the closing of the contacts depends upon the speed at which the cam rotates, so that at slower speeds more energy will be delivered to the coil for spark production than will be the case at higher speeds.

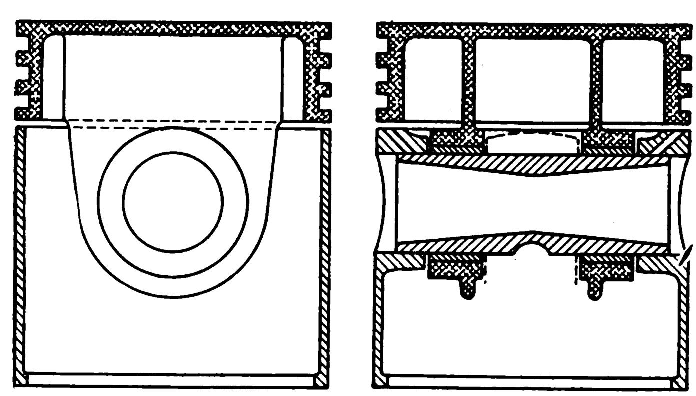
This difference in amount of battery energy consumption for different operating speeds used to be a very important consideration in the days of dry cells, but in the present time the use of storage batteries and recharging generators as part of the equipment makes this difference of battery economy of little importance. Furthermore, since the advent of high-class lock switches the user has become accustomed to switching off the battery, so that the general type of battery and coil system interrupter shown in Fig. 18 serves its purpose very well.

In the foregoing paragraphs the writer has endeavored to cover all the important interrupter considerations that have come to his observation, and, while all the different designs of interrupters now in use have not been shown, the few selected as illustrations are presented because of some very distinctive features employed to meet the conditions under which an interrupter must function.

A New Cross-Head Piston

A CROSS-HEAD type of piston designed to take advantage of the properties of both aluminum and cast iron has recently been made the subject of a patent application. The combined aluminum and iron piston is not new to the trade, but the design shown herewith includes also the cross-head characteristics, the upper part of the piston floating on the wrist pin. The piston can be fitted or adapted to the ordinary cast iron piston by cutting this off above the wrist pin and applying the aluminum upper portion. The aim in pistons of this type is to use aluminum, which has the quality of high conductivity, for the parts exposed to heat. The cast iron skirt acts as a seal and guide, and because of its lower expansion under heat, can be fitted more closely than aluminum. In this case the skirt, being insulated from heat transfer from the head, remains comparatively cool and consequently does not expand appreciably. There is a gap between the aluminum and iron portion, so that differences in expansion between the aluminum and iron make no difference in the fit or shape of the piston. This also permits of oil drainage. The bronze bushing for the wrist pin is carried in the aluminum portion of the piston, thus transmitting the explosion forces directly to the wrist pin.

This piston, which is the design of O. E. Barthel, weighs approximately the same as a light-weight, semi-steel piston.



Barthel Cross-head piston.

ONE thousand and forty-one motor cars were imported into British India during September, 1920, and of them, 723 were consigned from the United States, and 287 from the United Kingdom. During the six months, April to September, 1920, the number of motor cars imported was 7,498, as against 2,553 in the corresponding period of the previous year. The United States recorded 5,654; the United Kingdom, 1,902; Canada, 542; France, 49, and Italy, 43. Bombay imported 2,775 cars; Bengal, 2,694; Madras, 908; Sind, 590, and Burma, 531.

Lumber Used in Motor Vehicle Manufacture

Here is an interesting and informative study of the lumber consumption based on 1920 production figures. The U. S. Forest Products Laboratory prepared the statement as the result of studies made by its engineers.

By Arthur Koehler*

THE rapid increase in the proportion of closed cars manufactured is an outstanding feature of the automobile industry. An official of a large company recently expressed his belief that in five years one-half of their output would be closed cars. Already one out of every eight passenger cars of a well-known make is a sedan or coupe. This means a large consumption of lumber, as the closed car takes from two to three times as much lumber as an open car, and a better grade of lumber is required to insure rigidity and freedom from warping in the closed body.

An engineer of the United States Forest Products Laboratory, Madison, Wis., recently visited a number of manufacturing plants to determine what woods are being used in the automobile industry, to what extent substitution of one species for another is taking place and what troubles manufacturers are having with wood.

The question of what kind of lumber to use in auto bodies is becoming a perplexing one. Ash has always been considered the most desirable wood for most of the parts above the running gear. It combines the properties of moderate weight, easy workability, high degree of toughness and comparative freedom from twisting. With keen competition in the trade and the high price of ash it is gradually being replaced by other kinds of woods in order to reduce the cost of production.

No data are available showing how much lumber of each kind is used in the automobile industry. From a visit to a number of automobile and body factories the writer is inclined to believe that maple leads in the construction of passenger car bodies and elm is next and ash third. Besides these species many others are used or are being tried out. The following brief description of the more important woods used in automobile construction gives some of their relative advantages and disadvantages, and in Table 1 is given the strength of these woods as compared with forest grown ash.

Ash: The cut of ash lumber consists almost entirely of white ash, green ash and black ash. The green ash is sold as white ash and is practically identical with it in properties, but black ash is not so strong.

A number of years ago commercial white ash was the principal wood used for passenger cars, but its great demand for this purpose, airplanes, etc., brought the price up so high that substitutes are used except in some of the high priced cars which still use ash for the sills, or throughout the whole body. Because of the higher quality of closed bodies, and the necessity of avoiding warping of the parts as much as possible, ash is used by some manufacturers for closed bodies but elm for open bodies.

In Table 1 the strength of second growth white ash and of black ash are given in per cent of forest grown white ash.

*Assistant in charge, Section of Timber Physics, Forest Products Laboratory.

On account of the greater difficulty of machining maple than ash, some prefer the ash from an efficiency standpoint even though it costs a little more originally.

Much of the white ash growing in the northern states has been cut out, and over half of the supply now comes from the states bordering on the lower Mississippi River. Unfortunately, ash like other hardwoods growing in the southern swamps, produces a certain amount of light wood which is apt to be brash, especially in the swelled butts of the trees. This necessitates sorting out the material and eliminating all light pieces for purposes where strength is important.

Maple: Very little soft maple is used, nearly all of the wood which goes into bodies being hard maple. It is extensively used for sills of passenger cars. In some cars it is also used for the framework of the body and even for the floor and running boards and battery boxes.

Maple is fully as strong and stiff as a beam or post as white ash, but not as shock resisting, as is indicated in Table 1. It usually is cheaper than ash and runs more uniform in strength. Maple warps very little, in this respect being superior to elm. On the other hand, maple is more difficult to season without checking than ash or elm, and it is said not to hold screws so well in use in automobile bodies.

On account of the smooth fine texture of maple, paint and enamel will rub off more easily, especially on curved surfaces which receive considerable wear, than on birch which is slightly more porous.

Because of its smooth wearing qualities and comparative freedom from slivers maple is preferred to all other woods for the floors of delivery wagons.

TABLE 1.—STRENGTH OF WOODS USED IN AUTOMOBILE CONSTRUCTION IN PER CENT OF THE STRENGTH OF FOREST GROWN WHITE ASH*

Species	Strength as a Beam or Post	Stiffness	Shock Resisting Ability	Hardness
Hardwoods:				
Ash, white, forest grown	100.0	100.0	100.0	100.0
Ash, black	71.3	79.3	90.1	62.3
Ash, white, second growth	122.5	117.6	119.6	118.9
Basswood	59.1	80.6	40.5	29.6
Beech	93.5	96.9	96.0	90.0
Birch, yellow	104.8	116.8	120.6	80.9
Chestnut	66.0	71.9	58.4	49.2
Cottonwood	60.6	79.0	54.3	35.3
Cucumber	85.4	112.4	76.7	54.9
Elm, rock or cork	98.8	92.9	140.5	101.6
Elm, white	79.2	79.5	89.5	57.1
Gum, red	80.7	91.5	75.5	59.0
Gum, tupelo or cotton	81.4	82.5	63.5	77.3
Hickories, pecan	103.5	103.8	119.7	139.6
Hickories, true	126.6	120.2	173.9	150.4
Maple, red	90.0	101.2	78.7	75.4
Maple, silver	66.9	68.5	71.7	64.3
Maple, sugar	104.7	105.9	90.5	103.0
Oaks, all kinds	92.6	101.3	94.9	104.5
Poplar, yellow	67.3	93.8	41.5	37.9
Conifers:				
Firs, Douglas, Pacific Coast type	95.7	122.1	59.9	58.3
Pine, loblolly	93.7	105.6	71.0	60.0
Pine, longleaf	112.2	122.1	77.7	74.8
Pine, shortleaf	94.1	100.6	69.7	64.0
Pine, western, white	75.5	99.7	53.8	37.0
Pine, western, yellow	67.0	75.6	42.9	41.0
Spruce, Sitka	69.5	94.1	63.3	44.9

*For information on actual strength values of these and other species see United States Department of Agriculture Bulletin No. 556, "Mechanical Properties of Woods Grown in the United States."

Elm: Soft or white elm is the principal species of elm used in automobile manufacture. A little rock elm is used for some of the bent parts, but otherwise white elm is preferred because it is more easily worked and is less subject to warping. Lumber from old white elm trees, usually called "grey elm," is preferred to that from younger, or vigorously growing trees, because it is more easily worked and gives less trouble in seasoning and manufacture because it warps less.

The principal use of elm is for frames, seat backs and doors; very little, if any, is used for sills. Old white elm is not so strong or tough as ash on the average, but it varies less in strength than ash, especially that which comes from the southern swamps.

Birch: Yellow birch is used considerably in automobile manufacture and is a close rival of maple. It is used for sills, framework and other minor parts. It is preferred to maple on exposed painted parts because it is said to hold the paint better. Its use probably is increasing.

Hickory: The use of hickory in automobile manufacture is confined almost exclusively to the spokes and felloes. In recent years the wooden felloe in automobile wheels has been replaced to a large extent by a steel rim into which the ends of the spokes fit. If this substitution proves satisfactory it will be of decided economic significance, since it will leave a large amount of hickory for the manufacture of handles for which there is no satisfactory substitute. The present trend toward the all metal wheel already eliminates thousands of hickory spokes, but it is too early to say how far this substitution may be expected to go. There is a certain resiliency in the hickory spoke which is not easily duplicated with other materials.

No distinction is made between the true hickories, such as shagbark, big shell bark, mockernut, and pignut, but the pecan hickories, such as pecan, bitternut, nutmeg and water hickory are, as a class, inferior in strength to the true hickories, especially in shock resisting ability. The pecan hickories might be used in place of ash, elm, birch or maple in the body, although their hardness and tendency to twist might prove a serious drawback to such uses.

Red Gum: This species name includes both the sapwood and heartwood. It is used for floor boards, seat risers, seat boards and other minor parts, but it is too weak and soft for the sills or other major parts of the frame. One of the principal drawbacks to the use of gum is its tendency to warp when used in places where it is subject to changes in moisture content. Quarter sawed gum boards give less trouble in warping than plain sawed boards.

Oak: In automobile construction no distinction is made, as a rule, between the different species of oak or even between the red oak and white oak groups. In passenger cars oak is rarely used for the frame or sills. Wormy oak is used for running boards, floor boards and seats. Some sound oak is used for instrument boards and battery boxes.

Top bows are made almost exclusively of oak, second growth being preferred.

In trucks, on the other hand, oak is one of the leading woods. It is used for sills, cross sills, frame of body, floor and stakes.

In Table 1 all the oaks in which tests have been made are grouped together under one name.

Southern Yellow Pine: Under this heading are included longleaf, loblolly, shortleaf, and some of the minor southern pines. The use of yellow pine in automobile manufacture probably is increasing. It is used for running boards, floor boards, seat boards and a number of small parts in the seats and frames.

Other Species Used: The above descriptions cover the principal woods used in passenger and freight automobiles. Numerous other species are used to a limited extent. Cottonwood is used for dash boards of passenger cars and the boxes or bodies of trucks. Sycamore, beech, basswood, yellow poplar, cucumber, tupelo, gum, chestnut, Douglas fir, western yellow pine and possibly other woods have been used in small quantities.

In addition to these, fancy woods, such as walnut, cherry, mahogany, rosewood, tulip wood, etc., are used for trim in high priced cars.

Table 2 shows the kinds of wood used in the different parts of an automobile, based on a study of those companies which made bodies for a number of automobile manufacturers.

Table 2—Kinds of Wood Used in Open Cars

Sills, longitudinal and cross—Ash, hard maple, and occasionally elm, red gum, magnolia and soft maple.
Floor boards—Sound and wormy oak, hard and soft maple, red gum, beech, wormy chestnut, elm.
Seat risers, or "heel boards"—Hard and soft maple, red gum, yellow pine.
Seat boards, or seat frame—Hard and soft maple, red gum and numerous other species.
Seat lids—Maple, gum, elm and numerous other species of plywood.
Pillars and posts—Hard and soft maple, ash, elm, sycamore and red gum.
Seat rails (arm and back)—Ash, elm and maple.
Strainer slats, or "spring slats"—Maple, ash and gum.
Doors—Hard and soft maple, ash and elm.
Trim rails—Rock elm.
Running boards—Wormy oak, yellow pine, maple, Douglas fir.
Steering wheels—Walnut, maple, red gum.
Spokes—Hickory.
Rims ("felloes")—Hickory.
Top bows—Oak.
Dash—Cottonwood and maple.

It is estimated by the Forest Products Laboratory that the total amount of wood used in the construction of automobiles and motor trucks in the United States amounted to 384,751,000 ft. b.m. in the year 1919. The total consumption of wood used in the industry is roughly estimated in the accompanying Table 3.

Table 3—Amount of Lumber Used Annually in the Manufacture and Shipment of Passenger Cars and Motor Trucks, Based on 1919 Production of Cars

Total output of passenger cars	1,883,158	
Average number of board feet of lumber used per car	160	
Total lumber used in passenger cars		301,305,280 bd. ft.
Total output of motor trucks..	322,039	
Average number of board feet of lumber used per truck, including body	200	
Total lumber used in motor trucks		64,407,800 bd. ft.
Total number of passenger cars exported	141,477	
Average number of board feet of lumber used in export crating of passenger cars...	660	
Total lumber used in export crating of passenger cars		93,374,870 bd. ft.

Total number of trucks exported	29,288
Average number of board feet of lumber used in export crating of trucks	760
Total lumber used in export crating of motor trucks	22,458,880 bd. ft.
Grand total	481,546,780 bd. ft.

Computation on basis of 1920 figures made by AUTOMOTIVE INDUSTRIES.

The amount of lumber used in each car varies from 75 ft. b.m. for a small open car to 200 ft. b.m. for a medium-priced touring car. An average given by a large body manufacturing corporation is 140 to 150 ft. b.m. for open cars for each body. A small sedan requires 225 ft. b.m. and a large sedan, not including running boards, uses about 310 ft. b.m. One company stated that the average waste was about 30 per cent, including drying losses, cutting and minimum jointer waste, although others place the waste as high as 40 per cent.

In automobile work, first and seconds are used nearly exclusively. One company used 75 per cent first and seconds and 25 per cent No. 1 common. A large body company used 40 to 50 per cent first and seconds, and the rest No. 1 common of maple, elm, and oak. Another company making high-priced cars will take only 20 per cent of No. 1 common.

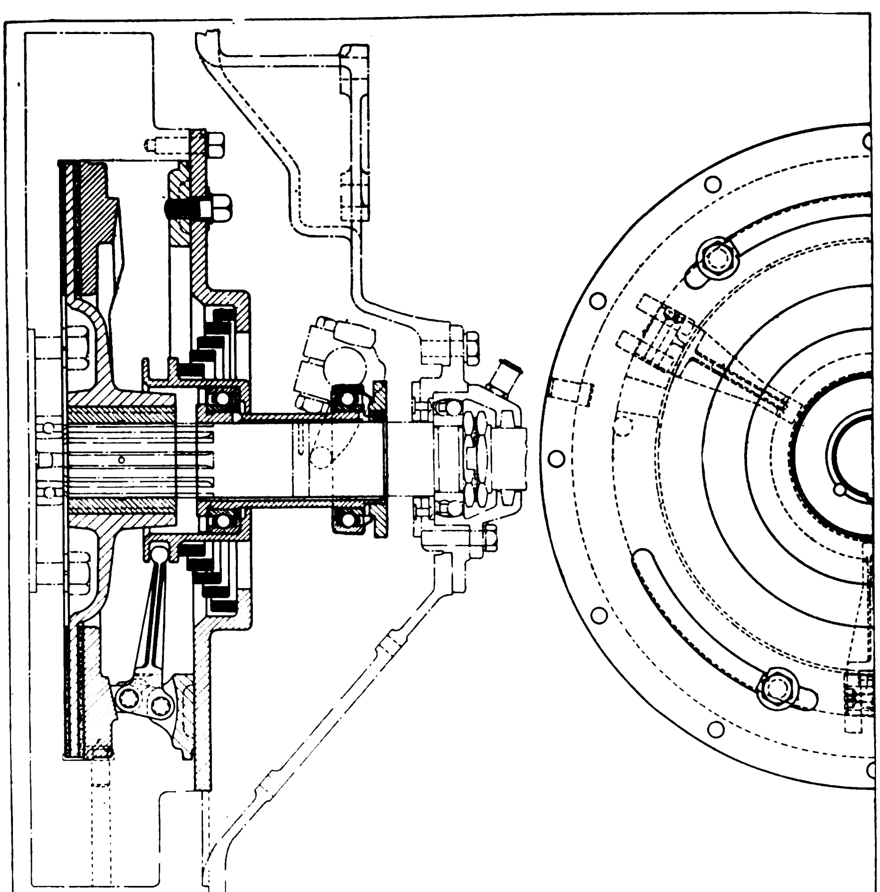
A Heavy Duty Single Plate Clutch

A NEW 14-in. heavy-duty clutch has been placed on the market to meet a demand for a single plate clutch which will satisfactorily transmit a torque of as high as 350 lb.-feet. This clutch is intended especially for tractor and heavy-truck service. The area of the friction surface is 100 sq. in. and the unit pressure on this surface approximates 30 lb. per sq. in. The friction mats are of a type recently developed for the Borg & Beck clutch and are said to have shown satisfactory results even with a unit pressure of 60 lb.

The drive is transmitted from the friction disk to the shaft through a 1¾-in. diameter 10 spline S. A. E. standard fitting, the length of this fitting being 2½ in. Lubrication of the splines is provided for by turning a groove centrally in the bore of the friction disk, slightly larger in diameter than the top diameter of the splines. This groove communicates, by means of radial holes in the shaft, with an axial hole extending the entire length of the shaft, so that when this hole is fed grease either from a compression cup or grease gun, the pilot bearing, splines and thrust bearings are simultaneously lubricated.

The thrust bearings are alloy steel, heat treated and ground to close tolerances. These bearings are claimed to possess advantages in respect to efficient lubrication, quiet operation and ability to withstand constant use.

Three adjustment screws pass through the cover of the clutch, and each screw has only one repeat hole, spaced equi-distant from the bell crank, so that the mounting ring is always held rigidly to the cover, thus eliminating any tendency of the ring to spring and cause drag when the clutch is released. This clutch is known as type F.J.X. and is manufactured by the Borg & Beck Co.



Model F.J.X. Borg and Beck heavy duty single plate clutch.

Chemistry of the Earth's Crust

ASSUMING the earth's crust to be a layer about 10 miles deep, Henry S. Washington of the Geophysical Laboratory, writing in the Journal of the Franklin Institute, estimates that 95 per cent of the crust is made up of igneous rocks, mainly silicates of Al, Fe, Mg, Ca, Na, K. Silica itself represents nearly 60 per cent of his mass of the crust. His percentages are in round numbers: Oxygen, 46; silicon, 28; aluminum, 8; iron, 5; calcium, 3.6; sodium, 2.8; potassium, 2.6; magnesium, 2.1. All the other elements are calculated to be present in less than 1 per cent each: titanium and phosphorus, each, 0.13; hydrogen, 0.127; manganese, 0.01, etc., and in order fluorine, chlorine, sulphur, etc., with bromine, tellurium and platinum at the end of the series. The first-mentioned elements down to manganese are supposed to make up 99.6 per cent of the crust, while the interior of the earth would, it is concluded, consist largely of magnetic nickel-iron. These estimates are based upon varied considerations and upon the analyses of some 5000 rocks.

Factory Service Relations with Dealers

The part played by the engineering department in regard to defective parts was one topic discussed at a recent convention of factory service managers. The dealer is now in the position of a buyer in a buyers' market and seems to be getting more consideration than heretofore. Parts prices and return of parts to factory for credit discussed.

By J. Howard Pile*

THE outstanding feature of the convention of Factory Service Managers, held under the auspices of the National Automobile Chamber of Commerce at the Hotel Iroquois, May 16, 17 and 18, was the changed attitude of the factory toward the dealer and distributor. In past conventions of this kind there has been a dictatorial attitude, and the theme of the papers and discussions has been what the factory shall "allow" the dealer. With the factories now seeking to sell more cars, and the dealer in the advantageous position of a buyer in a buyers' market, these things have changed and many agreements and practices to the advantage of the dealer are approved which six months ago would have been turned down flat.

The attitude of some of the factory managers toward parts prices was somewhat disappointing. While owners have been looking for more satisfactory prices on service work, and dealers and distributors have, in many cases, devoted much thought and time to the development of service stations that could render more economical service, the attitude of some of the factories seems to be to put as much on parts prices as the traffic will stand. While the prices of the parts may not seem so high according to lists, there are transportation charges, handling charges and taxes which have to be undertaken by the purchaser, and several suggestions that parts price lists to the car owner be discontinued, so that he would not know how much he was going to have to pay, seemed to meet with approval, although some objected.

The relation of the engineering and service departments of the factory was discussed at some length, following papers by Bachman of Autocar and Rippingill of Hudson. The point of contact between these two departments is in the return of defective parts to the factory. In some factories the practice is for the engineering department to pass on credit for these parts, the idea being that the engineering department thereby will see what parts are falling down and will be able to redesign where necessary. As a matter of fact, it would seem that ordinary defective parts can be just as well decided on either by the factory service department or the local service department with quicker action, which would result in benefit to the owner. Reports could be made out on these ordinary defective parts and turned over to the engineering department. Any extraordinary defective part could, of course, be returned to the engineering department for personal inspection. Very few factories require all parts to be returned to the factory before credit will be granted, but most every factory requires that certain classes of defectives be returned. It was suggested at one point that all service departments should be self-supporting, and this view was very vigorously attacked by Chairman Cummer of Autocar, who stated that he felt that the service department was not a profit-making department and was in the same class with advertising, auditing, etc., which departments, while they produce good and assist in the sales of the cars, cannot be expected to pay their own expenses or even a portion. This frank statement was very generally approved of.

There seems to be a tendency on the part of dealers at the present time to return parts to the factory for credit. This situation has been brought about by unwise orders placed during times when stocks were scarce at the factory, and dealers are now seeking in many cases to reduce their inventory. The remedy for this would seem to be to place a charge of 10 per cent on all material returned for credit, with the exception of parts made obsolete by new designs. Current parts should be checked up pretty carefully to prevent dealers from cutting their stocks down below the minimum required amount. The deterioration of equipment on cars which have been in stock for from five to six months was brought up for discussion, and H. Barcroft White, a dealer in Syracuse, suggested that manufacturers get together and handle this situation along safe and sane lines. A discussion of topics covering transportation charges on parts to dealers at distant points brought up the advisability of furnishing the owner with a printed price list of parts. Inasmuch as some factories allow the dealer to charge the owner transportation charges and sometimes handling charges, it was felt that the owner would have a legitimate kick if he found the prices actually charged, including all these items, was very greatly in excess of the printed list gotten out by the factory. It developed that a good many factories did not furnish such lists to car owners.

Who's Got the Button?

Editor AUTOMOTIVE INDUSTRIES:

I would like to have the addresses of the company building the highest type of four-cylinder, high efficiency motors. This company is planning a new type of high efficiency four-cylinder motor car and wishes to obtain the very best engine that it is possible to obtain. Only the superlative product will meet the requirements.

FINN S. HUDSON, U. S. Products Corp.

An Experience in Foreign Automobile Advertising

One of the very interesting points about this paper is that it applies so directly to domestic advertising. The big factor appears to be to decide on an objective, then on a method, sticking as closely as possible to both.

By Frederick Dickinson*

THE company which I represent entered the field of foreign advertising, as a great many companies in the early days entered it, at the point of least resistance. Within two years of our establishment we had secured a good, strong foothold abroad, largely through the efficacy of a rather daring and remarkable piece of "stunt" publicity. Within a very short time after that we had established ourselves rather firmly, because of the timeliness of our entry and the peculiar adaptability of our product to the foreign demand.

Advertising, in a formal sense, played a very small part at the beginning of our export merchandising. It is amusing to look back at those early days and note that out of the mass of formal advertising which grew out of our entry into the foreign field, the bulk of it was used in this country to establish ourselves in the domestic field. It apparently never occurred to us that information concerning our remarkable world tour could be disseminated through the export publicity media in such a way as to develop our export market. We used this information right at home, and profited by it greatly. But that, speaking generally, was as far as it went. The reason for this was our complete ignorance, even after a couple of years of export merchandising, of the ways and means by which export advertising, in a formal sense, is accomplished.

That ignorance, by the way, exists to-day in the minds of many organizations selling in the foreign field, and I am frank to say that after all of these years, and after considerable study and marked improvement, our organization has not entirely solved the export advertising problem. Hence the necessity and the desirability of such discussions as these in which we are now taking part.

But to go back: Circumstances were considerably kinder to us than we were to ourselves. In spite of our almost criminal ignorance of how it could be developed by advertising, our foreign demand increased. The impetus given it by our dramatic entry had not died out, and it was further stimulated by what was practically a repetition of the original stunt.

Again, I must confess that that repetition was undertaken largely to furnish material for domestic use. It seems unbelievable, doesn't it, that intelligent men could be so blind as not to realize the possibilities of what they were doing for use in one field, and so keenly conscious of its use in another field? But, again, I must give as an excuse the seemingly impenetrable darkness which surrounded formal foreign advertising.

Speaking from the standpoint of an advertising man, we did not deserve the success we secured; but nevertheless success was ours. Our distributors dotted the globe, and they were selling all of our product that we could, or thought we could, afford to give them.

Then, one by one, these distributors, in a very limited and groping way, began to advertise. In those days they advertised, I sincerely believe, not because they needed it, and not because they had a complete realization of what advertising could do for them, but because it seemed the natural and expected procedure for a man in business to spend a certain sum, very indefinite in amount, and very haphazard as to method, in advertising. A great many people, at home and abroad, are still advertising in this manner. They literally know not what they do, or why they do it. It is part of the game, just as the chiropodists, twenty years ago, all wore high hats, and the undertakers to-day all wear frock coats.

But as the years went by, this natural and necessary burden of advertising increased. The publications which profited by it kept pushing our distributors farther and farther along, and tempting them to more expensive efforts. Competition entered, and increased. Our distributors, with a vague conception of the possible good that might come from advertising, increased their own advertising burden to the point where they began to look around for some one to help them carry it. They naturally looked in our direction.

This marked the beginning, with our company, of the division of expense between the factory and the distributor on advertising bills, on the basis of a certain definite amount per car shipped, as the factory share. The distributor wrote his own advertising copy, selected his own advertising media, and determined the size and extent of his schedule.

Having entered upon this arrangement, it was continued for a number of years, and it is entirely to the purpose of my address to-day to tell you that on the whole it was a very unsatisfactory arrangement, and to tell you why.

I am not saying that it could not have been made satisfactory or that all similar arrangements have proved, and are still proving, unsatisfactory to other organizations. If I am to preserve the integrity of my remarks in a way that will make them, in the slightest degree, helpful to you, I cannot go beyond our own experience.

As to copy and the things that were printed in public regarding our product, we were at the mercy of about eighty separate individuals; practically all of them untrained as writers of advertising, many of them unacquainted with our product except in a most limited sense, most of them, because of distance and widely varying environments, unable to grasp our ideas and ideals. This condition made not only for inefficacious and useless copy, but for actually dangerous copy. Statements were made,

*Advertising Manager Hupp Motor Car Co. Paper presented at the Eighth Annual Foreign Trade Convention.

if not literally over our name, virtually with our sanction, that we could not substantiate. Misstatements were many, exaggerations the rule. In those countries where the precept "Let the buyer beware" still held sway, representations were made that got us into trouble. I recall one instance in particular where our product was advertised as "guaranteed for life." The ambiguous nature of that guarantee, interpreted according to our ideals, cost us money.

The question might be asked at this point: "Why didn't you furnish your own copy, thus helping the dealer out, and preventing unpleasant complications?" We did that very thing, but our distributors still had their own ideas. It wasn't strong enough for them. Some of them *wanted* to exaggerate and distort. It did not contain that evanescent "something," the absence of which even a child can detect, but the presence of which no one seems to recognize—local color. Many of them were willing to use our copy but no two of them wanted the same kind of copy. We were placed in the position of writing special stuff for every important country in the world, and submitting it to a captious critic in every one of them.

"Why, then, did you not force the issue, and refuse to participate in the expense of advertising of which you did not approve?" We did that, too; and became involved in endless disputes. We were pitted against four score "fathers," each fighting for his advertising child; and, what was more important, fighting for hard cash in the shape of an advertising allowance. Now, an endless dispute, carried on across a hemisphere, with a man who does not speak or write your language, is a difficult and unpleasant thing. Distributors were alienated. The friction arising from advertising controversies interfered with sales and service. We found ourselves giving in where we should not have given in, simply for the sake of preserving an important connection. Thus bad precedents crept in. Money was allotted for advertising that never found its way into advertising channels. A bad way of doing business, you will say, but I will defy any one with as much at stake as we had, to have done differently.

I have dwelt at some length on the matter of copy, in order that I may save time on some of the other factors. The difficulties that arose around copy typify, in a measure, the difficulties that arose around the selection of media, and the size and extent of schedules.

Theoretically, a man doing business in Australia should know what Australian advertising media to use for his advertising. Actually, that man knows no such thing, unless he is an advertising man. The same thing, by the way, holds true in this country. Our distributors by and large were not advertising men. They selected publications because they themselves read those publications, or because their friends read them, or because their wife's uncle owned them, or because the publisher was a good fellow, or because the business manager would give them a rake-off, or because their solicitor happened to drop in at the time the advertising was being placed. We found our advertising appearing in media that would not sell a car for us in a thousand years. Many distributors displayed a fondness for advertising in their own trade publications, read only by men selling the kind of things that they themselves had to sell—dealers advertising to each other, in other words. Dealers would select an absolutely worthless medium, whose circulation was confined to their own territories, and pass up an excellent medium that would actually sell cars for them, because part of that medium's circulation was in another dealer's territory. Shortsightedness, ignorance, and lack of experience controlled our list.

And the disputes and misunderstandings that arose over copy were duplicated and aggravated by the disputes that arose over media.

The differences of opinion that arose as to size and extent of campaigns were not as numerous and serious as were the other bones of contention. Nevertheless, in this respect, and in many places, conditions were not altogether satisfactory. Although we made a certain allowance per car, the amount was intended as a limit, and not as a definite recommendation. Hence, we found some distributors wasting their own money, and ours as well, simply for the purpose of absorbing the maximum allowance. One-half the amount, or two-thirds, would have been adequate. As in the case of a distributor who had a limited territory, a fairly active market, and only one inexpensive publication covering the entire market, we would find that distributor blossoming out into full page schedules, where half the space would have accomplished the maximum results.

My enumeration thus far has included only what I will call, for lack of a better phrase, the basic difficulties of our advertising arrangement at that time. There were many other accessory and supplementary difficulties. In order that our plan might work with some degree of system, and be not altogether haphazard and inefficient, a considerable amount of checking had to be done. Hence this rule: that a distributor, in order to receive his advertising allowance, must submit to us monthly clippings of his advertising, accompanied by receipted bills for the payment thereof. Hardly any distributor, it seemed to us, even after months of education and stimulation, seemed able to comply with these simple requirements. Entire campaigns would be represented by a few scattered clippings. Clippings came without receipted bills; some without bills at all. Clippings would not correspond in size with the lineage shown on the bills. Additions and extensions were wrong. Rates fluctuated, even in the course of a short campaign. Repeated urgings and warnings failed to secure monthly or regular submission of these claims; and they would all come piling in at the end of the year, or the middle of the year following their appearance. We, on our end, occasionally made mistakes; credits that should have been passed, were not passed, or the amount was incorrect. All of this entailed endless correspondence, and an increasing burden of misunderstanding and suspicion, and a decreasing amount of actual advertising efficiency.

After convincing ourselves that this particular method of handling foreign advertising was not working out in our particular case, we decided to make a radical change. We inaugurated an entirely different system—the system under which we are now working. That system is not perfect, either in itself or in our application of it, but it is at least, to our way of thinking, a decided advance over its predecessor. Again, let me say that my implied condemnation of the older plan simply applies to our experience. We could not make a "go" of it. Possibly others smarter than we can do it. It has points in its favor.

Some three or four years ago, we announced to all of our foreign distributors that at the expiration of the current season no further advertising allowances were to be made. We told them that from then on we proposed to handle our export advertising in much the same manner as we were handling our domestic advertising. We would make up a list of publications having circulation in the territories of our export distributors, and would run in those publications a consistent advertising campaign composed of advertising which we prepared ourselves. We carefully explained to them our reasons for the change, which were, briefly, as follows: We wanted to be sure that our story was being told regularly and steadily throughout our market, and told in our own words. We wanted to guard ourselves against misstatement, exaggeration, and insuffi-

ciency of statement. We were going to pay the entire cost of this venture ourselves. It was probably the significance of this last statement that smothered the fury of the reaction which we expected. Only those distributors who were obviously misusing and diverting our advertising allowance made any great protest.

So we started in, with all of the resources and ability and ingenuity at our command. We made many mistakes —some of them as ludicrous as had ever been made by our distributors. But our mistakes were not perpetuated, because we had it completely in our power to rectify these errors as fast as they were discovered. We had no differences of opinion to iron out, no long-winded and long-distance correspondence to conduct. We were treading on no one's toes and wounding no one's sensibilities.

We are still handling our foreign advertising after this manner, and we are still making mistakes, and still, in some instances, wasting money. But these mistakes and these wastes are decreasing. On the whole, every one concerned is as satisfied as one could expect a large and scattered and heterogeneous group to be.

Before going on to more discussion of our methods and experience, and the points of general information that have arisen out of them, let me say that in a few scattered instances, where circumstances seem to warrant it, we are still continuing our allowance system. These places are so few that we are able to keep them entirely under our direction and control.

Our change of plan brought with it very many problems, the discussion of which I hope will throw some light on everybody's foreign advertising problems.

First came the handling of the machinery and routine connected with an activity of this size. We decided that this could best be handled by an agency—certainly an agency acquainted with the foreign field and having established relations with the publications and having knowledge of conditions in that field, and preferably an agency located in this country.

We had many bids for our business from agencies located abroad, but we could not see where an agency located in a foreign country, when it came to placing advertising outside of that country's boundaries, would have any advantage over a similar agency located in the United States. We were not established to conduct negotiations with agencies located in each country in which we did business. We felt that the complications involved in those dealings would be equal to the complications formerly involved in dealing with each of our distributors. The responsibility would be too much divided. In many countries, of course, no reputable agencies were available. So to an agency located in this country, and familiar from long experience with the foreign field, we turned over the burden of our routine.

The next problem was the compilation of a list. For the sake of saving time and getting started, our first list was largely the work of our agency; but no sooner was advertising started in that list than we began to check up on its individual units, through our distributors, through our foreign travelers, and through all other sources of information at our command. Little by little, and here and there, it was changed—in some places expanded, in others contracted, in still other places wholesale substitutions were made.

In making such adjustments, this has been our procedure: Whenever a doubt has arisen as to the availability of a certain publication, or group of publications, for our purpose, we have gathered together from all of our sources of information, both friendly and unfriendly, all the facts that we could muster; and we have decided the issue on the weight of evidence, combined with our conception of the job we were trying to do. This process will continue, I expect, as long as we are doing foreign advertising. For conditions are constantly changing; the fortunes of various publications are constantly rising and falling; our individual problems are by no means fixed. So much for our list and its history from the beginning to the present.

Copy was the next nut to be cracked. On the question of foreign advertising copy there were, and are, as many opinions as there are individuals engaged in the production of it—plus, I might say, as many individuals as there are engaged in reading it or hearing about it. (This is equally true of domestic copy, and equally true, I believe, of all phases of advertising practice. But I don't want to get off the track on that subject.)

We attacked our copy problem, and are still attacking it, from three different angles.

FIRST: What specific purpose were we trying to accomplish aside from the general purpose—which is the general purpose of all advertising—of selling our product?

SECOND: Placing ourselves in the position of the people who were to read our advertising—half informed or misinformed or totally uninformed—what did our common sense tell us should be said in order to accomplish our immediate purpose?

THIRD: How near to, or how far from, accomplishing our purpose had the independent advertising of our distributors come, and in what way had they registered success or failure?

The first point was easy. The success of all of our advertising effort (and we have been successful, I believe, in that respect) has depended on our ability to establish for our product a certain definite reputation. I will not go into a discussion of the right or wrong of our opinions on that subject, or of the technique involved, because it is a big subject and takes us far away from the purpose of this meeting. But, assuming that our ideas on the subject of advertising copy in general were right, we could see no reason why the immediate purpose of our foreign advertising should differ from the immediate purpose of our domestic advertising.

The disposal of the second point was not so easy. There were so many things that could be talked about, and so many ways of talking about each one of them, that, with the limitations of a moderately sized advertisement and a moderately sized campaign staring us in the face, the decision of what to include and what to discard was a hard one to make. We finally decided that our campaigns should be limited to very brief, simple statements concerning these three things:

1. Brief cataloging of our product—just enough to pretty definitely locate it as to general type and position in respect to other similar products. For example, to explain what I mean, we wanted them to know it was a four-cylinder car, of a certain size, made in certain models, and with certain equipment.

2. A modest statement of those qualities which gave our product a certain reputation.

3. With an eye to establishing or promoting confidence, an indication of the age, size and reputation of our company.

Opinions may differ regarding the wisdom of our confining ourselves to these points, but nevertheless we have so confined ourselves, and the results seem to justify our decision.

Quite regardless of its merits from a propaganda standpoint, the simplicity of our copy plan commended itself from a purely practical standpoint. In the first place, it permitted considerable condensation where only limited

space was available. It was not so complicated but what it could be embodied in the kind of simple, direct phraseology that was most likely to be comprehended by the average reader. It contained the minimum of possible complications when the question of translation came up. Let me say that our copy plan, also, has undergone changes and modifications from time to time. The general idea, however, has always remained the same.

With the list and the copy out of the way, the size and extent of the campaign came up for consideration. In this, too, our decision was based on our practice in domestic advertising. We have always been believers in regular and continuous advertising, as opposed to variable and irregular advertising. Our foreign campaigns have always been consistent and regular. We have taken the amount of money available for advertising in any given country, and spent it in the largest, consistent, regular campaign that it would buy; the amount of money available limiting the maximum size of space; common sense and the determination of what was necessary to command attention limiting the minimum size of space. For example, generally speaking, we prefer twelve half pages in a monthly publication to six full pages. This is not an entirely good example, because other considerations might affect our procedure; but I am sure that you get the idea.

So much for the fundamentals of our present plan of foreign advertising, and what preceded and led up to it. But there are other little side issues that are almost as important as the fundamentals themselves. Take the matter of what constitutes eligibility in a publication for inclusion in our list. We have found that, considering the limits of a modest appropriation, the best results are obtained from publications of general circulation, locating their circulation, insofar as may be, among the classes most likely to purchase our goods. This is in the nature of advertising first principles, and requires no elaboration. Where general publications of proper character are not available, we are driven to something more local. We have no objection to the more localized publication, such as newspapers, except that the use of them usually involves the expenditure of a great deal more money than is available. More of them have to be used. While they may carry our message closer home, and spread it more thickly, we cannot afford, nor do we need, in normal times, to cultivate our foreign market thus intensively and extensively.

It must be borne in mind that we are not producing goods exclusively for the foreign market. A certain volume must of necessity be maintained at home. The intensity of our foreign merchandising must be determined by the quantity of our goods that we decide to allot to the foreign field.

I will admit that at present, along with most every one else, we could allot to the foreign field much more of our product than they are taking; but I am speaking of normal times under normal conditions.

A foreign advertising appropriation is not an easy thing to determine. We are not entirely satisfied with our method; but this is it. We base our total advertising appropriation, domestic and foreign, on the amount of goods we plan to produce in a given year, influenced and modified by the amount of sales resistance we expect to encounter, and we allot to the foreign field, generally speaking, an amount in proportion to the number of units we plan to sell abroad.

There is one question which may be in the minds of some of you, the answer to which I did not consider in its proper place because it seemed to break the continuity of the discussion, and that is this: "Are you not, by financing your big foreign advertising campaign out of your own pocket, encouraging your foreign distributors to lie down on their end of the merchandising job?" We are, unless steps are being taken to counteract the influence. Those steps are being taken.

We are telling our foreign distributors that our advertising in their respective territories is in the nature of general reputation-building propaganda, such as we carry on in this country in our magazines of general circulation; and that they, too, like our domestic distributors, must see to it that their immediate local markets do not remain uncultivated. We are suggesting, and that suggestion is rapidly developing into a demand, that they spend in their territory a sum equal, if not greater, than we spend in that same territory.

While our advertising is opening up and developing their market in a broad, general way, their advertising should be cultivating and re-cultivating that same market. We are meeting with a marked degree of success, and I predict that when things open up again abroad in a big way, we shall be able to do infinitely more than we have done in this respect.

In conclusion, let me offer this apology, if such an apology is necessary. The purpose of the addresses and discussion at this convention is to promote the dissemination of general information—the kind of information that can be assimilated and used by concerns marketing widely differing products under widely differing conditions. In the light of this, it may seem as though my discussion were too closely confined to personal experiences, in a particular line of merchandising. But, after all, what real information can one man give to another man except information gathered from his own experience? All other kinds of general information can be gathered from books, and reports, and the experiences of other men. The only thing that an individual has that is really his own, is his own reactions and conclusions, based upon his own experience. If his reactions and conclusions differ in no way from those of other men undergoing similar experiences, he can at least throw them in to swell the average and help establish a rule. If they differ in some respects, they should be, in that degree at least, informative. Although my experience has been largely a specialized one, I have tried to draw from it only those conclusions that seem to me in some way pertinent to the subject of foreign advertising in general.

One more word: There are many stages in the process of development which I have described, that from necessity had to be omitted. There are kinks and angles of our present plan that could not be included for the same reasons. If you can think of any of these, and if the brief discussion of them will be interesting to you, I hope you will not fail to bring them up in the general discussion which is to follow.

British Motorcycle Registrations

JUDGING on the basis of figures available at present, it would seem that the United States has a considerably larger number of motorcycles in use than Great Britain. Under the new British registration law it will be possible for the first time to determine exactly the number of motorcycles and automobiles in use in the British Isles. There have been 186,000 motorcycles registered up to March 1, while authoritative estimates place the total which will be reached when all the machines get on the road for the year at about 200,000.

This is considerably below the American registration of last year, which was 234,000. In this country, moreover, there are undoubtedly many thousands of motorcycles which are never officially registered.

The Possibility of Developing Leaders

The older leaders received their business education when business was small and when rules and regulations were few. Present methods tend to remove from the individual the necessity for judgment. Consequently competent leaders are not being developed as rapidly as they are needed.

By Harry Tipper

FROM time to time we have considered the question of standardized method of dealing with human relations in industry, the adoption of many rules of selection, examination and training, and the danger of uniformity. The matter cannot be stressed too strongly.

Year after year in my lecture work at the New York University some student has asked continually for a rule governing this point in human action or that point. He is not willing to spend the time and labor necessary to discover the fundamentals, digest and understand the principles. What he wants is an educational pill which will work while his intellect sleeps, and give him a solution of the problem.

The biggest job for the man who lectures to such young men is the job of awakening the mind to thought, so that it will get some measure of understanding. In human affairs there is no uniform problem. There is an infinite variation in the individual quality, action and expressed capacity.

The individual differences and the friction of activity arising from the differences are the bases of improvement. We have already molded men's work by system, rule and regulation to the point where there exists an undesirable uniformity in their surroundings. In the minds of many men who are concerned with industrial relations, either in industry or out of industry, the idea of further uniformity, miscalled standardization, is the ideal toward which they strive.

Until we are clearly informed as to the principles upon which human action depends we cannot standardize, because such principles themselves are the only standards by which a measure can be made.

The laws of physics are the basis for all mechanical calculations, and out of them grow the other formulæ with which we shorten the time of our calculations and improve the quantity of work. Without a knowledge of these laws the formulæ themselves would be impossible.

So-called standards of examination for quality, fitness for work and character reading are entirely arbitrary and simply relieve the man who is charged with the responsibility from the amount of study and labor necessary to a proper examination of the individual. Obviously they cannot take count of the infinite variety and the effect which this variation has upon the individual quality and capacity. Skill can be measured because of its tangible result. Quality, character and capacity cannot be measured because the fundamentals out of which they grow are not clearly understood, and the infinite variety of their development and expression can only be determined by a study of each individual.

There is a general complaint through industry that we are not breeding leaders; in the movement of subordinate executives to the places of larger responsibility we find them hidebound by rule and regulation, limited in knowledge beyond the scope of their special skill, and unable to meet changes in condition with courage, firmness of action and self-reliance.

The agent of a hundred years ago who represented his principal in a city a thousand miles away from the office was in effect entirely responsible for all the operations, the decisions and the developments within his sphere of action.

If we quote from the records of such a merchant we find: "Upon my return to this territory, after three years' absence, I was pleased to find that my agent had invested the monies I left with him to such advantage in the business and in other enterprises that they had yielded me a handsome profit, which he delivered to me upon my arrival."

This man was for months without any knowledge of the operations of his agent, the adventures which the agent had undertaken or the purpose to which the funds had been devoted. Communication and transportation were very difficult, the machinery of commerce was very cumbersome, and, as a consequence, there could be no centralized control. To-day the rapidity of communication, the effectiveness of transportation and the unified systems of mass operation enable the control to be centered in the hands of a few to such a degree that the responsibility of the subordinate supervisors is extremely limited and definitely bounded by rule and regulation.

The decisions to be made by these men are governed by the system laid down. In many instances they are governed in extreme detail. This discourages the development of the capacity for decision, limits the knowledge to the specialized series of operations under the immediate supervision and destroys, rather than develops, the capacity for wise leadership.

Not long ago I was in conference with the president of a large company employing many thousand men. We were talking about some obvious deficiencies in various departments of the organization. The president of this company asked me what, in my opinion, was the important reason for the defects.

In reply I said, "Most of your supervisors are not leaders; they are only skillful operators, and consequently they do not know how to handle men."

His reply was illuminating, he said, "You are probably right, Tipper; but we have to have a thousand supervisors; where can you find me a thousand leaders?"

It is interesting to note that most of the older leaders in business, whose wisdom and vision have been acknowledged and whose capacity was outstanding, received their education in business at a time when business in this country was small, the

rules and regulations were few and the powerful, centralized systems of control were not established.

These men grew out of the very opposite conditions of business from those which they left at the close of their career, without realizing the effect of the change upon the capacity of the younger executive.

It is not without interest that lawyers, newspaper men and energetic, dissatisfied men from many lines of industry have been responsible for the growth of the automobile, advertising and other new developments. In these new lines they have a sphere for decisive action, developments which permit them to govern the system instead of obeying a system already established.

Because these highly centralized, controlled, detailed systems of operation in industry and commerce tend to decrease the capacity for leadership among the supervisors there is a great necessity for a broader and more fundamental type of education to the supervisors, a better acquaintance with the structure and elements of business, more encouragement by the decentralizing process and more incentive for the improvement of their own departments by the allowance of flexibility in the interpretation of the system.

In many concerns salesmen are obliged to fill out a report blank so cumbersome in its detailed formality that it clogs any inspiration. Results as to calls, routing over the territory, methods of approach and so forth have gone so far that in some organizations the actual words of a solicitation are rehearsed and standardized. Similarly in the factory side of business, the systems under which the foremen and department heads are required to work are formally determined in such detail as to require little or nothing but obedience to these uniform developments. These things do not make for the education of supervisors into leaders.

There is little or no opportunity for the exercise of judgment, for the quality of decision or the expression of human understanding. Consequently we are crying for leaders, executives and men of understanding in industry to fill the places of those who pass out, most of whom were educated under a free industry and developed by the necessity for continuous decision and responsibility for action.

Meeting of German Automobile Manufacturers' Society

THE Society of German Motor Car Manufacturers held its annual meeting at Berlin recently. Dr. Sperling, the general secretary, made a report in which he referred to the fact that during the war productive capacity had increased enormously in all countries, whereas the sales possibilities had shrunk greatly. After numerous appeals to the Government the control of the sale of gasoline had been discontinued, but in view of the deliveries required by the Entente the sale of benzol could not yet be freed of control by the Government.

The Society co-operated with the National Committee on Aerial and Motor Vehicle Transport with a view to the revision of the motor vehicle law of Feb. 3, 1910, with the result that already the regulations regarding admission of types, the hauling of trailers, test runs and the trailing of drivers had been materially eased. Other matters under consideration were a revision of the lighting and warning signal requirements and the admission of small motorcycles.

Referring to the readjustment of prices, the speaker said that automobile prices had increased less in proportion than prices of raw materials, and the Society had begun negotiations with the raw material associations which were still pending, as without a decrease in the cost of raw materials it was impossible to reduce the prices of automobiles, as present prices barely covered the cost of production. Under these conditions it was impossible for the automobile manufacturers to meet requests sometimes made of them to fill old contracts at the agreed prices and that the Supreme Court in several decisions had agreed with this view of the matter.

In response to urgent requests of the Society during the past year the national government provisionally removed the export tax, in order to enable German manufacturers to compete in foreign markets. The export tax planned by the Entente would, it was said, absolutely exclude German motor cars, cycles and accessories from Entente markets and must therefore be declared unacceptable.

It was unanimously decided to hold an automobile show the coming fall. A resolution of protest was adopted against the proposed increase in the tax on motor cars and trucks. Finally Dr. Sperling reported on import and export policies, referring particularly to the closing of neutral and Entente markets by embargoes or excessive duties which in their effects were similar.

Flame Characteristics and Their Influence Upon Combustion

(*Continued from page* 1102)

ionized by some of the catalytic processes. Great turbulence also accelerates inflammation and aids in keeping temperatures down by the scrubbing action of the burning gases upon the cold walls. To decrease the noise of detonation and to prevent extremes of temperature the combustion-chamber should be without pockets and very compact, *but without parallel surfaces*, so that neither heat nor sound can be concentrated by reverberatory action. The spark-plug should be located so as to give the flames the shortest possible travel.

It is likely that kerosene and gasoline can be more effectively burned by so stratifying the mixture that ignition occurs in a very rich portion which burns out into an excess of air, or a supporting atmosphere. If properly done detonation could not occur as the fuel would occupy but a small place in the combustion-chamber. Being a very rich mixture the rate of inflammation would be high. Complete dissociation would not be likely to occur and could not cause auto-ignition if it did, as there would be very little opaque vapor beyond the flame-front. A well vaporized, very rich mixture burns first blue, then green, the green indicating a cracking into new smaller hydrocarbons. If enough air is available immediately after the cracking the green flame becomes blue again and is in no way objectionable except that it is about 50 per cent more radiant than the blue flame. With this method the air is not throttled; the fuel only is governed. An engine using this method of combustion would have steam-engine characteristics in a reasonable degree, without sacrificing economy, which is much more than can be said for present engines.

A Highway Platform

THE resolution on highways adopted by the Chamber of Commerce of the United States is a clear, direct statement of a reasonable highway platform. It is here printed:

"The importance of improved highways has already had recognition by the Chamber, and the highway development in the country has attracted wide attention. In order that funds now to be spent for highway construction may adequately serve the economic purposes which are becoming clearly recognized, the following fundamental principles should govern:

"Bonds should be issued by states and territories, counties or municipalities and Federal assistance furnished only for portions of highway construction which are reasonably enduring and permanent in character.

"Federal appropriations should be made only for assistance to state highways which will become a part of an interstate system.

"Federal assistance should be continued only to those states which adequately maintain highways for which there has been Federal aid.

"Most careful study should be made by the Federal Government, in co-operation with State governments, as to routes, the probable character of service over such routes, and the best form of construction to meet such service. These studies should include ultimate economies of location and design."

The S. A. E. Summer Meeting Papers

THIS editorial, written in advance of the semi-annual meeting of the Society of Automotive Engineers, but after opportunity has been given to read several of the papers to be presented, is to advise engineers who are prevented from attending the meeting not to overlook the valuable information contained in the papers contributed to the program. A number of the latter deal with the fuel problem or closely related subjects and add much useful information to that published as a result of research and reports made at earlier meetings. The current papers, some of which appear in this issue or will appear in later numbers of AUTOMOTIVE INDUSTRIES, are, on the whole, rather more specific than in many of the earlier papers on fuel subjects, indicating that much-needed data is being secured and that ideas heretofore expressed are beginning to take a more definite form.

As usual, the Bureau of Standards has contributed largely to the program, and the data contained in the paper by W. S. James, with its appendices by other members of the bureau's staff, are pertinent and of exceptional value in pointing out weaknesses in present designs of automotive equipment and in many other ways.

The discussion by Dr. H. C. Dickinson on the present status of knowledge regarding the so-called "knock" phenomena should help clarify and correlate in the minds of many interested the various more or less hazy theories in this regard which have been advanced from time to time.

The number of papers dealing with research are a pleasing indication of the increasing importance attached to this vital phase of engineering and industrial progress. If the appreciation of work of this character continues to grow at the present rate, and especially if executives come more and more to understand its value and see that it is adequately supported, it is safe to predict astounding progress in automotive development—a development that seems certain to maintain the commanding position which the automotive industry now holds as being the most progressive of all the great industries of to-day.

Help Secretary Hoover

IT is extremely interesting to note the friendly attitude of Congress toward increased appropriations for Secretary Hoover's proposed work in the promotion of business in this country and for export.

Secretary Hoover's ideas as to the function of the Department of Commerce are sound. His ideas of

gathering production data and publishing it for the benefit of all business interested is an especially good move at this time. Within the last few months a State investigating committee working in New York has shown that there is much secret gathering of data going on in some of the building trades and that the data so gathered is used exclusively for the purpose of maintaining prices by those firms which belong to the particular organization gathering these data. This plan is workable merely because these figures have not been otherwise gathered and published.

It would be well for the men concerned in the automotive industry to urge upon their congressmen the need for more intelligent data in business. A congressman is likely not to appreciate the importance of such figures. Perhaps he has never studied sales building. A letter to him from a manufacturer is likely to be very illuminating on this subject. There is no reason why the automotive industry should not court the fullest publicity, as it has nothing to hide.

Perhaps if the manufacturers would stop to think how much data can be gathered for the amount necessary to build one 16-inch gun, they would be better able to make a definite argument to the lawmaker to whom they write. Manufacturers should be quick to take advantage of the sales statistics figures that Secretary Hoover proposes to offer to them.

Loose Tax Talk

IT seems more than passing strange that the railroads, after a period of quiet, should again bring forth so prominently the cry against the motor truck running on public highways without paying a high tax for the privilege of doing so. This sentiment, which has often appeared in railroad literature of late, became the prominent feature of Julius Kruttschnitt's testimony before the Senate Committee on Interstate Commerce.

One would hardly believe that the chairman of the Southern Pacific or any other western railroad would enter much of a protest against public aid to transportation in the interest of the development of the country. Certainly the western railroads have profited by public lands and funds.

But why this constant and everlasting dispute as to the use of the highways and who pays for their use? The people of the country, in their tax bills, supply the money for the building of the highways. The motor vehicle owners pay a special tax for the maintenance of the highways—or at least that is what the money should be used for. If special interests are taxed for the use of these highways, it merely means that this special interest will add this tax money to the price of the product hauled and in that way get it away from the mass of the people. In passing on this tax the special interest will take its toll coming and going. So the bill paid by the consumer mounts.

Does anyone suppose that if one of the large oil companies is compelled to pay additional truck license fees of $1,000,000 a year that this company will not raise the price of kerosene? And make an additional profit on the advance? If there is any such person—but why go on?

Why should a fleet owner, who handles his transportation units efficiently and moves freight economically for the benefit of the people, be taxed merely because railroad management is so inefficient and because the railroad equipment belongs to a day that has passed?

How can this country advance if progress is to be taxed to enable the business of yesterday to pay a profit? It would be just as reasonable for Mr. Kruttschnitt to advocate a return to earth roads and ox-carts and to sailing vessels, so that his road can have a monopoly of freight haul. Why not a rule of reason as to motor vehicle taxes?

Inaccurate Statistics

THERE appears to be an epidemic of articles being circulated and printed about the automotive industry that are based on figures that are weird and wonderful. Where these figures are obtained is impossible to state. They are not the figures compiled by the N. A. C. C., the several Government bureaus nor by AUTOMOTIVE INDUSTRIES. One of these articles was recently submitted to the Society of Automotive Engineers by a manufacturer for the program at the semi-annual meeting at West Baden. This paper was carefully read by the S. A. E. papers committee and rejected because of wrong figures used to reach conclusions. Later this paper was printed in the main in *The Annalist* of New York and, since its printing there, has been distributed to the press by an advertising agency. What reason either the writer of the paper or the agency may have for attacking the industry through inaccurate figures is not apparent. An article based on correct figures would be just as effective in promoting the use of alloy steel.

Benefits of Leadership

WHEN a supervisor, foreman or executive possesses the power of the well-known centurion of the Bible, he is strongly tempted to exercise that power without regard to its ultimate effects. Why take the time and trouble necessary to lead a group of workers when all you really have to do is to tell them?

There is one purely selfish reason, besides other more altruistic ones. There is always likely to come a time when the balance of power is changed. The supervisor may want the workers to do something that they do not have to do unless they so desire. If he is a leader and has been in the habit of leading them in small things, they will voluntarily follow him in the big things as well. But if they have done his bidding merely because of necessity, they are almost certain to exercise their power when the tables are turned. Some such psychological reaction is responsible for many of the labor troubles of the last few years. Intelligent handling can prevent its being responsible for future difficulties of a similar nature. The present time is favorable to the study of this problem. Leaders will be needed in the future; their development can begin now.

Bank Reserves Ample, Harding Says

Credit Situation Again Near Normal

Reserve Board Head Urges Business on Substantial Lines—Defends Bank Forms

KANSAS CITY, May 23—Governor Harding of the Federal Reserve Board came to Kansas City Saturday as the guest of the Kansas City Motor Car Dealers' Association. In two conferences with directors of the association and representatives of the industry from the various states of the Tenth Federal Reserve District and in an address to 350 bankers and automotive distributors of the district, the Governor declared that methods of handling paper offered for rediscount could now be changed in view of the strong situation of the Federal Reserve Bank. **He implied that individual banks were also in unusually strong position, and could doubtless modify the restrictions they had been making.**

Governor Harding went so far as to urge aggressive merchandising, and there was more than a hint that the conditions of banks offered a welcome to borrowers for legitimate business purposes. There was also more than a hint that among these borrowers, especially among those whose papers would be acceptable to all Federal Reserve Banks, was the automotive industry. Governor Harding did not explicitly declare that motor car paper would now be rediscounted at all Reserve Banks, but he gave suggestions to the distributors present on preparing forms in such a way that their paper could be handled with a minimum of delay in rediscounting processes. The explicit prediction that paper heretofore not accepted for rediscount might soon be accepted was made by Governor Miller of the Kansas City Bank, the Federal Reserve Bank of the Tenth District, which has not rediscounted motor car paper for many months.

Meet in Conference

Governor Harding was met by the directors of the Kansas City association at the train Saturday morning. At breakfast and during the motor car ride following with the distributors and again in the afternoon Governor Harding discussed with the dealers the relation of the Federal Reserve Banks to the automotive industry. The afternoon conference included representatives of automotive associations from many States. Governor Harding spoke at the City Club at noon; outlining the financial history of the past two years. His main address was at the dinner in the Muehlbach Hotel given by the Kansas City Motor Car Dealers' Association in his honor, at which 350 local and territory bankers and automotive distributors of passenger cars, trucks and tractors were present. E. E. Peake opened the meeting, John B. Butler, president of the Kansas City association, acting as toastmaster. The governors and chairmen of the Federal Reserve Banks of San Francisco and Minneapolis, who had come to Kansas City for conferences with Governor Harding, were introduced. The toastmaster then called on J. Z. Miller,

New Goodyear President a Schlesinger Protege

MILWAUKEE, May 23—Edward G. Wilmer of Milwaukee, who on May 17 assumed charge of the Goodyear Rubber & Tire Co. of Akron as president, has been for several years regarded as one of the coming leaders of business and finance in American affairs. He is 38 years old and a graduate in law at George Washington University, Washington, D. C., but he never has devoted himself to exclusive practice.

Upon being graduated, about twelve years ago, Wilmer was engaged by the late Ferdinand Schlesinger of Milwaukee, one of the most prominent figures in the American iron, steel and chemical industries, as a personal adviser and legal representative. Wilmer rose rapidly and became one of the most prominent men in the vast Schlesinger enterprises, serving as vice-president of the Steel & Tube Co. of America, a consolidation of a dozen large concerns; the Newport Co., one of the largest chemical concerns in the world, and the Milwaukee Coke & Gas Co. He is regarded as one of the keenest business executives, particularly in financing, that this country has produced in the last decade.

His accession to the presidency of one of the world's largest rubber and tire concerns is recognition of this remarkable ability. It also is significant of the entrance of the vast Schlesinger interests into a new field and a financial participation in the reorganization of the Goodyear company, which is backed by a historic record in iron, steel and chemicals.

THOMART TRUCK CUT $690

KENT, OHIO, May 21—The Thomart Motor Co. announces a reduction of $690 in the price of the Akron multitruck chassis, making it $1,995, f.o.b. Kent. The explanation is made by W. G. Thompson, president of the company, that the company's inventory has been liquidated and that production costs have been reduced to such a point that a lower price is justified.

Parts Orders Drop in Last of Month

Factories Report Hold Up in June Releases—Price Uncertainty Held Cause

NEW YORK, May 25—Uncertainties in regard to retail market conditions are leading manufacturers of motor vehicles to proceed with extreme caution in making commitments for materials. This fact is disclosed by reports made by the leading motor and accessory manufacturers of the country.

The total of business for May probably will equal that of April, but it was heavier for the first two weeks than for the first half of last month. Since that time many releases have been countermanded and there have been a few cancellations of new orders. Indications now are that the volume of business for June will not equal this month. A considerable number of June releases have been held up in the last ten days.

While orders for supplies are showing a tendency to decline, however, collections for May have been better than at any time since the slump began. The gratifying improvement recorded in April has continued and in numberless cases past due accounts have been liquidated. There has been heavy liquidation in the last three months in the current indebtedness of automobile manufacturers, and there is no evidence that payment of obligations in future will be any less prompt.

Although parts makers have felt a slowing up in business from vehicle manufacturers, there has been no slump whatever in the trade with jobbers and wholesalers. In fact, it has steadily continued its upward trend, and June promises to be better than May. Collections in this branch of the trade are excellent.

It is evident car and truck makers are determined not to pile up inventories. The experience of last summer in this direction has made them exceedingly wary. They are buying on a hand-to-mouth basis to meet only immediate needs. The falling off in orders from them is bound up closely in the question of price cuts.

Lines which have not cut have suffered a sharp decline in sales, while those which have made reductions this spring have felt a marked rebound. The buying public seems to take no further account of price reductions made last fall. The market is decidedly jumpy and gives every evidence of needing the stabilizing influence which would come with immediate determination by manu-

Dealers Protest Excise Tax Burden

Senators Are Told Why Levy Is Unfair

Harry Harper Spokesman for N. A. D. A. Committee—Strong Arguments Presented

WASHINGTON, May 23—Vigorous protest against the assessment of proposed increases in the excise taxes on automobiles and other forms of discrimination was made here to-day by the National Automobile Dealers' Association in presenting its recommendations for internal revenue revision to the Senate Committee on Finance. It expressed the belief that any further addition in taxes upon the motor vehicle would have to be borne in large measure by the dealers and that the sales resistance engendered by such increase would seriously jeopardize the success, progress and prosperity of the entire industry. While the general tax program of the Association is in harmony with the plan of the National Automobile Chamber of Commerce, its argument differed in that it showed the harmful tendencies of present and proposed taxes from the standpoint of the dealer.

The case of the organized dealers was presented by H. B. Harper, chairman of the association's taxation committee. The Senate committee listened attentively and there were few questions to interrupt his speech. He escaped the grilling which the committee forced upon witnesses for the manufacturers.

Harper pointed out to the committee that the interests of the dealers are separate and distinct from those of manufacturers. He said that dealers are large tax-payers in their own communities in addition to taxes paid to the Federal Government: excise, excess-profits and income taxes. It was his contention that the automobile industry as a whole is not protesting against its fair share of taxes but believed it was time for a more equitable distribution of the tax burden to other commodities and trades.

Dealer Mortality Highest

As to the reported profits of automobile dealers, Harper directed the attention of the committee to the fact that the average dealer nets a profit of between 3.5 per cent and 4.5 per cent of his gross sales. He laid emphasis upon the contention that "in no other American industry is the mortality so high as among automobile retailers. Hundreds of dealers, in order to stimulate the sales that have fallen off so noticeably in the last six or eight months, are absorbing the tax and the handling charge and in addition, in 90 per cent of all sales they are taking in a used car for considerably more than its value in order to sell, mainly for the sake of keeping their organizations moving and looking forward to a betterment of business conditions."

To establish the fact that the automobile is essential, the spokesman declared that it is a business car first and foremost and any recreational uses it may have are but incidental to its primary purpose, which is personal transportation. Sixty per cent of all automobile mileage is for business purposes. Ninety per cent of all automobiles are used, more or less, in business. Instead of being a burden upon its owner, the automobile has added 57 per cent to the productivity and effectiveness to the average automobile owner.

Denial was made of the theory that a tax on automobiles is to pay for surplus wealth. Harper said: "The tax

(*Continued on page* 1134)

Business Paper Editor to Be Hoover Assistant

NEW YORK, May 21—Fred M. Feiker, vice-president of the McGraw-Hill Co., Inc., and one of the best known men in the business paper field, has been appointed assistant to Secretary of Commerce Hoover, to assist the department in effecting a contact with business. The Secretary is also holding monthly conferences with the National Conference of Business Paper Editors, with which work Feiker has been very active.

Feiker has been engaged in business paper work for fourteen years. He received an electrical engineering degree at Worcester Polytechnic Institute in 1904, was two years in the technical publicity department of the General Electric Co., went with the Shaw papers to start *Factory* and became chairman of the editorial board, remaining eight years with Shaw. He then joined the McGraw-Hill Co. as editor of *Electrical World*, and became vice-president of the company.

He has secured a leave of absence of several months from the McGraw-Hill Co., with which he has been for six years, and expects to begin his work with Hoover before June 1.

LEACH OFFICERS RENAMED

LOS ANGELES, May 23—M. A. Leach was re-elected president and all members of the board of directors also were renamed at the annual meeting of the stockholders of the Leach Biltwell Motor Co. Other officers also were reelected. More than two-thirds of the stockholders were present. Financial reports showed that the company had successfully weathered the depression.

Canada Tax Finds Favor of Dealers

Domestic Made Vehicles Will Be Benefited Over United States Products

TORONTO, May 21—Realizing the Government's need of revenue, the motor manufacturers, importers, distributors and dealers are not disposed to adversely criticize the budget. The importers of United States cars and trucks are faced with a considerably greater additional impost than the distributors and dealers in domestic made motor vehicles for not only do they face a doubling up of the sales tax, but also an increase in duty arising out of the new basis of its determination—the United States price plus exchange.

They are naturally not jubilant over the change, especially as it slightly increases the differential in favor of Canadian-made cars and trucks. However, this offsets the advantage given the importers under the initial imposition of the so-called sales tax.

On the whole, the automotive trade and industry is delighted that automotive products have not been singled out for special taxation, especially as this is generally believed to indicate an appreciation by the Government of the fact that motor vehicles are no longer luxuries or non-essential, but utilitarian necessities—the greatest of time and labor-saving devices.

In giving the lie to wildcat rumors to the effect that extortionate taxes were to be imposed—rumors that carried with them the assurance that they were inspired by authorities in the confidence of the Government—the budget relieved the minds of many who lent these rumors credence, of apprehensive tension and anticipatory worry.

The duty now applies on the United States manufacturers' price plus exchange at time of shipment, and the sales tax applies on the resultant. Comparatively, however, the prices of cars have not been much advanced, and some not at all.

ADD EMBEZZLEMENT TO THEFT

WASHINGTON, May 23 — Senator Nelson's bill amending the "Act to punish transportation of stolen motor vehicles in interstate or foreign commerce," was passed by the Senate without change. The amendment adds the word "embezzlement" so as to include not only cases where the automobile is stolen but as well cases of embezzlement. It relates to transportation of embezzled property in interstate, not in state commerce.

Willys's Cars Join in New Price Cuts

Overland Down to New Low Point—Knight Drops $300—Scripps Off $250

TOLEDO, May 20—Willys-Overland and Willys-Knight have announced price reductions effective June 1 constituting the second drop in Overland cars within the last year, totaling 33 per cent from the price last summer. Open models now selling at $895 are reduced to $695, coupe from $1425 to $1000, and the sedan from $1475 to $1275. Willys-Knight prices for the touring car are reduced from $2195 to $1895 and the same reduction is made on the roadster. The coupe was reduced from $2845 to $2550 and the sedan from $2945 to $2750.

The new price on Overlands is $150 less than the lowest price for which this car ever sold. It is made possible, according to John N. Willys, by the sale of the car which already has passed the 140,000 mark and by the anticipation of the great saving through increased factory efficiency, manufacturing cost and increased volume.

"We have decided to anticipate every possible saving and are setting our prices at rock bottom June 1," said Willys. "We are going the whole route right now. The price is one which we have long anticipated we might some day reach in Overlands and the car itself is better than ever. At present we will take a loss on every Overland we sell, but expect to make this up in increased volume and increased material saving."

Scripps Reduction $250

DETROIT, May 21—The Scripps-Booth Corp. announces a price cut averaging $250, effective to-day. Prices for the touring car are $1,295, roadster $1,275, coupe $1,950, sedan $2,100. This is a decrease on the touring car of $250, roadster $270, coupe $265 and sedan $195. This is the first cut for Scripps-Booth, but the company did not increase prices when others did last spring and summer.

Ford Discontinues Bonus; Will Increase Wages

DETROIT, May 20—The Ford Motor Co. has abolished the yearly bonus, according to the Ford *News*, its official organ, and in lieu thereof has increased wages in an amount aggregating what each employee would receive annually under the bonus system. This is paid in 26 installments on the regular semimonthly pay day. Announcement was made this week that the bonus was being paid in installments in order to protect men leaving before the end of the year. The *News*, however, corrects the announcement and states it is designed as a wage increase and applies to every man on the payroll May 1.

The statement also says the plan to supplant the bonus was decided on last January, and all employees on the roll May 1, who have been working since the plant reopened in February, will receive back pay in an amount equal to the difference between the wages already received and the amount they would have received under the increased wage plan.

In order that every employee may understand the bonus has been discontinued and know what his increased rate will be, together with the number of back payroll hours to which he is entitled, cards bearing the information are being inserted in pay envelopes. Men employed since May 1 are being paid the standard rate, which the *News* says provides a minimum of 75 cents an hour. Discontinuance of the bonus does not affect the investment plan under which employees may invest up to one-third of their wages.

Paige Report to Show Satisfactory Earnings

DETROIT, May 21—The annual report of the Paige-Detroit Motor Car Co. is now being prepared and is expected to show satisfactory earnings. In the first quarter of 1921 Paige shipped 3004 cars, against 4755 the first quarter of 1920. Since the first of the year the company has paid off all supply bills and is in a position to discount all its bills. Its bank balances are around $1,000,000 and bank loans have been cut in half. The company now is operating on a 60 per cent basis, turning out between 50 and 60 passenger cars a day. The reduction in production schedules was ordered in anticipation of unsettled market conditions. Best sales conditions are found in New England, New York and Pennsylvania, with Ohio, Indiana and Wisconsin coming next.

Employment Drops Off First Time in Months

DETROIT, May 20—A net decrease of 1776 men employed was shown by the labor report of the employers' association here today. It was the first week the employment situation had not improved by several thousand since the industrial revival began. The 79 member firms now employ 116,721 workers.

TRUCKS NOW SECOND CLASS

NEW YORK, May 23—The traffic department of the National Automobile Chamber of Commerce has been advised by the chairman of the western classification committee that favorable action has been taken on the request for reclassification of motor trucks and chassis shipped in carload lots west of Chicago and the Mississippi River. This classification will be changed from first class to second class. The consequent saving in freight charges on a 15,000 lb. load of trucks will amount to $35.35 on shipments to Kansas City or Omaha; $68.25 to Dallas, Galveston and Houston, and $88.50 to Denver with other western points in proportion. Pacific Coast rates are not changed.

Used Cars Pile Up as New Sales Grow

Coast Business 85 Per Cent Trade-Ins—Lower Gasoline Stimulates Demand

SACRAMENTO, CAL., May 23—Developments of the spring have worked for the benefit of motor car dealers here, generally speaking. Business has returned to a semblance of pre-war conditions, although disturbing factors have not been wanting.

One of these is the recent price drops of some cars. These have worked to the advantage of the dealers in these lines, but on the other hand, have caused some little difficulty among would-be purchasers of other makes, who show a tendency to hold off in the hopes of more price cutting.

The reduction in the price of gasoline, coupled with the announcement that there is plenty of motor fuel in sight for the summer, has stimulated sales. The uncertainty of gasoline last year was a very disturbing factor to the trade here.

The used car market is sluggish. Second-hand cars are piling up, as 85 per cent of the sales here are estimated to be trades for old cars. Vacant lots about the city are being used to store and display these used cars, which are the chief concern of the dealers.

The Miller Automobile Co., Dodge dealers here, have instituted the practice of rebuilding all used cars taken in, turning them out with a "Maco" guarantee. This has been quite successful, as has also the plan of the Sacramento Buick Co. along the same lines, in rebuilding, repainting and retopping its used cars and selling them with a new-car guarantee.

Pointing out that the buyer of a used car saves the dealer's profit, war tax and freight charges, the latter not inconsiderable in this territory, these two firms have been keeping their used car departments quite clear of any undue accumulation of second-hand automobiles.

CHEVROLET MOVES OFFICES

NEW YORK, May 20—The production, material, purchasing, traffic, engineering and production and plant engineering departments of the Chevrolet Motor Co. have been moved to Detroit on April 15 and will be located in the General Motors Building. These departments will be under the general direction of K. T. Keller, manager of manufacturing. The offices of the general manager and of the general sales and accounting departments remain in New York.

INDORSE RETURN GOODS CHARGE

CHICAGO, May 20—The Midwest Rubber Manufacturers' Association at its meeting here adopted a resolution recommending that a minimum charge of 5 per cent be imposed on merchandise returned for credit or exchange or on the shipment of new goods.

Price Concessions Necessary, Says Bank

Appreciation of Reductions Will Stimulate Business, Declares Wisconsin Institution

MILWAUKEE, May 23—"There is some uncertainty as to whether or not the improvement in the motor car industry is permanent," says the May issue of *Business and Financial Comment*, issued monthly by the First Wisconsin National, the largest bank in Milwaukee. "Judging from recent and somewhat radical reductions in the prices of passenger cars and tires, concessions were found necessary to stimulate new business and hold the ground gained early in the year. So far as Milwaukee is concerned, the automotive equipment industry did not gain as much in the past month as in the previous month. Orders were more numerous, but probably ruled 50 per cent below the corresponding month in 1920. Operations are running on the average from 45 to 55 per cent. The trend of prices is regarded as uncertain."

Speaking of the Milwaukee metal trades, the report says: "The metal trade shops, with the exception of those supplying the automotive industries, practically marked time during the past month. All lines using iron and steel are clouded with uncertainty and improvement is contingent upon wages and prices in the basic industries. Machine shops of all descriptions in Milwaukee are probably operating on the average of not more than 40 per cent. Certain firms supplying machinery for road making, oil production and the automotive market make a better showing. In the steel industry at large, sheets and structural materials for building make up the greater proportion of the available business."

In the last week to ten days a number of passenger car manufacturers in and near Milwaukee have reduced production schedules because of the accumulation of finished products resulting from a decline in distributers' and dealers' orders in the first half of May, largely because of adverse weather conditions. This is believed, however, to be only a temporary matter, as new business is again developing more actively.

Business Made to Improve

Encouragement is found in the keynote paragraph of the First Wisconsin's review, which says: "The events of the last 30 days have yielded much justification for confidence. Business improvement cannot be expected unless somebody does something to make it improve. A good deal of appreciation is now being displayed. Just as depression resulting from sharply falling prices last year spread from some lines of business to others, so renewed activity in cotton and woolen goods, motor vehicles and new construction applies a stimulus to set other lines of trade going again.

"Prospects are brighter than they have been for many months. But much remains to be done before this depression will become a memory. The sticking points that will still have to be overcome are: The readjustment of labor costs in conformity with the movement of prices; the reconcilement of prices with one another; some having gone too low and others not low enough; and perhaps most important of all, the devising of means whereby we can use our superior credit position as a basis of selling goods to foreign countries."

Los Angeles in Turmoil

LOS ANGELES, May 24—Dealers here refuse to commit themselves to an opinion upon the effect of announcements of price reductions upon the automobile sales conditions. One point upon which all agree and none is reluctant about expressing an opinion is that the used car business is again in a state of turmoil. One dealer is reported to have said the price reductions announced within the past two weeks have cost him $10,000 in shrinkage on used car values. It is too early now to hazard a prediction as to the stimulus that will result in increased sales of those cars prices of which have been reduced.

The Al G. Faulkner Co., California distributor of the Marmon, has been placed in the hands of a receiver upon petition of the Nordyke & Marmon Co., which is said to have claims against the dealer amounting to $150,000. The Faulkner company has been operating on a large scale throughout the State. Two large establishments have been maintained here and another in San Francisco.

Cleveland Acts to Stop Ohio Truck Weight Bill

CLEVELAND, May 23—The Cleveland automobile industry has never been aroused over a matter as it has been with respect to the Burke bill, which limits the weight of truck loads. The measure has been passed by the general assembly and it is now awaiting the signature of the Governor before it becomes a law.

One hundred representatives of the city's automotive and commercial interests at a meeting in the Hotel Winton unanimously voted to send a delegation to Columbus to protest against the bill, which was pronounced an "economic disaster" should it become a law, not only to Ohio's truck and tire industries, but also to every consumer who benefits from transportation provided by trucks.

SPROUL SIGNS FUEL TAX BIIL

HARRISBURG, PA., May 23—Governor Sproul to-day signed the "cent-a-gallon" gasoline tax.

This law affects every sale of gasoline to a consumer in Pennsylvania. More than $2,000,000 a year will be realized in revenue by the measure's operation.

The tax becomes effective on Sept. 1. It is estimated that Philadelphia, for instance, will receive $350,000 a year.

Reduced Cars Hold Sales Leadership

Wholesale Business Advances in New York Territory—Truck Sales Grow

NEW YORK, May 21—The passenger cars whose prices have been reduced within the past three weeks are still selling strongly in the New York territory. In most cases retail sales have not been as strong as they were during the first week, but the volume of business, as compared with what it was before the reductions, is satisfactory to the distributors and branch houses concerned. In the wholesale, the past week's volume of business has been considerably better than the first week of the reduced prices, indicating that out-of-town dealers have not been able to take their story to the public quite as quickly as metropolitan merchants.

In the case of two or three cars whose prices were reduced during the present week, the response of the buying public was practically instantaneous and there is a more general feeling among New York distributors than there was a few months ago that the price question is of paramount importance in the view of the public.

In lines which have not cut, or if they have cut did so months ago, there is marked stagnation. One or two of the most popular lines in this class have come somewhere near resuming their old stride after two weeks of slow sales immediately following the most sensational of the price cuts. However, even these lines are having to batter down strong sales resistance based on the price question. Some other lines which hitherto have been selling well have been practically standing still since May 1. Generally speaking, business outside of that enjoyed by dealers in cars recently reduced in price cannot be said to be good.

Truck sales are showing a slightly upward trend. Sales are particularly good in two or three classes of low and medium priced light weight trucks.

The heavier trucks are beginning to feel the competition of offerings here of American and foreign trucks brought in from former war areas of Europe, and priced at low figures. When these trucks first appeared in the open market, buyers were suspicious of their condition and sales were not numerous. Within the past two or three weeks, however, there have been enough of these sales to cut in a considerable degree the revenues of dealers and branch houses handling several prominent lines.

Accessory sales continue to run along on something like 60 per cent of last year's volume.

TRUCK MERGER EFFECTIVE

KENOSHA, WIS., May 20—The merger of the Winther Motor Truck Co., the Marwin Motor Truck Co. and the Kenosha Wheel & Axle Co. became effective to-day.

Crop Outlook Helps Business in South

May Leads April in Sales and Prospects Are Numerous—Credit Steady

NEW ORLEANS, May 23—The period of readjustment in the automotive industry in the territory supplied by the dealers and distributors of this city seems to be nearing an end. May sales, up to the 20th of the month, were greater for virtually every dealer in New Orleans than they were for the first three weeks of April, while prospects were reported as more numerous than they had been since June, 1920.

This steady improvement in automobile sales is considered by the dealers to be due, to a great extent, to the recently-devised co-operative sales plans for the cotton crop, and the revival of the War Finance Board, with accompanying aid from it in disposing of the South's cotton in Europe. Two other considerable factors are the temporary tariff on sugar, the effects of which already are being felt in an increased optimism among the sugar planters and their workmen, and the development of a better class of automobile salesmen.

Payments are much steadier and more regular, and collections considerably easier than they have been since last year. Improvement in this regard also is shown in the country, where conditions generally have been much slower to readjust themselves than in the cities. Improvement in collections has been so great that virtually all the New Orleans dealers are taking their cars promptly out of the railroad warehouses, meeting their notes as they fall due, and discounting some of their paper in advance.

All this has put the dealers on a more independent footing, and has considerable influence with the banks, for some of the short-sighted bankers, it must be said, were expressing themselves widely and freely as to the doubtful future of the automotive industry. All of these doubters have been discredited and cast out by the gain in this industry in the past 60 days in all the Southern states.

One of the greatest aids in this development, especially among the Louisiana dealers, has been the steady, consistent and encouraging work of the New Orleans Automobile Dealers' Association.

TEXAS ROADS TO OPEN STATE

FORT WORTH, May 20—With the spring time and the new automobile season has come the greatest road-building boom in the history of North and West Texas. Pikes costing $50,000,000 are under construction from the four corners of the state. And on top of this huge sum, bond elections will be held in many farming and ranching communities this month to authorize more funds.

Each new bond issue voted and each new highway contract awarded means sections hitherto inaccessible to the machines will be opened up.

STUDEBAKER BUSINESS NEAR YEAR'S TOTAL

NEW YORK, May 20—A summary of sales of Studebaker cars in the Greater New York district to April 30 shows 1029 sold to this time, only ten less than for the whole year of 1920. Sales in April were 386 cars, as compared to 149 in April, 1920. The 1029 cars sold in the first four months of this year represent an increase of 529 over sales for the first four months of 1920.

Toledo Plants Active As Business Revives

TOLEDO, May 23—There are 1200 workers now on the payroll at the plant of the Electric Auto-Lite Corp., one of the subsidiaries of the Willys Corp., according to C. O. Miniger, president. Two weeks ago the force numbered only 800. The farm lighting business as well as the automobile lighting plant orders are picking up, he reports.

Nearly 200 men are now being employed at the Toledo Chevrolet plant where transmissions are assembled. A few at a time are being called back to work.

Daily additions to working forces are also being made at other automotive equipment plants here. The Mather Spring Co., the Bunting Brass & Bronze Co., the Milburn Wagon Co., and the Champion Spark Plug Co., all report increased business in the last two weeks.

Premier Starts Suit for Skelton Insurance

INDIANAPOLIS, May 21—Payment of a $200,000 insurance policy on the life of L. Sherman Skelton, former president of the Premier Motor Corp., is being fought by the Travelers Insurance Co. on the ground that Skelton misrepresented the condition of his health when he took out the policy. A cross complaint was filed by the insurance company in answer to a suit brought against it by the Premier Motor Corp. and other administrators of the Skelton estate, who sought payment on the policy under which the Premier company was the beneficiary. The policy was assigned by the motor car company to the Fletcher American National Bank of this city.

CONFER ON BRAKE LININGS

WASHINGTON, May 20 — Recommendations for a standard method of testing brake lining materials for automotive purposes, made following a recent conference at the Bureau of Standards, were discussed last week by engineers of the bureau with representatives of nearly all the manufacturers of this class of material, as well as of the Motor Transport Corps and the standards committee of the Society of Automotive Engineers.

Continued High Sale Looked for in June

Central Ohio Territory Finds Weather Big Aid—Truck Business Increases

COLUMBUS, May 23—With the arrival of better weather conditions, there is a noticeable increase in the demand for automobiles in Columbus and central Ohio territory. This is the report of a large number of retailers in the passenger line of vehicles and it is believed by them that conditions will continue to improve from this time on. At least preparations have been made for a good demand for passenger cars during the month of June and possibly for a portion of July.

Dealers in passenger cars report a growing demand for closed jobs. The closed body is now the popular thing and there is a growing scarcity of such cars in central Ohio territory. Touring cars are still selling well and the open runabout is also in good demand.

In the farming sections a gradual increase in the demand for cars is reported and dealers in the strictly rural sections are becoming quite busy again.

Truck sales are now increasing appreciably. For a time there was a lull in the demand for trucks, but now commercial houses are doing considerable shopping around. The strongest feature of the commercial vehicle market is for the one, the one and a half and the two-ton trucks. The heavier trucks are not selling as well as the lighter varieties. The light delivery wagon is moving fairly well under the circumstances.

There is also a sort of spurt in the repair business in Columbus. All of the service stations and many of the repair shops report a good run of business. The overhauling of passenger cars is going on rapidly and most of the larger shops are pretty well crowded with work. Parts departments are doing a good business and many replacements are being made.

GASOLINE STOCKS INCREASE

WASHINGTON, May 20—Increased use of automobiles is reflected in the refinery statistics of the Bureau of Mines, showing that the daily average consumption of gasoline for March was 2,600,000 gal. larger than that of February, and 2,900,000 gal. than in March, 1920. The daily average production of gasoline for March was 322 gal. less than the production for February, though it exceeded the production for the same month last year by 165,000 gal. Stocks of gasoline increased during March to 713,043,480 gal., the largest stock of gasoline on record.

The daily average production of lubricating oils was 2,354,945 gal. during March, a decrease of 232,000 gal. Total stocks of lubricating oil on hand at the refineries March 31 amounted to 223,414,093 gal. as against 130,632,597 gal. for March, 1920.

Dayton Entertains Engineer Delegates

McCook Field Inspection Followed by Instructive Talks on Aircraft Studies

DAYTON, OHIO, May 21—Several of the S.A.E. members en route for the West Baden convention, and members of the A.S.M.E. bound for their Chicago meeting, were entertained here to-day by the Dayton Section of the S.A.E., McCook Field and the Dayton Engineers' Club.

Given as a joint meeting of the A.S.M.E. and S.A.E., those who attended were afforded an unusually complete exhibition of all types of aircraft both on the ground and on the wing. During the entire morning McCook Field was thrown open to the engineers, who were taken on a complete tour of inspection through practically all the departments.

After luncheon at the field a technical session was held at which military and civilian members of the McCook field staff presented a series of papers covering phases of airplane engineering. The evening was given over to a dinner at the Engineers' Club where C. F. Kettering, Joseph Steinmetz, head of the aircraft section of the mechanical engineers and V. E. C. Handley Page, were the speakers.

Twenty planes of all descriptions were lined up on the field, eight of them taking the air. Among those flying were the Junker all-metal plane, the big 1200 h.p. Caproni, and the 60 h.p. Messenger, which, with its three-cylinder engine, afforded an interesting contrast with the roaring giants equipped with two and three Liberty engines.

Members of both societies exhibited greatest interest in the radio-controlled wagon which was started, stopped and steered to left and right by wireless. The wagon is a torpedo-shaped box and its manipulation from a distant station made its movements seem almost uncanny as it would run up to a group of visitors, stop, blow a horn, ring a bell and then whirl about and start off in another direction.

Technical Session Interesting

The technical session proved to be one of the most interesting aeronautical meetings the S.A.E. has held. Papers were presented on aluminum air-cooled cylinders, by E. H. Dix, Jr.; radio-telegraphy and telephony by O. E. Marvel; carbureter design, C. F. Taylor; radiators, Lieut. Bayard Johnson; camouflage, C. R. Young; air-cooled engines, S. D. Herron; air photography, Lieut. E. E. Aldrin, and synchronization of propeller and machine gun fire by H. O. Russell.

Through these varied papers the engineers present were given a rapid panorama of late developments in the field of airplane activity. Speaking of the attempts to cast an aluminum air-cooled head on a steel cylinder, Dix stated that experiments had gone far enough to show that the idea is feasible. In effecting a juncture between the steel and aluminum various coatings were used. Tinning and sherardizing were best with advantage in favor of the latter because the melting point of zinc is higher. Micro-photographs of steel cylinders with the aluminum head show that there is a good juncture between the two metals. After various experiments for materials to be used as valve seat inserts and spark plug bushings, low phosphor-bronze has been found best because of the nearness of its coefficient of expansion to that of aluminum.

Discuss Aluminum Alloys

In making the castings elaborate care must be taken to prevent cracking. The cores in the later castings are being preheated to 500 deg. Fahr. before pouring and then the entire mold is placed in a core oven and kept at 500 deg. Fahr. for an extensive length of time. The best aluminum alloy for the purpose so far has been aluminum-silicon. Its strength falls off 2½ per cent at 300 deg. Fahr. and 20 per cent at 500 deg. Fahr. It is satisfactory within the limits of working temperature in the engine. It is also good on porosity test. The Bureau of Standards is at present obtaining data on other physical characteristics. The alloy has about 7 per cent silicon.

In discussing air-cooled engines generally Mr. Herron stated that it is now possible to show just as good m.e.p. and output figures as with water cooled, without the disadvantage of freezing in a nose-dive. To date, 12 cylinder engines up to 240 h.p. have been built and give satisfaction. Brake m.e.p.'s of 130 lb. per sq. in. have been attained and the cylinders have been built up to 8 by 10.

Lieut. Johnson in discussing airplane radiators pointed to the depth of core possible because of high air velocity. He stated this to be the leading difference between airplane and automobile radiators. For the Liberty engine it is necessary to pump 73 gal. of water per min. through the jackets to meet the required minimum of 18 deg. heat range. For this reason there must be no restriction of flow.

The method of testing radiators is to climb the machine at its maximum rate and then take readings at every 1000 ft. The results are plotted curves of mean water temperature and air temperatures being drawn.

Plea for Cheaper Planes

At the dinner both Messrs. Handley Page and Kettering made a plea for lower-priced planes and engines. Kettering said that the first step in securing "commercial aviation" would be to develop a 150 h.p. engine to sell at $750. The reason there is no commercial aviation to-day is because there are no planes which can be built economically. To put it in his own inimitable way, "There are too many gim-cracks—There is not enough intelligent ignorance among aircraft engineers—There are too many reports on matters which 'can't be done'."

Non-Combatants Offer Strong Car Markets

Studies by Secretary Hoover Show Stabilized Exchange Helpful Factor

WASHINGTON, May 26—Study of markets for American automobiles in the Netherlands, Norway, Poland, Spain, Sweden and Switzerland as conducted by the Commercial Attachés of the Department of Commerce shows that American exporters have a wide field which could be easily cultivated to their advantage. Results of the survey are made known in the second of a series of reports on the European industry and trade. Most of the countries which maintained neutrality during the recent hostilities show evidence of stability in exchange, an important factor in the development of American foreign trade.

Holland is less affected by the depressing conditions in the European market for the sale of motor cars than any other country on the continent except, perhaps, Spain. Official reports indicate that money is available and that the American producers control the market to a greater extent than other nations, although the French cars manufactured have a good standing in this country. With the exception of the Spyker plant, which produces about 100 cars per month on the 1921 schedule, there is relatively little domestic production of cars. The Spyker is a six cylinder car selling for approx'mately 20,000 florins.

There are 27 American agencies listed in Holland, as compared with 26 French, 24 English, 19 German, 7 Italians, 3 Dutch, 3 Belgium and 1 Swiss. The simplicity of the American design and the interchangeability of parts with the quick supplying of spare parts are advantages that the European makers do not afford their customers. In the opinion of C. S. Johnston, Commercial Attaché at The Hague, the matter of service is very important and should be developed because the best sellers are those combining the lowest first cost and economical maintenance and operation. He believes that Europe has long been acquainted with the small-bore high-speed motor which has demonstrated to the satisfaction of the buyer that it is not an extravagant fuel user and is the most economical car to own.

Waterways Handicap Trucks

The waterways of Holland have a natural tendency to prevent the development of a large truck business. It is reported that American truck producers who have investigated the situation feel that it will not be worth while to force the market with anything over a 1½-ton truck. The narrow streets and roadways make it impracticable to operate heavy trucks. The emigration to America has stripped many of the farms of their labor supply and, as a consequence, has directed interest to farm machinery.

Tractors and Horses to Meet in Contests

N. I. V. A. Arranges Series of Meetings to Demonstrate Mechanical Economy

CHICAGO, May 23—The National Show and Demonstration Committee of the N. I. V. A. has decided to hold a series of contests between horses and tractors in field operations. There will be three demonstrations, the first of which is scheduled for Fargo, N. D., June 28, 29 and 30. Another demonstration will be held in the Southwest and the third in the Central West, time and location of each to be decided later.

Two shows also have been authorized; one for Minneapolis and the other for Kansas City, provided suitable quarters can be furnished rent free, and provided also that all other suitable and satisfactory arrangements can be made between the local and national committees.

The horse and tractor contest is of special interest and in order that the results of these comparative tests may be unbiased, fair and convincing, the committee resolved that:

"The observations and data for such records be taken by a committee composed of representatives from the American Society of Agricultural Engineers, from the State University either of the State where the demonstration is held or the university of any other State; from tractor manufacturers, from the Society of Automotive Engineers, from the Horse Assn. of America and from the United States Department of Agriculture."

As an inducement to secure the very best horsepower available, it was decided to award suitable prizes to horse owners entering the contest and making the best records on the cost of preparing their land allotments.

The dollars and cents cost comparison between horse power and tractor power in plowing and preparing seed bed as provided in these demonstrations will not take into account some of the most vital considerations in successful tractor operation, especially belt work, but new rules are provided by the committee so that manufacturers of belts and belt driven machinery of any kind, operated with a tractor, are eligible to exhibit at these demonstrations. It is expected that the educational work of belt operations will be among the most interesting features of the demonstrations.

No individual records of tractor performance and no comparisons between individual tractors will be given out for publication by the committee in charge of the demonstration. Each tractor manufacturer, however, will be provided with the record of his own machines.

JANESVILLE BUYS TRAILERS

JANESVILLE, WIS., May 23—The Janesville (Wis.) common council has placed a contract with the Highway Trailer Co. of Edgerton, Wis., for four 2½-ton trailers with dump bodies and hoists as initial equipment of a new municipal garbage collection system. The trailer is a special design known as the Highway Garbage and Ash Trailer, which is now being manufactured in quantities for municipalities. The cost of the four trailers is $7,280, less 25 per cent, f.o.b. Janesville, or net $5,460.

Delaware Law Requires Ownership Certificate

WILMINGTON, DEL., May 23—Under a law passed at the last session of the Delaware Legislature, which becomes effective June 1, a sworn certificate of ownership, with minute details of the car, must accompany every application for a motor license in the State. New forms, in compliance, with this law, have been issued by Secretary of State Alden R. Benson. They require the name of the owner of the car, with his business and home address, also a complete description of the vehicle, under oath taken before a notary.

There is also space on the form for the name and address of the vender from whom the car was obtained. All of this information must be sent to the office of the Secretary of State, in Dover, where it is kept on file. The penalty for making a false statement is a fine varying from $500 to $5000, or imprisonment from six days to five years.

The effect of this law, it is understood, is that every sale of a motor vehicle shall be known to public officers, and it will be kept on file.

After Sept. 1 it will be unlawful to have in one's possession a motor vehicle for which a certificate of title has not been issued.

BAR ACCESSORY INSURANCE

ATLANTA, May 21—The Southern Underwriters' Conference has decided to write no more insurance against the theft of automobile accessories. This action has been taken because of heavy losses on the theft of such equipment as spotlights, motormeters and spare tires. These losses have been general throughout the South. The Southern Underwriters' Conference comprises the States of Virginia, North and South Carolina, Georgia, Florida, Alabama, Louisiana and Arkansas. Practically every insurance company in these states is a member. Insurance now in effect will not be cancelled until it expires.

WISCONSIN ADDS NEW MODEL

MILWAUKEE, May 23—The Wisconsin Truck Co. of Loganville, Wis., engaged for three years in manufacturing motor trucks for general farm and light commercial trucking, has added to its line a larger model produced for several years by the Luverne Motor Truck Co. of Luverne, Minn., with which the Wisconsin company is closely affiliated financially. The larger model is equipped with a six-cylinder Continental motor and has a capacity of three tons.

Inspection to Lower Insurance Losses

Wisconsin Agencies Make Careful Survey of Risks to Prevent Imposition

MILWAUKEE, May 23—In several cities in this section automobile insurance agencies are inaugurating an inspection service as a device to lower the losses of insurance companies, especially on theft and collision coverages. As is becoming known, some companies are declining to write full collision policies. Others are now beginning to limit their liability on theft coverage.

The inspection service being installed varies with different insurance agencies. A typical one operates as follows:

When a car is written for fire, theft or collision, an inspector is sent to see the car and report on it in detail as to condition, number and age of tires, approximate usage, date of purchases, etc. A copy of the report is filed with the assured. If a used automobile is insured, inspection is followed up at least every six months.

The insurance men state that frequently when the owner of an automobile receives the report, insurance is cancelled. An underwriter here said:

"We claim that the insurance companies are imposed upon, especially in cases of reported thefts of tires. The claims always seem to be for brand-new tires. When a claim comes in, under the inspection system, we can refer to our records. Defects of tires are noted at the time of inspection. Radiators are examined. It is a fact that the greatest savings we have made come from cancellations of policies by the insured when they find out that we have a complete report in every detail of the car, tires and all. Losses have been a heavy drain on the companies, and it is necessary to reduce losses or make the rates practically prohibitive."

S.A.E. Discusses Means to Check Theft of Cars

NEW YORK, May 20—The subject of automobile theft prevention was discussed from several angles at the Metropolitan Section meeting of the Society of Automotive Engineers May 19. The opinion was voiced by some that the insurance companies by granting insurance to the full value of the car tended to encourage carelessness on the part of the owner. The advisability of granting insurance for only 75 per cent of the value was discussed.

The car owner is chiefly responsible for most thefts, according to several of the speakers, because of his failure to use the lock and safety devices even when his car is equipped with them. There was also some sentiment expressed indicating that the manufacturers of locks did not always provide enough key changes on their product.

Production in 1919 Dwarfs 1914 Figure

Industry Grows Almost Five Times in Five Years—Michigan Far in Lead

WASHINGTON, May 21—Official statistics compiled by the Bureau of Census reveal the tremendous growth and importance of the automobile industry. Production figures received from 315 establishments in 1919 show that the total output amounted to $2,387,834,000. In 1914, 300 establishments reported manufactures valued at $503,230,000. About 56 per cent of the automobile industry is located in Michigan, as the output of 68 establishments in that state amounted to $1,332,076,000. There were 1,683,938 automobiles produced in 1919, with a valuation of $1,555,129,000, as against 573,039 in 1914 valued at $465,058,000, an increase of nearly three times.

The government figures, which are preliminary and subject to final revision, show that 101,837 trucks valued at $193,351,000 were produced in 1919, as compared with 19,519 trucks and a value of $34,741,000 in 1914. Delivery wagon production totaled 18,122, valued at $16,570,000. In 1914 the production of this type of vehicle aggregated 4391, with a value of $12,750,000. All other types of business vehicles not specified amounted to 955 machines in 1919, valued at $2,283,000, as compared with 262 machines in 1914 with a value of $787,000. In the aggregate there were 120,914 business vehicles manufactured in 1919, with a value of $212,204,000. In 1914 there were 24,172 vehicles valued at $40,278,000.

The total valuation of $2,387,834,000 as given by the Census Bureau did not include, for 1919, 5012 automobiles and 80 trailers to the value of $8,067,562, and in 1914 4258 automobiles valued at $6,296,558, which were reported by establishments engaged primarily in other industries.

Parts Gain Enormous

Comparison of chassis production is impossible because it was not reported separately in 1914, but the 1919 figures showed 192,418, which were produced at a valuation of $181,889,000. The same condition obtained with trailers, which were not reported in 1914. In 1919, 15,606 trailers were manufactured with a value of $6,534,000. The total valuation of bodies and parts for 1919 was $533,068,000.

Segregating passenger vehicles it is found that 1,552,349 machines valued at $1,318,038,000 were manufactured in 1919. Production figures of 1914 showed 543,438 vehicles, valued at $413,696,000. No record was kept of production of roadsters in 1914, but in 1919, 51,360 roadsters were produced, valued at $58,033,000. The total production of touring cars in 1919 amounted to 1,224,347, with a value of $977,411,000. In 1914 the 451,032 touring cars were valued at $345,973,000. Closed cars turned out in 1919 aggregated 156,328, valued at $200,015,000. During 1919 only 10,809 closed cars were produced with a valuation of $21,833,000. All other passenger vehicles manufactured in 1919 amounted to 1216 with a value of $2,056,000.

Public Vehicles Doubled

Classified as public conveyances and known as cabs, omnibuses, etc., the census figures showed 877 machines valued at $3,101,000, were produced in 1919 and 443 machines valued at $846,000 in 1914. Of a total production of 2786 machines valued at $13,619,000 for 1919, there were 391 ambulances valued at $613,000 produced. In the same year there were 759 motorized pieces of fire apparatus manufactured valued at $6,939,000. All other machines manufactured for Government and municipal service such as mail delivery, tanks, patrol wagons, street sweepers and oilers, amounted to 1636 machines in 1919, having a valuation of $6,067,000, as compared with 17 machines and a valuation of $45,000 in 1914.

It is interesting to note that this enormous production of gasoline propelled machines far outstripped electric and steam driven automobiles. Comparison of production statistics shows that fewer electrics and steamers were produced in 1919 than in 1914. In 1919 there were 3034 electrics and 406 steam propelled machines manufactured, as against 4669 electrics and 401 steam automobiles in 1914. The total valuation mentioned for bodies and parts did not include production by establishments engaged primarily in other industries.

Comparative Automobile Statistics, 1919 and 1914

Type	Number 1919	Number 1914	Value 1919	Value 1914
Total (1)			$2,387,834,000	$503,230,000
Passenger vehicles	1,553,349	543,438	1,318,038,000	413,696,000
Roadsters	51,360	(2)	58,033,000	(2)
Runabouts	120,098	81,597	80,523,000	45,890,000
Touring cars	1,224,347	451,032	977,411,000	345,973,000
Closed cars	156,328	10,809	200,015,000	21,833,000
Other cars	1,216	(2)	2,056,000	(2)
Public conveyances:				
Cabs, omnibuses, etc.	1,877	443	3,101,000	846,000
Government, municipal, etc.	2,786	728	13,619,000	3,941,000
Ambulances	391	49	613,000	139,000
Fire department apparatus	759	662	6,939,000	3,757,000
All other (mail delivery, tanks, patrol wagons, street sweepers, oilers, etc.)	1,636	17	6,067,000	45,000

Bodies and parts	......	......	533,068,000	(2)
All other products	......	......	119,381,000	44,469,000

(1) In addition, in 1919, 5,012 automobiles and 80 trailers to the value of $8,067,562, and in 1914, 4,258 automobiles valued at $6,296,558, were reported by establishments engaged primarily in other industries.
(2) Not reported separately in 1914.

BUY TRUCKS FOR CATTLE CARS

WASHINGTON, May 20—By order of the Minister of Agriculture, two motor trucks of the type used during the war were recently purchased from France for hauling cattle for the use of the Brazilian Agriculture College. The bodies of the trucks are covered and closed, each having a capacity for four full grown cows.

To Speed Compilation of Export Statistics

WASHINGTON, May 23—More prompt service by the Bureau of Foreign and Domestic Commerce in publishing statistics of the nation's foreign trade will result in announcements of the detailed figures from two to four weeks earlier than before.

The figures, according to the announcement of the Bureau, will be published in two parts, the first of which will be given out on or about the 23rd of the succeeding month. This part will contain "the figures most urgently needed by the trade and will include imports of merchandise by articles and principal countries and exports of domestic merchandise by articles and principal countries, followed by an index of articles and statements of total imports and exports."

Preliminary statements summarizing imports and exports will be given out within 10 or 12 days after the close of month. This will be from 10 days to two weeks earlier than has been the rule.

The service will be speeded up without additional cost to the Government, the statement sets forth, as a result of some changes in the compilation methods. The Bureau co-operates in this work with the Treasury Department which furnishes the original data.

Austin Creditors Agree to Business Continuance

By Cable to AUTOMOTIVE INDUSTRIES

LONDON, May 21—Creditors of the Austin Motor Co., after a full discussion of its financial position, agreed unanimously that the business should be continued so that a plan can be formulated to put the company on its feet. For this reason they have asked that hearings be indefinitely postponed on the petition for compulsory winding up of Austin's affairs.

Dealers Enter Protest Against Excise Taxes

(*Continued from page* 1127)

upon automobiles is a tax upon modern incomes. Seventy-five per cent of all the cars and trucks outside the Atlantic States are in 37 states which have but 45 per cent of the National wealth."

Because Congress has evinced a desire to protect the farmer, the dealers' organizations mentioned that a tax on motor vehicles "is as much a tax on farm production as would be a tax on threshers, plows, tractors, or farm implements. This burden is felt directly by the farmer in the purchase of motor trucks, and is felt acutely by the farmer when he is forced to pay a 5 per cent tax upon his repair parts."

In recommending the repeal of the excess-profits tax, it was declared that "this form of taxation is a deterrent to the initiative enterprise because in productive years it is nearly impossible to set aside sufficient reserves that all enduring business must have to tide them through periods of financial stress such as we are now experiencing." It was further asserted that in times of rising prices the excess-profits tax leads to the "loading" of prices and extravagance in business management, and at best is always an uncertain factor in price making.

In suggesting a reduction in the higher brackets of the income surtax, the dealers expressed the belief that it would induce capital now in exempt securities to return to industry. It was said, "this return would likewise restore the purchasing and investment power to the individuals thus employed who in turn would be a considerable prospect for the absorption of the tax-exempt sucurities so abandoned."

Should Not Set Standards

Discussing the question of essentiality, the dealers declared: "We do not believe that it is a function of free government to set up standards, arbitrarily, of essential or non-essential industry, nor classification of necessities or luxuries. We believe that in a government such as ours, the government should guarantee to all business perfect freedom of existence, expansion of opportunity, and should permit each individual to make the choice as to what is essential to his own welfare and happiness. What are luxuries for some are necessities for others and we do not believe that it is a legitimate function of government to bestow official sanction upon some and impose official condemnation upon others."

Harper stated that the automobile dealers favor the sales tax provided that it is extended to all commodities. He explained that dealers were convinced that a sales tax would be an ethical and equitable form of taxation for all and would produce the desired and needed revenue.

The N. A. D. A. stressed the necessity for economy in governmental expenditures in order to reduce tax rates. It was suggested that the war debt should be distributed over several generations. They recommended the refunding of the present war debt in such a manner that it will be amortized in installments over a period of 50 years. They declared themselves in favor of a moderate protective tariff.

To illustrate the tremendous amount of money paid in taxes on automobiles other than Federal taxation, the Association pointed out that the only state money that is at all available to match Federal aid funds in highway construction and maintenance is derived from motor or vehicle registration fees.

KANSAS CITY RESERVE TO ACCEPT CAR PAPER

KANSAS CITY, May 25—Governor Miller of the Kansas City Federal Reserve Bank announced after a conference to-day with representatives of the automotive industry that he was willing to have automobile paper accepted as collateral at the Federal Reserve Bank. A general statement on the subject will be made public through the press of the district. This follows the visit to Kansas City by Governor Harding of the Federal Reserve Board and is expected to exert a strong stimulating influence on the industry in this section of the country.

Federal Reserve Head to Address N. A. C. C.

NEW YORK, May 23—The annual meeting of the National Automobile Chamber of Commerce, to be held Thursday, June 2, will be addressed by W. P. G. Harding, governor of the Federal Reserve Board. There has been so much misunderstanding relative to the position of the Federal Reserve in connection with loans to certain industries that Governor Harding is desirous of telling all the facts as they relate to the general credit and business situation.

Another interesting feature of the annual session will be a debate at the truck manufacturers' meeting on the subject, "Which Best Serves the Motor Vehicle Users—A Parts Service Rendered by Dealers or a Parts Service Rendered by Parts Manufacturers?"

SHARON RESUMES STEEL WORK

SHARON, PA., May 21—Announcement is made by Harry W. Torney, recently made president of the reorganized Sharon Pressed Steel Co., that its financial difficulties have been satisfactorily adjusted and that it now is in position to handle production of frames up to 1500 a day. Production is now in charge of Arthur W. Swan, general manager, who formerly was chief engineer and works manager of the Crucible Steel Co.

Harding Says Banks Now Have Ample Funds

(*Continued from page* 1126)

governor of the Federal Reserve Bank of the tenth district.

Governor Miller's speech was short and very much to the point. He said:

"The tenth district was not exempt from the national joy ride beginning in October, 1919. It was called upon to distribute credit equal to its entire lending power. By April, 1920, it had rediscounted and borrowed $10,000,000, which sum will be later increased $35,000,000 from other districts. Lending by this bank had to stop, that our credit be conserved. It was necessary to scrutinize all paper for rediscount. Every class was scrutinized. It is true that in accordance with our responsibility to the general agricultural situation we felt that we should accept the most essential paper.

"The impression prevailed that the Federal Reserve Bank had declared automobile paper not essential. We never suggested to a member bank that it should not freely lend to dealers. We did say to banks, 'You have ample loans on agriculture and live stock to take up your limits. We prefer you send us that and keep the other in your portfolio.' Twelve to fifteen per cent of a bank's portfolio is the usual proportion for rediscount with the Federal Reserve Bank. There is ample room in each bank's portfolio for all the automobile paper it might wish to take. The year 1920 was a hard one with the reserve close to the irreducible minimum. We had a liability to those member banks which had not used our facilities, of $60,000,000. Our responsibility to the district was for the best good of all, including yourselves. If we had not acted in the way we did act, you wouldn't be selling cars now, but the corner seems to have been turned. We can see it more clearly to-day than thirty days ago. If nothing extraordinary happens in the next week or so we can congratulate ourselves that we are fast getting back to normal, and there will be no further scrutiny of paper other than for solvency and desirability."

Two Points Singled Out

This statement was greeted with applause and cheers. Governor Harding, following, urged two points upon the automotive industry interesting in view of prospective relaxation in attitude of member and Federal Reserve Banks toward motor paper. The Governor urged that dealers observe punctiliously the forms prescribed for preparation of paper, and forget their objections to those requirements which many have considered annoying. He also urged that, in the coming period of larger business, care be taken to build substantially, aiming to give real service and not anticipating a boom with extraordinary profits. Governor Harding declared that dealers would congratulate and be thankful to Governor Miller for the masterly manner in which the Kansas City Federal Reserve Bank was handled.

Durant Controls Sheridan Motors

Youngest Line Sold by General Motors

Burke President Under Changed Ownership—Main Durant Plant at Lansing

NEW YORK, May 25—Developments came rapidly to-day in the affairs of Durant Motors, Inc. The two most important were:

That Durant has acquired a controlling interest in the Sheridan Motor Car division of the General Motors Corp.

That the main Durant factory will be located in Lansing and will be under the direction of Edward Ver Linden.

The first formal statement in reference to Sheridan came from the headquarters of General Motors. It said:

"Arrangements have been made by the General Motors Corp. whereby D. A. Burke will purchase the Sheridan Motor Car division and continue it as a separate line."

This announcement brought from the Durant offices the statement that Durant Motors, Inc., had acquired the controlling interest in the Sheridan Motor Car division and that it would be conducted by a $3,000,000 corporation which probably would be known as the Sheridan Motor Car Co. Production will be continued in the factory at Muncie of a car which will be virtually identical with the Sheridan now being made for the General Motors Corp. It is understood that the consideration was in the neighborhood of $5,000,000.

Burke, who spent many months in developing the car, will continue at the head of the company, under the new ownership. He formerly was Buick distributer in Chicago and sold Durant on the idea of turning out at a moderate price a car embodying most of the refinements usually found in higher priced models.

Factory Now Operating

Production began only a few months ago and much attention has been paid of late to building up a dealer organization. One of the prominent distributers selected was Eddie Rickenbacker, famed as an aviator.

This statement was made in reference to the main Durant plant:

"Durant Motors of Michigan, with a capital of $5,000,000, will have its main plant at Lansing, Mich., with a capacity of 40,000 cars a year. E. Ver Linden, who has been responsible for the building up of the Olds Motor Works, will be president and general manager. The plant will assemble and distribute Durant cars between the Adirondacks and the Rocky Mountains under contract and control of Durant Motors, Inc."

Announcement that Ver Linden had joined the Durant organization was made in AUTOMOTIVE INDUSTRIES last week. The ground already has been broken for the Lansing plant and it is expected to be ready for occupancy by Nov. 1.

The report is not denied that T. W. Warner, head of the Muncie Products division of General Motors, soon will relinquish his position to join forces with Durant. His retirement is not expected to involve any change in the present ownership of Muncie Products. The plant of the T. W. Warner company at Muncie, Ind., was acquired under lease by General Motors during 1919, with option to purchase after Jan. 1, 1923. Warner also heads the Toledo-Chevrolet Co., which manufactures transmissions.

Klingensmith Mentioned

F. L. Klingensmith, former general manager for Henry Ford, who now heads the Gray Motor Co., declines to deny reports that he will be associated with Durant with the Gray company as a unit of the Durant organization. He asserts, however, that his company will be in the market at the end of the year with its own car.

R. H. Collins, former president of the Cadillac company, now is spending all his time in the main building of the old Cadillac plant which was purchased from the General Motors Corp. for the Collins Motor Car Co., now being organized. The portion of the former Cadillac plant purchased by Collins contains more than 300,000 sq. ft. of floor space.

There is reason to believe that when production actually is begun by Collins and Ver Linden, they will add to their organizations several of the men who served under them in executive capacities at the Cadillac and Olds divisions of General Motors. It also is understood that Durant already has opened negotiations with some of the most successful distributers of the General Motors Corp.

NASH DECLINES STATEMENT

KENOSHA, WIS., May 23—Charles W. Nash refused to-day either to confirm or deny persistent reports that the Nash Motors Co. would acquire a substantial interest in Lafayette Motors Co. of Indianapolis. Nash himself is president of Lafayette Motors and has a large personal interest in that company.

Distributorships Combined

INDIANAPOLIS, May 24—New distributers in Chicago and Philadelphia were named this week by E. C. Howard, vice-president of Lafayette Motors Co.

Chicago-Nash Co., under the direction of H. T. Hollingshead, will handle the Lafayette in Chicago. A Nash association has also been made in Philadelphia.

Reimported Trucks Throttling Trade

New York Dealers Unable to Meet Prices on Ex-Army Vehicles

NEW YORK, May 26—Metropolitan motor truck dealers are beginning to feel acutely the competition of low priced trucks from the former European war areas offered for sale here by representatives of an European corporation which purchased them from foreign governments for export to the United States. The imported trucks, including several American makes and one or two of European manufacture, are being offered at ridiculously low prices as compared with quotations on vehicles manufactured for domestic trade. The imported trucks are also being advertised extensively.

Dealers in some of the higher priced trucks are losing in some cases four or five, and in a few instances more, sales per month.

Representatives of the European corporation which purchased these war trucks from France and some of the other governments which participated in the recent war bought the vehicles, which are new, and in most cases in good condition except for the electrical equipment, at very low prices. Under the present law they are able to ship them into this country, providing the trucks are of American make, without duty. Along with the American trucks a few new vehicles of foreign make also are being brought here. These necessarily have to pay duty, but their purchase prices abroad were so low that they can undersell American trucks with similar specifications 30 to 50 per cent.

Buyers Look for Bargains

For a time dealers in New York, as well as in some other cities, did not show much interest in the truck reimportation situation, but now that these trucks are being brought into the market in increased numbers and their sales are being supported by vigorous advertising, dealers are realizing that there has been raised up a very serious item of sales resistance. The fact that the present period is one in which a great many buyers are looking for bargains, naturally helps the agents.

Dealers here are looking to the National Automobile Chamber of Commerce and the National Automobile Dealers Association to exert the utmost pressure upon Congress and officials of the Administration to place a duty on these reimported trucks which will force their prices up to the domestic level.

Overland Cuts Down Current Liabilities

Annual Report Shows Reduction of $14,000,000 in Year—Inventory Drops

NEW YORK, May 27—The facts that made it necessary for the Willys-Overland Co. to ask for extension of its bank loans in 1920 were revealed in the annual report issued yesterday. This showed, however, that important progress had been made in marking down current liabilities, as that item at the close of last year stood at $28,868,386, compared wih $42,519,660 at the end of 1919.

Notes payable, including bank loans of $20,985,000, totaled $24,288,653 on Dec. 31 last, contrasted with $30,360,000 the corresponding date of the previous year. Inventories were reduced in the two-year period from $38,716,624 to $35,309,825. As regards the company's bank loans, bankers state that since the first of the year a further reduction has been accomplished.

Net earnings of the company for 1920, after deducting repairs and maintenance of the properties and bad and doubtful accounts, but before deducting adjustment of inventories to market value and losses on investments in affiliated companies were $8,822,152. From this was deducted $2,114,243 for interest, $3,768,264 as reserve for accruing renewals, depreciation and provision for tool replacements, leaving a balance of $2,939,644.

After allowing for preferred dividend requirements there remained a surplus for the $56,146,675 common stock, $25 par value, of $1,750,934, equal to 77 cents a share. This compared with $2.26 a share earned in 1919. After payment of the dividends on both classes of stock there was an actual deficit of $173,166.

In a letter to stockholders accompanying the report, John N. Willys, president, explained that the company's surplus account had been adjusted through the application of extensive depreciation and reserve items on inventory and material accounts.

Operating Condition Good

"It is believed," Willys stated, "that the reserves and depreciation thus taken are sufficient to place the company in a satisfactory operating condition. The effect of the application of reserves and depreciation provided against inventories and materials is to place the company's whole inventory and forward commitments upon the basis of low current market replacement values. In addition to the reserves and depreciation thus taken, a depreciation of $6,931,693 has been taken on investments in affiliated companies, the total of all depreciation and reserves being $26,101,711.

"Readjustment of the company's plant account has been made on the basis of 20 per cent less than the actual sound value determined by the American Appraisal Co. Branch house properties are carried at their book value, $5,961,811, whereas a recent valuation gives these properties a sound value of approximately $10,000,000."

Mr. Willys said the business of the company had increased steadily since the first of the year, resulting in a substantial liquidation and a betterment of cash position. The company's total indebtedness on May 1, he said, was approximately $20,000,000 less than on the corresponding date a year ago.

MITCHELL REDUCES PRICES

RACINE, WIS., May 26—Mitchell Motors Co., Inc., announces reductions ranging from $210 to $260 in the price of its cars. The factory price of the touring model has been cut from $1750 to $1490 and the sedan from $2900 to $2690.

DE PALMA SETS TRACK MARK

INDIANAPOLIS, May 26—Ralph De-Palma, driving the Ballot special in which he will compete in the 500 mile race Monday, broke the track record for 183 cu. in. piston displacement cars on the Speedway yesterday in qualifying for the contest. His average speed for 10 miles was 101.1 miles an hour.

DODGE DOWN FOR HOLIDAY

DETROIT, May 26—Employees of the Dodge Brothers Motor Car Co. were informed when they quit work last night that they need not report again until next Tuesday. The plant will operate two or three days next week.

CORRECTION

Prices on the Matthews light and power plants have been reduced $50 on the 300-watt and 6 kw. plants, and from $3,600 to $2,975 on the 6 kw. plant. It was erroneously stated in the May 19 issue that prices had been reduced $150. The plants are made by the Matthews Engineering Co., Sandusky, Ohio.

Parts Orders Drop in Last of Month

(*Continued from page* 1126)

facturers regarding what course they are going to pursue on the question of prices. Definite and positive announcements in this respect are needed, parts makers and dealers believe.

Even those watching the situation most closely are uncertain about what the next few weeks will bring in the way of business. Conditions are so topsy-turvy there seem to be no precedents to be followed in making preparations. As a consequence, caution is being exercised all along the line in the manufacturing end of the industry. There is no pessimism, however, and the general feeling is that the present decline in business is partly seasonal and partly due to uncertainty about prices.

Goodyear Sees Falling Off

AKRON, May 24—An official statement issued to-day by the Goodyear Tire & Rubber Co. now in control of the banking syndicate which refinanced it says:

"The seasonal spring spurt of the automobile industry has settled back to a less active situation and curtailment of production of automobiles and parts, including tires, seems likely at once."

No definite information has been given out concerning the Goodyear production plans but there probably will be a reduction in the number of employees.

"We are sending out inquiries as to where men are wanted and efforts will be made to steer the men now laid off to these jobs," said the statement.

Goodyear had reached a production of 19,000 tires a day and reemployed nearly 4000 men since March. Other rubber companies in Akron which also had increased production have begun to reduce their forces.

INDUSTRIAL NOTES

Standard Crucible Steel Casting Co., Milwaukee, is planning important improvements and enlargements to its plant, which is widely known in the automotive industries. Plans are under consideration for a new pattern storage and office building, 3 stories, 35 x 120 ft., and the present foundry and core-room will be enlarged and modernized throughout. George F. Birkel is secretary-treasurer and general manager.

Luthy Co., Inc., has acquired the plant formerly owned by Berger & Carter, manufacturers of cannery machinery, Hayward, Cal. The output of the plant is to be 400 batteries a day. Executive offices are in San Francisco.

Rome Wire Co. has opened district sales offices at 50 Church Street, New York, which will be in charge of H. S. Hammond. Manufacturing facilities have been extended at the plants in Rome and Buffalo.

Robinson Carburetor Co., Birmingham, Ala., has been granted a permit to erect a plant for the manufacture of the Robinson carburetor. The company has been operating on a small scale.

H. H. Franklin Mfg. Co., Syracuse, N. Y., is pushing construction on its new manufacturing building and power plant. Both buildings will be completed by Sept. 1.

Motch & Merryweather Machinery Co., Cleveland, has taken over the sale of the Gordon Cam Turning Lathe in Cleveland, Cincinnati, Detroit and Pittsburgh.

Clark-Turner Piston Co., Los Angeles, has appointed Harkness-Hillier, Ltd., Sydney, Australia, as distributor in Australia of its pistons.

Rice-Fern Hub. Co. will move its plant from Marengo, Ind., to English, Ind., where it has two sites under consideration.

Hirsig Sales Co., Nashville, has been appointed southern representative for Multibestos brake lining.

Dyneto Creditors Seek Plan for Refinancing

SYRACUSE, N. Y., May 23—C. Hamilton Sanford, chairman of the creditors' committee of the Dyneto Electric Corp., has sent to creditors a statement of the assets and liabilities of the company as compiled by certified accountants. With the statement is a letter from Sanford discussing a new financing scheme. The letter in part says:

"Shipments have been running at a rate of about $50,000 per month and will continue until July 1. After that date orders are booked that will amount to about $15,000 or $20,000 per month.

"Your committee has asked interests representing a large amount of capital stock to submit to them plans for the refinancing of the company not later than June 1 and upon receipt of any such plans a meeting of the creditors will immediately be advised, providing such plans are worthy of consideration."

The statement of the company as of Dec. 31, 1920, shows current assets of $56,453, compared with current liabilities of $674,782. Included in the company's assets are the inventory figures, $436,515. According to the accountant's calculations the amount should be approximately $43,000 less. Account receivable from R. M. Owen & Co., and investment in Owen unit tools, machinery and development, totaling $458,177, are excluded from current assets.

The company experienced a net loss of $95,977 for the year ended Dec. 31, last, having the balance in its surplus account reduced to $75,617, the statement shows.

Skelton Motors Held by Estate of Founder

ST. LOUIS, May 23—The formal announcement made here early in March that the assets of the Skelton Motors Corp. of this city had been purchased from the late Dr. L. S. Skelton by W. F. Traves of Kansas City, was premature. No change in the ownership of the Skelton Motors Corp. has taken place and no successor to Dr. Skelton has been appointed. The administrators of his estate are looking after his interests in the company.

Traves is in no way connected with Skelton Motors and John A. Schroeder, chief engineer, severed his connection with the corporation a month ago. The only acting officers at this time are W. A. Chapman, vice president and general manager, and Sidney Penniman, secretary and treasurer.

Since the death of Dr. Skelton last January, Skelton Motors has been in process of reorganization. Plans are now being formulated for the furtherance of the business and an announcement regarding them is expected soon.

Havana Show Closes After Successful Run

NEW YORK, May 23—Information just received by El Automovil Americano, the Spanish automotive business magazine of the Class Journal Co., is to the effect that the automobile show at Havana, Cuba, closed after an eminently successful four days. Known as the Feria de Sevilla, the exposition was quietly arranged by Havana dealers with little help from American manufacturers. Thirteen makes of passenger cars, twelve makes of trucks and two tractors were shown in a large tent in the Almendares athletic field and so satisfactory was it that the Havana Asociacion de Comerciantes y Industriales are contemplating the holding of a larger and more complete show.

The car exhibits were Stutz, Studebaker, Singer, Cunningham, Oldsmobile, Minerva, Benz, Paige, Hudson, Westcott, Packard, Chandler and Cleveland. The trucks were Maxwell, Packard, Garford, Benz, Panhard-Levassor, Republic, Ford, Armleder, Delahaye, Latil, Maccar and Mack. The tractors shown were Case and Fordson.

F. WILLIAM GARTMAN DIES

YORK, PA., May 21—The death is announced of F. William Gartman, vice-president of the York Electric & Machine Co.

METAL MARKETS

WITH the state of morbid drowsiness that has come over the steel market becoming more and more pronounced from day to day, the rest cure, which is being prescribed in some quarters as the most sensible treatment, calls for very little restraint on the part of the patient. Up to now automotive demand furnished a fairly sustaining diet, which was all the more beneficial as it was thought that meanwhile other classes of consumers would set their house in order and re-enter the market as buyers. This expectation has proved false, and what automotive demand is now in the market is of so pronounced a hand-to-mouth character as to furnish to producers little of a dependable basis on which to frame operating programs. Here and there one hears advocated as the most efficient cure a major operation to remove with one incisive cut of the knife most of the adipose fat that has clung to steel prices ever since the war. For the time being, however, quotations will in all probability be permitted to stand, which portends one or two conditions. Either the limited demand will be sufficient to allow of the maintenance of a modicum of operations, and, in that event, intensive competition, accompanied by much price cutting, may be anticipated. The other alternative is that demand will drop to so low levels as to make it less costly for producers to shut down than to continue operations. Should there be many such shut-downs, buyers would be confronted with hardships even greater than those encountered in a market in which demand exceeds capacity production. It is, therefore, decidedly to the buyer's interest not to permit his sources of supply to dry up, if he can at all prevent it. The immediate outlook is for drifting prices, cuts under published quotations expressing the individual eagerness of mills to avoid shutting down to maintain operations on a self-sustaining basis. In the pig iron market a much better tone is in evidence. The same is true of those non-ferrous metal markets in which liquidation has been thorough. That further downward revision of steel prices is a prerequisite to its recovery is generally admitted by producers. Wherein they differ is as to the proper time for proclaiming this lower scale of prices. Possibly the course toward which the present drifting market is heading may force the hands of those who hold that price revision should be postponed.

Pig Iron.—While large transactions are lacking, the market, as a whole, is in much better spirits. Automotive foundries are buying in a retail way, but consumers show much more confidence and seemingly would buy much more liberally if conditions in their own trades warranted.

Aluminum.—From what can be learned regarding the probable recommendations of the Committee on Ways and Means with reference to the rates of duty on aluminum under the new tariff law, it is certain that the duty that will be enacted into law will be far below that provided in the Payne-Aldrich law, i.e., 7c. per lb. on aluminum in ingots, scrap and alloys and 11c. per lb. on aluminum plates, sheets, bars and rods. The American producer has been advocating re-adoption of this scale of duties. Consumers have been driving home to the legislators the argument that, if such increased duties protected the American aluminum industry from foreign competition, they would so curtail American consumption that in the end the American producer would be little the gainer by them. Activity in the aluminum market is absolutely confined to last year's contracts.

FINANCIAL NOTES

Westinghouse Electric & Mfg. Co. reports gross earnings from sales for the year ended March 31, 1921, as $150,980,000, an increase of $15,000,000 over gross earnings for the previous year. Manufacturing and selling cost was $138,774,000, leaving $12,618,000 as the net income available for dividends, or 16.8 per cent on the company's capital stock. Included in the cost is $5,315,000 for depreciation and adjustment of inventories.

Stromberg Carburetor Co. of America, in a comparative balance sheet as of Dec. 31, shows total assets of $3,390,301, included in which are current assets of $841,702 for inventory and $109,322 cash and demand loans. Accounts receivable total $242,274. Current liabilities include accounts payable $102,934 and notes payable $150,000. Profit and loss surplus is $2,344,943, and there is $311,954 reserve for depreciation.

Hood Rubber Co. is contemplating the issuance of $3,000,000 to $5,000,000 in notes for the purpose of paying off bank loans and for working capital. As of Dec. 31 the company had notes payable of $3,610,000 as against $4,860,000 at the close of 1919. Current assets at the first of the year were $17,829,206, against which were current liabilities of $10,051,222, leaving net current of $7,777,894.

United States Rubber Co. directors are aiming to reduce bank loans aggregating $50,000,000 on Dec. 31, 1920, by one-half during the current year. The company is not considering any new financing and does not expect to find this necessary. The company has used up practically all of its high-priced rubber and is taking advantage of current low prices to pick up a reserve.

Rolls-Royce of America, Inc., in a comparative balance sheet as of Dec. 31, shows assets of $7,952,502, which includes an inventory of $1,003,699; cash and accounts receivable, $272,026; deferred charges, $385,225; patent rights, trademarks, goodwill, $3,600,000, and interest during construction, etc., $788,-750. The company's surplus is $4,849.

Maxwell-Chalmers Co. stockholders of Class A and Class B stock have been notified by the reorganization committee, which is headed by Walter P. Chrysler, to pay the balances on this stock by June 1 to the Central Union Trust Co. Failure to make the payments will forfeit all rights of purchase under the subscription warrants.

Stevens-Duryea, Inc., in a comparative balance sheet as of Dec. 31, shows total assets of $6,075,394, which include $2,438,565 inventory and $264,054 cash and accounts receivable. Liabilities show a surplus of $1,282,137 and a reserve for contingencies of $243,856.

American-Bosch Magneto Corp. has sold through Hornblower and Weeks and Harriman & Co. $2,500,000 in 8 per cent 15-year bonds at 98½ and interest, the proceeds of which will be used to pay off floating debt and provide additional working capital.

Mason Tire & Rubber Co. has made financial arrangements for building the Western Reserve Cotton Mills Co. for the manufacture of tire fabrics. It has issued $4,000,000 8 per cent cumulative preferred stock and $20,-000,000 common stock in the new company.

Gruber Tire Co., Monticello, Ohio, will increase its capital stock from $50,000 to $250,000, and will change its name to the Monticello Tire Co. H. O. Altenberg of Davenport will be superintendent.

Goodyear Tire & Rubber Co. has deposited $18,000,000 with the Central Union Trust Co., New York, for payment of a credit of that amount extended by New York bankers. This credit matured May 15.

Fisk Rubber Co. has declared the regular quarterly dividend of 1¾ per cent on the second preferred stock, payable June 15.

G.M.C. Merges Sales of Electric Products

NEW YORK, May 25—Announcement was made to-day by the General Motors Corp. that there is no truth in the report that it proposes to sell the Frigidaire Corp., the Sunnyhome Electric Co. and other units not directly connected with automotive products. On the contrary, the sales of the Frigidaire refrigerator will be extended through the sales organization of the Delco-Light Co. of Dayton. The Sunnyhome company will be consolidated with the Delco company. Both of them manufacture light systems, but there are considerable mechanical differences between them. Sale of the Frigidaire through the Delco organization is considered logical because the refrigerator is electrically operated and is attached to a Delco generator.

It is understood to be the intention of General Motors to continue operation of all three plants for the present at least. Both the Frigidaire and Sunnyhome are located in Detroit.

Townsend Bill Kills Spoils, Says Chapin

WASHINGTON, May 24—Opposition to the Townsend highway bill was indicated by Democratic members of the Senate Post Office and Post Roads Committee to-day in their questioning of Roy D. Chapin, chairman of the higways committee of the National Automobile Chamber of Commerce, who advocated abandoning the present system of Federal aid. Chapin insisted that unconnected stretches of roads were a part of the "spoils" system similar to the erection of large post offices in small towns.

Senator Heflin of Alabama devoted his attention to questioning Chapin concerning the farm-to-market roads. It is this feature of the road situation which inspires opposition from representatives of large farm communities. Chapin pointed out that all progressive states were building such systems connecting with county systems, and thus making a most complete farm-to-market route. He strongly advocated research into highway problems because the industry is only in its infancy. Some of the Senators who questioned Chapin asserted that the automotive industry is the greatest beneficiary from the present Federal aid system.

OBENBERGER PLANT RESUMES

MILWAUKEE, May 23—The plant of the John Obenberger Forge Co. of Milwaukee, a concern which is now passing through the bankruptcy courts, has resumed operations by authority of the referee upon the application of the trustee, J. Frank Gerdis.

BANK CREDITS

Written exclusively for AUTOMOTIVE INDUSTRIES *by the Guaranty Trust Co., second largest bank in America.*

NEW YORK, May 28—The local call money market showed a firmer undertone last week with a comparatively light supply of loanable funds. After renewing at 6½ per cent on the opening day of the week, the rate for call money was advanced on Tuesday to a uniform rate of 7 per cent, at which figure it was quoted for the remainder of the week. The firmer tone was in part a reflection probably of the shifting of funds in connection with the Government operations on May 16 and the payments made on subscriptions to the Great Northern-Northern Pacific joint issue. The time money market was unchanged with little activity and few offerings at rates of 6½ per cent to 6¾ per cent, for 60 to 90 days' and 4 months' paper, and 6 per cent to 6½ per cent for 5 and 6 months' paper.

The Federal Reserve system again made substantial improvement in its reserve position last week. The ratio of total reserves to deposit and Federal Reserve note liabilities combined increased from 55.9 per cent to 56.8 per cent, the highest ratio since the summer of 1918. Federal Reserve notes in circulation at $2,767,415,000 marked a decrease of $37,518,000 for the week and were $637,516,000 below the peak reached on Dec. 23, 1920. Gold reserves increased $15,353,000, while total bills on hand declined $187,774,000. This decrease was largely accounted for by a $142,828,000 decrease in bills discounted and secured by U. S. Government obligations. Deposits declined $16,802,000.

A most significant announcement affecting the railroads and indirectly the general labor situation was that of the Railroad Labor Board in making public its intention of revising the wages of about one million railroad workers to take effect on July 1. The extent of the wage cut to be made has not yet been determined and will be announced on June 1 for all wage disputes submitted to the board prior to April 18. Disputes submitted since that date will be heard on June 6, but will be disposed of with the intention of making the decisions effective on July 1, 1921. This decision concerns, in the main, the unskilled railroad employees, although at least two roads had prior to April 18 asked for wage reductions for all classes of workers.

The stock market was unfavorably affected by announcements of further dividend reductions, etc., in spite of the favorable reception given to the decision of the Railroad Board. The Chesapeake & Ohio and the Hocking Valley railroads deferred action on their dividends and several steel companies passed their dividends. In the bond market there was no marked activity except among the foreign issues, where the smoothing out of the foreign situation and the continued rise in foreign exchanges have been exerting a favorable influence.

MEN OF THE INDUSTRY

Fred H. Williams, for the last seven years an executive in the home office of the White Co. in Cleveland, where he was in charge of the general sales department before being made vice-president of the company, has been appointed, at his own request, general manager of the Philadelphia branch. Operating as a part of this organization are branches in Wilmington and Washington.

Myles Bradley, a former Flint, Mich., newspaper man who directed the affairs of the Durant Corp. while W. C. Durant was at the head of the General Motors Corp., has taken charge of publicity for the new Durant organization. Bradley has had a wide newspaper experience in New York State and Michigan.

John M. Robbins has been placed in charge of the sales department of Huffman Bros. Motor Co., Elkhart, Ind., manufacturers of Huffman trucks. He was formerly with Lozier, Chalmers and Fulton truck, and was also president of the company which formerly bore his name.

Roy E. Breeden has been appointed division sales manager for Service trucks in Michigan and northern Ohio. Walter Dix has been appointed to the Maryland-Virginia district; L. A. Poundstone to the Pennsylvania-New Jersey district, and Fred G. Whipple, the California district.

W. H. Hurley has been appointed general sales manager of the McGraw Tire & Rubber Co., succeeding C. E. Pumphrey, resigned. He has been associated with McGraw for some time in several capacities and before joining the company was connected with Ajax.

J. P. Winterson, a ten-year veteran of the automobile business, has associated with the Stutz Motor Car Co. of America, Inc., as special representative. Winterson has been connected with several of the larger automobile manufacturers, including Lozier and Chalmers.

Glenn A. Toaz has resigned as staff engineer at the Cleveland Automobile Co., Cleveland, to accept appointment as assistant chief engineer of the Butler Mfg. Co., Cleveland, manufacturers of a vacuum street cleaner.

Ivor McCulla has been appointed service manager of the Bijur Motor Appliance Co., Hoboken, N. J. He was formerly with Willys-Overland in a technical service capacity, and before that was with Trego Motors, New Haven, and Packard.

Shirley M. Howe, former general sales manager of the Haynes Automobile Co., has been appointed general sales manager of the passenger car division of the Yellow Taxicab Co., Chicago, manufacturer of the Ambassador.

F. M. Goodman, who has represented the Elgin Motor Car Corp. in the Central States for the past five years, has been appointed district manager of all eastern territory. Goodman's headquarters will be in New York.

Harrie R. Williams, director of sales and advertising for the Milwaukee Auto Engine & Supply Co., manufacturers of timers and bumpers, has resigned. After a rest he will announce his plans for the future.

F. Elbert Glass has been appointed sales manager of the Oakes Co., Indianapolis, manufacturers of accessories. He has been with the company eight years as a sales engineer.

J. T. Lawson has been appointed district supervisor in the Chicago district for Maxwell-Chalmers. He has been connected with the industry for a number of years as field representative, branch manager and dealer.

Judd Colwell, for ten years connected with the Goodyear Tire & Rubber Co. in Chicago, has been made Chicago branch manager of the Miller Rubber Co.

Harry W. Anderson has resigned as sales manager of the Templar Motor Corp., Cleveland. His plans for the future will be announced within a short time.

Andrew Scharff has been appointed northwest district manager for the Multibestos Co., Walpole, Mass. His headquarters will be in Minneapolis.

William Mackone Milner has resigned as advertising manager of the Bergougnan Rubber Corp., Trenton, N. J., and will announce his plans for the future in a short time.

W. K. Swigert has resigned as vice-president and general factory manager of the Oakes Co., Indianapolis. His plans for the future are not announced.

Universal Tool Wins in Reboring Tool Fight

GARWOOD, N. J., May 23—The Universal Tool Co., formerly of Detroit, which now has a factory here, has been granted an injunction by the Federal court, restraining the Flinchbaugh Machine Co., of York, Pa., from further manufacture and distribution of the Universal cylinder reboring tool, invented by R. E. Roseberry. The injunction was granted on the ground that patent rights and trade mark had been infringed.

The Flinchbaugh company has notified jobbers that it has discontinued the sale of these tools and that they now are sold exclusively by the Universal company.

Production of the re-boring tool, embodying new features based on original patents granted Roseberry, was begun here Jan. 1 in the new factory. All tools shipped since April 15 have been of the new design, but no advance in price has been made. Business of the company in April reached normal. February showed an increase of 50 per cent over January and March an increase of 102 per cent over February. The plant now is operating on a 10-hour-a-day basis.

REEVES ANSWERS ATTACK

NEW YORK, May 25—General Manager Alfred Reeves of the National Automobile Chamber of Commerce today began distribution for publication of an answer to statements recently made concerning the automotive industry by F. R. Pleasonton, general manager of the Parish Mfg. Co. Pleasonton's attack, which has been published by several papers, and which has since then been given wide distribution by a large Philadelphia advertising agency, made charges of "dangerous inflation" against the automotive industry, says "distribution has been forced on an unwarranted basis. . . . Millions of cars now in use must be abandoned by their present owners," and claims that no income less than $2,000 should support a car. Reeves points out that many of the statistics in Pleasonton's paper are wrong and that his attack is unsound and unjust. The papers committee of the S. A. E. some time ago refused Pleasonton's document as inaccurate.

Austin to Push Sales of Tractor in Canada

LONDON, May 6 (By Mail)—Austin Motor Co. has a plan arranged to supply Canada with tractors backed by a full service organization including oversight of machines by mechanics from the British works. These men will instruct the agents, their mechanics and the owners how to run and manage this particular tractor.

This development is being awaited with great interest by other British firms, and, if successful, will probably be copied by them, for it was reported at a recent inquiry instituted by the Ministry of Agriculture that British tractor makers will have to look more and more to oversea markets if they are to be able to manufacture in quantities sufficiently large to ensure a selling price on a level with those machines made elsewhere.

This information came through before the announcement of Austin financial trouble; therefore it is possible that the plan may be held up; if not abandoned.

The Ruston-Hornsby Co., which holds the British rights in the Wallis Junior (U. S. A.), also has been named in this connection, but inquiries have failed to prove or disprove the report.

BANTAM DEMAND INCREASES

BANTAM, CONN., May 23—Stockholders of the Bantam Ball Bearing Co. were told at their annual meeting that while orders on the books are not as large as those of previous years, they indicate an increasing demand for the products of the company, and also that an ample organization has been maintained to fill all the orders which come through. Thanks to a conservative policy, the stockholders were told, the company is in an excellent financial condition. The following directors were elected: W. S. Rogers, L. J. Nickerson, H. H. Edwards, N. M. Scott, H. L. Schoonmaker, C. D. Heath and J. L. Buel.

ROLLS SIGNS A. J. ROWLEDGE

LONDON, May 9 (By Mail)—It is announced that Rolls Royce, Ltd., has secured the services of A. J. Rowledge for a long term of years. Rowledge was for many years chief designer with the Wolseley Motor Co., Birmingham, and for the past seven years has been chief designer for the Napier company. With the latter firm he was very largely responsible for the Napier aero engines. as well as for the most recent Napier passenger car chassis.

Calendar

SHOWS

Sept. 28 - Oct. 8 — New York, Electrical Exposition, 71st Regt. Armory, Electric Equipment, Machinery and Vehicles.

Nov. 27-Dec. 3—New York, Automobile Salon, Hotel Commodore.

January — Chicago, Automobile Salon, Hotel Drake.

FOREIGN SHOWS

June, 1921—Reykjavik, Iceland, Agricultural Exhibition—Agricultural Machinery—Icelander Agricultural Society, Reykjavik, Iceland.

September—Buenos Aires, Argentina, Passenger Cars and Equipment. La Pabellon de las Rosas. Automovil Club Argentino.

September—Buenos Aires, Argentina, Cars, Trucks, Tractors, Farm Lighting Plants and Power Farming Machinery. Palermo Park; Sociedad Rural Argentina.

September—Luxemburg, Luxemburg, Agricultural Sample Exhibition.

Oct. 5-16—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

Nov. 4-12 — London, British Motor Show, Society Motor Mfrs. and Traders.

May, 1922—Quito, Ecuador, Agricultural Exposition, celebrating Centenary of Ecuador. Automotive Section.

CONVENTIONS

July 4-9 — Mackinac Island, Mich., Summer Meeting Automotive Equipment Association.

Oct. 12-14, 1921 — Chicago, Twenty-eighth Annual Convention National Implement & Vehicle A'ssn.

Nov. 22—New York, Convention of Factory Service Managers, National Automobile Chamber of Commerce.

RACES

May 30 — Indianapolis, International Sweepstakes.

June 3-5 — Reno, Nev., First Annual Nevada Highway Road Race.

June 18—Uniontown, Pa., Speedway Events.

July 25—Grand Prix, Le Mans.

Labor Day—Uniontown, Pa., Autumn Classic.

Twenty-five Entries for Indianapolis Race

INDIANAPOLIS, May 26—Following are the entries and drivers in the 500-mile sweepstakes to be run Decoration Day:

CAR.	DRIVER.
ReVere Special	Eddie Hearne
Ballot Special	Ralph DePalma
Leach Special	Ira Vail
Durant Special	Tommy Milton
Duesenberg Special	James Murphy
Duesenberg Special	Roscoe Sarles
Duesenberg Special	Edw. Miller
Duesenberg Special	Eddie Pullen
Frontenac Special	Ralph Mulford
Frontenac Special	———
Peugeot Special	Howard Wilcox
Talbot-Darracq Special	Andre Boillot
Sunbeam Special	Rene Thomas
Sunbeam Special	Dario Resta
Junior Special	R. J. Brett
Junior Special	———
Peugeot Special	Jean Chassagne
Duesenberg Special	John A. Thiele
Frontenac	Jules Ellingboe
Chicago-Frontenac Special	Percy Ford
Duesenberg Special	Joe Boyer
Duesenberg Special	Albert Guyot
Frontenac Special	C. W. Van Ranst
Frontenac Special	M. E. Headley
Frontenac Special	L. L. Corum

India Presents Field for Rebuilt Engines

WASHINGTON, May 24—A specific need for light internal combustion engines in India for direct coupling to centrifugal pumps, used to carry water from wells, has come to the attention of Trade Commissioner Batchelder. A light engine is desired, similar to the motor car engine, which can be directly coupled with suitable centrifugal pumps and thus save the extra cost of belting, the friction and slip losses. In connection with coupling the pump with the engine an arrangement will be necessary to start the engine light, preventing the water from pumping and thus loading the engine, until sufficient speed has been gained. The average depth of the wells may be assumed as 150 ft. and the average discharge 160 gal. of water a minute. As the water will be used for irrigation the exhaust fumes of the engine will not affect its use for that purpose. Batchelder, who has been advised that this is one of the best fields for American machinery in India, thinks that rebuilt automobile engines might be fitted for such purposes, or that manufacturers might design the exact type of engine that is needed.

Mulford in Paige Makes Chassis Marks

UNIONTOWN, PA., May 20—Ralph Mulford, driving a Paige, broke all records for stripped stock car chassis in a spectacular performance at the Uniontown Speedway to-day. He established new world's records for five miles, 10 miles, 15 miles, 20 miles, 25 miles, 50 miles, 75 miles, one hour and 100 miles. In the run is a new record for one mile on such a course, although the mile and time remain to be chosen, approved and announced officially by the American Automobile Association contest board.

Mulford's record, unofficially, was 89.6 miles per hour average for the 100 miles. He actually made 89.9 in the hour but it is understood that under rulings of the Three A regarding completion of the mile, he can be credited with only 89 miles, flat, for the hour.

The event was under official sanction of the Three A with G. E. Edwards, chairman of the technical committee, and A. H. Means, secretary of the contest board, in direct charge, assisted by Frank H. Rosboro, local representative of the Three A.

Trucks in Philippines Cut Railroad Earnings

SEATTLE, May 23—So intensive has been the development of motor truck transportation in the Philippine Islands during the last year that the Manila Railroad Co. has appealed to the Government for relief, claiming that the automotive carriers are cutting heavily into the profits of the company.

In the annual report of the general manager of the company it is stated that if the truck, operating as a common carrier, is taxed with a view to reimbursing the Government for the wear and tear it occasions to the road surface, plus its proportionate share of the interest on investment in the highway, then the problem is automatically solved.

Service Lack Ties Up Car Usage in Peru

LIMA, PERU, May 2 (By Mail)—Automotive dealers of Lima and other cities of Peru consider that the present is a big opportunity here now for the sale of spare and repair parts and repair materials. Many cars and trucks, not only in Lima, but also throughout Peru, are laid up because of a lack of service facilities. Firms manufacturing standardized parts should endeavor to reach this market in order that these vehicles may be put back on the roads at once.

Efforts are being made to have the road between Lima and Callao repaired so that truck traffic over it may not be delayed. Callao is the port of entrance for imports to Lima and many of the shipments are transported from there by truck. About twenty of the firms most interested in the handling of such shipments have combined in an effort to obtain betterment of the present conditions. Otherwise they are threatened with a cessation of transport.

Preparations are continuing apace for the opening on July 15 of the industrial exposition to be held in connection with the centenary celebration of Peruvian independence. Although there is a market stagnation, several automotive companies, it is understood, will have exhibits. It is suggested that manufacturers of repair and service parts would undoubtedly find this to be a profitable exhibition.

FORT WAYNE PLANTS BUSY

FORT WAYNE, IND., May 21—The increase in business at the plants of a number of local companies indicates that the worst of the depression which has been affecting local companies for some months is past.

The Dudlo Mfg. Co., makers of magnet wire, which started to show increased signs of life several weeks ago, is continuing to add to its forces by recalling former employees. The plant is now operating on a basis of 75 per cent normal. For the first time since the depression started, some of the departments have been operating overtime. This is particularly true of the department making wire for Ford.

THE AUTOMOBILE

VOL. XLIV. NEW YORK—THURSDAY, JUNE 2, 1921 No. 22

S. A. E. SUMMER MEETING

S. A. E. Holds Another Important and Successful Meeting

Semi-annual gathering is well attended and highly profitable. Papers presented are of great educational and engineering value. B. B. Bachman, Standards Chairman, nominated for president.

WITH a surprise attendance—the total reaching 700—the recent meeting of the Society of Automotive Engineers at West Baden Springs, Ind., will be written into the records of the Society as one of the most profitable gatherings. It was anticipated early in the season that the attendance would be rather low compared with recent years, but the meaning of the attendance can be seen by comparing it with that of 1920, which was 757.

The program was an excellent one and the fuel papers and discussions marked an exceptionally high point of interest. An unusually large proportion of the men were present, interested to learn the advances that have been made in engine design and what is indicated by the research that is under way. Apparently most of the engineers in the industry realize the grave task that is before them in working to a higher economic standard. Without doubt the engineers are taking their work more seriously.

The social and sport side of the meeting was excellent. The hotel was commodious and few complaints were registered. The only drawback was the heat and the showers. Fortunately, all comers had experienced a taste of hot weather before leaving home and they were not inclined to blame the Southern Indiana location. The great atrium of the hotel furnished an ample playground on the wet days.

The nomination for president of B. B. Bachman, chairman of the Standards Committee, met with general approval. The other nominees for the various offices were as follows:

First vice-president, J. V. Whitbeck; second vice-presidents — representing Motor Car Engineering, F. E. Watts; Marine Engineering, H. E. Morton; Tractor Engineering, O. W. Young; Aviation Engineering, V. E. Clark; treasurer, C. B. Whittelsey. Councilors, two-year term, Lon R. Smith, C. F. Scott, H. M. Crane. Councilor, one-year term, W. R. Strickland.

This ticket will be voted upon by mail ballot of the membership and the vote canvassed at the annual meeting of the Society in January in New York. The constitution of the Society provides means for naming a second ticket if the regular ticket is not acceptable, but there has never been a contest.

Probably the greatest professional interest of the meeting, was in the paper on Turbulence, by Harry L. Horning, but W. S. James' paper on Elements of Fuel Economy was the subject of much favorable comment and would doubtless have resulted in as much discussion had it not been the last paper at the concluding session.

The Combustion Session

B. B. Backman, nominee for president.

President David Beecroft.

THE combustion session was in many ways interesting and instructive. Grouping together some of the most advanced ideas on what is believed to take place in the combustion chamber of an engine cylinder, the meeting held forth a promise that the highest thermal efficiency possible with the Otto cycle may be realized in the near future.

The session was presided over by Thomas Midgley, and papers by H. L. Horning on Turbulence, C. A. French on Flame, and Sir Dugald Clerk on Cylinder Actions in Gas Engines were presented. While the discussion showed that there are minor discrepancies in theory and in the interpretation of experimental results at the present time, there is, on the other hand, a remarkable unanimity of opinion on the general fundamentals which apply to flame and its propagation in the combustion chamber.

The discussions brought out the fact that the research work covered has produced many practical results. Increase in the thermal efficiency of automotive engines is not only possible, but in view of the information brought out it is clear that we are standing on the threshold of some very important commercial developments.

Horning Discusses Turbulence

Horning, in his paper on Turbulence, stated that since the subject was actively revived a little more than a year ago, considerable interest and experiment has resulted. The paper, which is printed in condensed form below, is the result of a collection of notes gathered from investigation of the subject in the literature covering past work and also from a large number of experiments conducted under the author's observation.

Turbulence hastens the contact of two substances in a semi-liquid, liquid or gaseous state. Le Chatelier and Mallard noted its effect in their classic investigation of flame propagation. Wheeler and Mason noted a doubled flame velocity in a closed tube as compared with a quiescent mixture. Prof. Bertram Hopkinson noted an increase in flame velocity in a closed vessel when a fan was used to promote turbulence, and Sir Dugald Clerk in 1912 showed that where turbulence is employed there is a noteworthy increase in the speed of pressure development. This increase under the conditions of the experiment reaching 150 per cent.

Harry Ricardo has studied turbulence in recent years and determined that with normal timing, gas velocities through the intake valves of from 130 to 160 ft. per sec. give the highest brake m.e.p., whereas velocities of 160 to 180 ft. give the maximum brake thermal efficiency and velocities of from 180 to 200 ft. give the maximum indicated mean effective pressure. Ricardo has also designed a number of efficient combustion chamber shapes to take advantage of turbulence.

Horning also gives credit in his paper to Woodward, Lewis and Canby of E. I. Du Pont de Nemours & Co., the Bureau of Standards and P. S. Tice for investigations along this line.

An examination of a large number of flame photographs indicates that there are four phases of velocity in a tube of uniform cross section. The first phase is known as the phase of first acceleration. The second phase is one of uniform velocity. The third phase is that of second acceleration and the fourth phase is that of a high uniform rate known as detonation.

The first phase represents a condition which, if it were possible to continue it throughout the entire range would result in the highest efficiency. In this phase the flame is blue. In the second phase the flame becomes green. In the third and fourth phases the liberation of energy is so rapid that incandescence of some of the carbon particles occurs and rapid loss by direct radiation takes place. The second phase represents the combustion of the most economical mixtures at loads at and under those giving maximum economy, providing that there is no marked or incipient auto-ignition. This is at nearly full load performance and with lean mixtures in

low compression engines. This phase is not characterized by a roughness in the performance of the engine. The third phase is obtained in an engine having a compression just low enough to avoid detonation at the most economical mixture but running with a richer mixture. This may be also representative of an engine running where the compression ratio is somewhat too high for available fuels. It is typical of the large class of cars built in the past for more volatile fuel. The fourth phase is characterized by very rough performance. In the third phase the flame is yellow and in the fourth it is brilliant white.

Since the usable velocity must not exceed that at the end of the second phase the problem boils down to securing a maximum area of flame in order to increase volume consumed in a given time. In other words, the design of a combustion chamber permitting rapid spread of the flame crest, developing at each successive advance an increasing area of contact with the unburned mixture.

By the use of turbulence in combination with ideal geometric form of combustion chamber exceptional economies can be obtained. There are three points which generally have a temperature above the average. These are the center of the piston, the center of the exhaust valves and various points in the spark plug. Turbulence tends to prevent the layers of gas over these points from reaching the point of auto-ignition.

Where these layers occur in shallow pockets there is less opportunity for turbulence to keep the gases moving and the high temperature of the mixture at these sections must be kept in mind in locating spark points, as it has been proved by many investigators that the spark plug should be placed in such a position as to ignite the hot portion of the mixture during the early stages of combustion when it is relatively cool rather than allow a flame traveling some distance to set this hot portion off by auto-ignition toward the latter part of combustion when temperatures and pressures are high and the maximum of radiant heat is flooding the combustion chamber. When three high temperature spots and a pocket claim the location of the spark plug, it is necessary to compromise, giving preference to that locality which will set off the hot sections in a pocket first and then the mixtures of lower temperature. Generally speaking, after the pocket is taken care of, the spark plug should be as near as possible to the greatest turbulence and the center of gravity of the mixture.

There are three spots where a spark plug should not be placed: at any point remote from a pocket; at any point remote from a hot surface; at a point where it will be washed by the exhaust and the pumping action of the rings.

Two Methods of Producing Turbulence

Turbulence is produced by two fundamental methods based on the means by which the circulation is initiated. The first and most common method is by means of the intake gas velocities. There is a fundamental defect in this method, inasmuch as it depends on a high gas velocity, which means relatively low volumetric efficiency.

Turbulence is produced primarily by the velocity of flow past the intake valves during the suction stroke of the engine, and secondarily through the subsequent flow of the gases on the compression stroke. The flow through the intake valve is at high velocity but discharging into a relatively large chamber the velocity tends to drop abruptly due to the volume of the space and particularly to its shape. The turbulence which may be developed during the suction stroke is particularly susceptible to the dampening influences that generally exist during the compression stroke when the gas is being forced into a smaller space, and at this period the persistency of turbulence is particularly subject to the influence of combustion chamber shape. Whatever the natural direction of the gases, the shape of the head and all parts of the chamber should be such as to introduce no irregularities into the path. The flow during entry into the cylinder should induce a high velocity and symmetrical course of the gases after the valve is closed, this path merely lengthening or shortening, but keeping its general course when the piston is at its various positions. The energy available for turbulence is limited; hence the most regular and undisturbed paths tend to conserve the velocities. The moment of ignition is the moment of utmost importance. Whatever is done to produce or maintain turbulence must be done entirely in reference to the moment of ignition, for it is the turbulence at this instant which determines the distribution of flame throughout the cylinder.

Turbulence Due to Intake Velocity

In engines depending on intake gas velocities for turbulence there is always a restricting influence in the compromise between high turbulence and volumetric efficiency, and this points to a more effective and convenient method of producing turbulence. Fig. 1 shows a design which is due to Ricardo. This design was developed by him after he had observed the very effective way in which the design shown in Fig. 2 handled kerosene in his tank engines with a relatively high compression without a knock. It was almost impossible to make this engine knock on kerosene at compression ratios of 4.75-1. It is obvious that in this design turbulence is set up at the proper moment through the velocity produced by the piston forcing almost the entire cylinder contents past the opening between the cylinder proper and the valve chamber. This opening need not be restricted to produce high initial velocities, for there is no intervening time for the turbulence to die out before the spark passes; in fact the design can be worked out so that the turbulence is reaching its very maximum when the spark passes. In this form the great problem is the flat section between the piston and the cylinder head, which gives opportunity for the flame to run and knock from auto-ignition. From a turbulence standpoint this form is very effective and it can also be made so as to have a very favorable area-to-volume ratio. It is very favorable because of its compactness for an effective spark location. By making the combustion chamber a hemisphere the most compact form possible is introduced.

There is still another way in which turbulence can be produced, namely, by forcing the contents of the cylinder at high velocity through a venturi of small area into the combustion chamber on the compression stroke. Fig. 3 illustrates this for a valve-in-head engine and Fig. 1 for an L-head engine. Fig. 4 illustrates still another development. The fundamental difference between these methods and those met with in conventional systems is, first, that compression backed up by the piston furnishes a much more positive means for causing turbulence than the atmospheric pressure during the suction stroke; second, gives an opportunity for producing a much more general movement of the gases and, third, turbulence occurs immediately before and during ignition, thus obviating its dying out. The defect of these systems is the increase in combustion chamber area and the introduction of thin layers of gas at some points. So far as the main chamber is concerned there can be no detonation, but unless highly stable fuel is used there will be detonation in the shallow sections over the pistons. The main combustion chambers of these forms have a relatively small area-to-volume ratio.

Turbulence produced by piston compressions is the most

effective known for a given speed of engine. The gas must go through two passages, the valves and turbulence orifice, on the suction stroke; therefore, large areas at these points are advisable and permissible to sustain volumetric efficiency. However, because of the effectiveness of the method and the simplicity of flow and high velocities of the mixture at the moment of ignition, it is doubtful whether such high velocities of mixture through the turbulence orifice are needed as have proved necessary when producing turbulence by intake gas velocity in normal types of combustion chamber.

Figs. 5, 6 and 7 are marked *ET* to show points of effective turbulence. The paths shown indicate the major currents in the gas and should be provided for by design. They represent the greatest velocities and should involve a high percentage of the total mass of the mixture. The most effective turbulences are those involving the entire mass of the mixture in a general movement of highest velocity and along one simple course. This involves less loss in velocity and minimizes the eddies which generally may be considered as parasitic turbulence, marked *PT*. Since these eddies derive their energy from the main stream, they impede it. They are also of lower order of velocity and therefore less effective.

In engines of a design depending on intake gas velocities for turbulence the proper combustion chamber is that which follows most closely the lines of flow of the mixture. Such a form is illustrated in Fig. 8. Another form is shown in Fig. 9 in which the path of turbulence is indicated.

Characteristic Turbulence in Typical Cylinders

Fig. 5 shows diagrammatically the general currents in an overhead valve engine of well known design. It is obvious that when the contents are compressed the contending currents will tend to wipe themselves out; this is the reason why overhead valve engines take higher gas velocities to attain maximum brake mean effective pressure, brake thermal efficiency and indicated mean effective pressure. This type is the least effective from a turbulence standpoint. Fig. 6 shows an ordinary flat type of L combustion chamber, the eddy currents illustrating how ineffective it will be. The large area volume ratio makes it ineffective. This type will have low mean effective pressure and thermal efficiency. Fig. 7 is the usual T-head type which must be run at high speed with spark plug located as shown to get sufficient turbulence for a high mean effective pressure and thermal efficiency.

Fig. 8 shows a form of combustion chamber which Ricardo claims to have used on his design of the Mark Webber engine. While the reported results are remarkable we have never attained satisfactory results with the spark plug placed over the piston as shown in his reports. In fact, we always had very severe knocking.

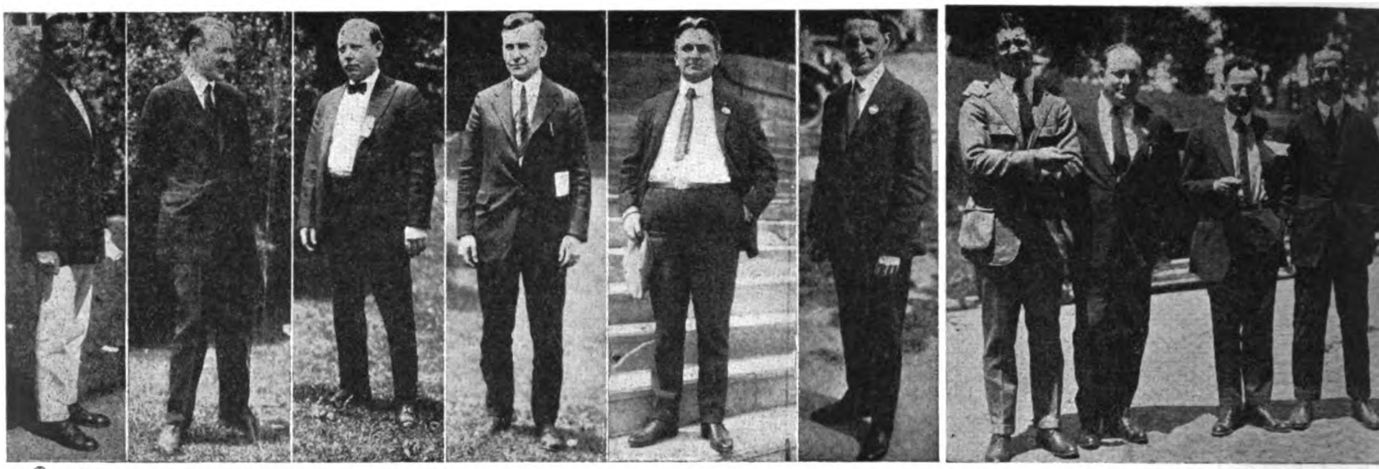
Fig. 9 is a type which has shown good results when the piston and head are like those illustrated in Fig. 8, but as shown here usually requires high speed to give sufficient turbulence for maximum mean effective pressure and thermal efficiency.

Fig. 1, Ricardo L-head type, gives a high turbulence and excellent brake mean effective pressure and thermal efficiency at all speeds and with a very small spark advance.

Fig. 4, the Tyler type, in which the combustion chamber is hemispherical in form, gives excellent results.

Fig. 2, Duesenberg type, is the same as that used in Ricardo's tank engine and the Bugatti aeronautic engine. It is very fine from the turbulence standpoint, gives high mean effective pressure and economy at all speeds and takes a relatively small spark advance.

Fig. 3 shows a turbulent overhead valve type in which



Al. Reeves — O. W. L. Coffin — A. J. Scaife — E. W. Templin — M. L. Heminway — B. G. Koether — R. E. Mackenzie, H. L. Spohn, C. S. Hyman, H. S. Downe.

the piston forces the cylinder contents into the combustion chamber at high speed and thus makes it one of the best types from a turbulence standpoint.

While turbulence tends to cause an increase in the direct heat loss, it decreases the dissociation losses and those due to after burning are brought to a minimum. With a rapid combustion resulting from turbulence it may be expected that the ignition need not be advanced as far as usual. This is found to be true and the spark advance may, all other conditions being equal, be considered an excellent index to turbulence. That is to say, with the same compression ratio, gas velocity, fuel-to-air ratio and volumetric efficiency, the spark advance in degrees may be considered inversely proportional to the combustion efficiency.

We have found it possible to attain with a combustion chamber of L-head type, of the general shape shown in Fig. 8 with cast iron walls, an efficiency of 64 per cent of the air cycle efficiency, as against 54 per cent with a shape approximately like that shown in Fig. 6. With a similar engine of valve-in-head type and at slightly higher compression ratio, we secured an efficiency of 65 per cent of the air cycle efficiency under laboratory conditions with a gas velocity of 170 ft. per sec. and a relative efficiency of 56 per cent with a speed of 110 ft. per sec. and slightly inferior carburetion.

The relatively poor turbulence is markedly shown in the greater spark advance required in a valve-in-head engine, and the high combustion efficiency due to turbulence is shown in the low spark advance in forms of combustion chamber in which the turbulence is highest, such as the high valve pocket L-head design (see Figs. 2, 4 and 8).

We have found a spark advance of 64 deg. necessary in a valve-in-head engine of 4 to 1 compression ratio having a gas velocity of 110 ft. per sec. with a poor carburetion efficiency running at 1000 r.p.m. with a 15 to 1 air-to-fuel ratio.

We have found a spark advance of only 11 deg. necessary on an L-head engine of the high valve pocket design at the same speeds and conditions as specified for the valve-in-head engine above. In this case the relative efficiency was very high, offsetting a low compression ratio.

Conclusion

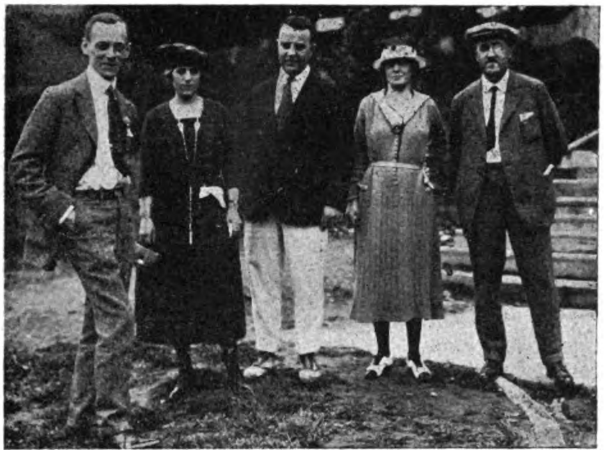
The effects of turbulence upon performance may be summarized as follows:

(1) By developing high turbulence in a mixture it is possible to drive off the surface layers of the combustion chamber and thus force their full contents to contribute to the heat and pressure before the expansion-stroke commences. The fundamental conception of the constant-volume cycle is based on the working fluid receiving all its heat at constant-volume and instantaneously. Neither of these conditions is attainable for obvious practical reasons; however, the wide departure from this ideal with slow-burning mixtures, great spark-advance, low maximum pressures, bad after-burning during expansion, hot cooling-water and exhaust pipes are marked symptoms of low turbulence, and result in low combustion efficiency. Since the air-cycle efficiency is constant in any case, a high combustion-efficiency means a high thermal efficiency and since the indicated mean effective pressure is the product of the indicated thermal efficiency, the volumetric efficiency and the energy content turbulence is directly responsible for increased power.

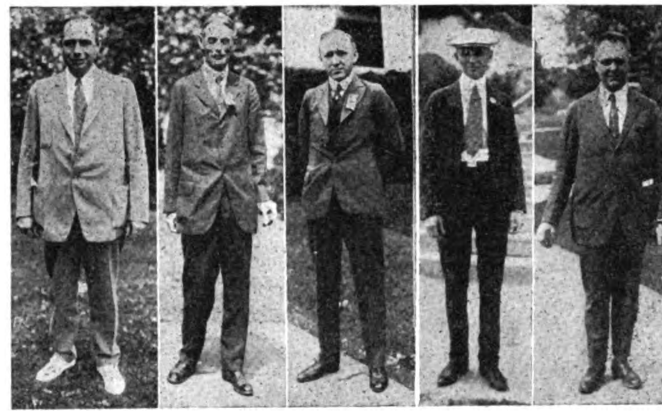
(2) Turbulence tends to hurry the combustion of the entire mixture volume without allowing any part to attain high flame-velocities manifested by preignition, detonations or auto-ignitions within certain limits. These limits are difficult to express, there being no generally accepted scientific method for the purpose. Roughly speaking, the common fuels of 1915 and the spring of 1916 furnished by the Standard Oil Co. of Indiana were such as to allow a cylinder of the general form shown in Fig. 2 to run at a 4.6 to 1 compression-ratio without knock. Whereas, it is impossible to run with this shaped combustion-chamber with the present fuels without a knock at a compression-ratio of 3.7 to 1. With a combustion chamber of the shape shown in Fig. 3 it is possible to run on the present fuels produced by the above-named company with a 4.2 to 1 compression-ratio without knock, whereas with kerosene it is necessary to keep down to a 3.9 to 1 compression-ratio if it is desired to run without knock and without water-injection. These results are on a heavy-duty engine running at 1000 r.p.m., and with chemically correct mixture proportions. It is obvious that so far as compression-ratios are concerned we have not been able, under the above stated conditions, to offset entirely with combustion chamber design the decline necessary in compression-ratios to prevent knocking with present fuels.

(3) On kerosene-burning engines turbulence has made possible a combustion efficiency at fairly high compression-ratios without use of dopes, water or exhaust gases, giving an indicated thermal efficiency of 26 per cent and an indicated mean effective pressure of 80 lb. per sq. in. without special carbureter designs.

(4) Since the fuel of 1915 allowed a compression-ratio of 4.6 to 1, its air-cycle efficiency was 45.8 per cent. The 1921 fuels permit a 3.7 to 1 compression-ratio



B. B. Bachman A. K. Brumbaugh Mrs. H. L. Horning H. L. Horning



A Group of Officers of the Society

E. A. Johnston H. M. Crane A. W. Scarratt J. G. Vincent Coker F. Clarkson

with an air-cycle efficiency of 40 per cent; therefore the decline in fuel value shows a loss of 14 per cent in efficiency due to a necessary drop in compression with old styles of combustion chamber. With new designs of combustion chamber, similar to those shown in Figs. 4 and 6, an air-cycle efficiency of 43.5 per cent is possible, cutting down the air-cycle loss due to fuel to 5 per cent. However, since 1916 we have improved the combustion efficiency from 54 per cent of the air-cycle efficiency to a possible 64, a gain of 18 per cent.

(5) Turbulence makes all high speeds possible by speeding up the flame propagation.

(6) Turbulence makes high speeds possible without an excessive advance of the spark, and with high mean effective pressure and high thermal efficiency.

(7) Due to turbulence, L-head engines of the form shown in Figs. 2 and 6 will be generally superior or at least equal to I-head engines with respect to knocking, all other conditions being equal, including compression-ratio, mixture ratio and volumetric efficiency.

(8) Turbulence has the effect of preventing knocking at a given speed equivalent to one-half a volume in compression-ratio, whereas dopes can improve the compression between three and four volumes, or an improvement of 7 per cent for turbulence against 33 per cent for dopes in air-cycle efficiency.

(9) Turbulence is indispensable to efficient combustion with dopes or without dopes. It is possible to wipe out entirely all the advantage of increased compression allowable with dopes by low turbulence effects.

(10) Flame propagation in combustion chambers is influenced by the following factors in order of their importance. (*a*) The chemical constitution of the fuel molecules. (*b*) Temperature. (*c*) Pressure. (*d*) Turbulence. (*e*) Mixture ratio. (*f*) Compactness and shape of chamber. (*g*) Location and number of points of ignition. (*h*) Some property of the spark. (*i*) Sound-waves in the mixture.

H. M. Crane, in discussion, stated that he has built both L-head and I-head engines with practically identical dimensions. He found that the I-head had just a slightly higher m.e.p. Owing to better turbulence the spark advance in the L-head did not need to exceed 25 deg., while in the I-head engine it had to be carried up to 65 deg. with one plug and with two plugs to 30 or 35 deg. Owing to the big spark advance on this engine it was really firing during the compression stroke.

Crane stated that in his belief the most effective turbulence to utilize is that secured on the compression stroke on the engine and not that due to intake velocity, because the latter soon dies away and is not active enough at the time of firing or near the top of the compression stroke.

Crane also pointed out that the action of the valve passage is to create a whirling vortex action which would interrupt the straight swirl spoken of by Mr. Horning as being desirable. He also stated that in some cases aluminum pistons help relieve detonation because the center of the piston is cooler. Another point noted by Crane is that there is a great difference in efficiency with two spark plugs in the overhead valve engine considered.

Professor Wilson of the Massachusetts Institute of Technology said that he doubted if turbulence greatly increased the number of molecular collisions. Mass motion does not affect the number of collisions, which follow a natural law. He said that in his opinion if anything had any effect it is eddying. On the other hand he thought that the dead pocket theory advanced in the paper is of great interest and value.

Mr. James of the Bureau of Standards stated that the presence of exhaust gases in the combustion chamber has a marked effect on combustion. Increasing the turbulence mixes the exhaust gas with the incoming charge and allows it to cut down the efficiency, while if the inert exhaust gases can be kept stratified on top of the piston and remain at rest conditions are better and there is not so much effect from the dilution of the charge.

In making comparisons between combustion efficiency and air cycle efficiency it must be remembered, said James, that the definition of air cycle efficiency involves eight assumptions. Air cycle efficiency is the efficiency of expansion. If we can burn the charge so rapidly that the peak of the combustion curve is close to the beginning of the combustion stroke and not late, we are getting the best results. The efficiency is dependent upon the fuel as well as on the cycle.

Hugo Gibson said that he was in general agreement with Mr. Horning. He brought up the point that the Knight engine, with its particular type of intake passage and smooth combustion chamber surface, had ideal conditions for smooth turbulence, and consequently had a minimum of eddy or parasitic turbulence. Regarding residual gases the smooth turbulence permitted allows of excellent results in mixing up the fuel, but the picture is spoiled because, he jokingly remarked, "Turbulence does not decrease knocking in the Knight engine because the Knight engine does not knock."

Answering Professor Wilson, Horning agreed with his ideas regarding molecular impacts, but said the object of turbulence is to increase the rapidity of combustion. Turbulence carries the flame into different parts of the mixture, thus creating new starting points for combustion. Since the entire mixture is rapidly inflamed the distance

(*Continued on page* 1157)

Fuel Research Session

MANY of those who attended the fuel research session which was held on Saturday morning regretted the fact that such important papers were scheduled for presentation so late in the meeting that the discussion was necessarily hurried. Many were unable to remain for this session. Nevertheless, the session was highly successful and enlivened by much timely discussion. O. C. Berry presided.

The first paper presented was that on Development of a High Compression Oil Engine by F. E. Ziesenheim, an abstract of which was published in last week's issue of AUTOMOTIVE INDUSTRIES. In introducing the speaker, Berry said that fuel is as necessary to the automotive industry as food is to the human race. Some people believe that the present generation need not worry about the supply of petroleum fuel, but others are of the opposite opinion. Some suggested solutions of the fuel problem are in the nature of a palliative while others are expected to effect a permanent cure.

Thomas Midgley, who opened the discussion, said that we could not hope to obtain more than 20 per cent of the liquid fuel needed for our internal combustion engines from the distillation of coal. He did not agree with the author of the paper that there was little hope for alcohol because it required as much heat to produce alcohol as could be gotten out of it; alcohol could be made with very little heat expenditure. On the other hand, he was not very enthusiastic about shale oil, as the best gasoline that could be made from shale oil would make the worst Mexican oil ashamed of itself. There is, he said, enough cellulose material grown in this country to produce alcohol sufficient to run all our automotive engines on, and it was therefore not even necessary to look to the tropics for the raw materials.

Diesel Pressures Not Higher Than Otto

Hugo Gibson said it was not necessary that a Diesel engine be made exceedingly heavy on account of the high compression pressures. You start with approximately 500 lbs. per sq. in. at the beginning of the power stroke and don't go above it, and this is not very much more than the pressures obtained in Otto cycle engines under full throttle conditions. In fact, under conditions of detonation we go even above it in Otto cycle engines. The problem of starting large Diesel engines can be easily solved by placing a friction clutch between the crankshaft and flywheel and bringing the flywheel up to speed first by means of an electric starter for instance, and then letting in the clutch. If the clutch holds well this method gives very satisfactory results.

W. G. Gernandt said the small high speed Diesel engine has been a hobby with him for some years. He had recently built a single cylinder, two-stroke engine of 2¾ in. bore which had a cylinder head thickness of 5/16 in., a wall thickness of ¼ in., a piston head thickness of 3/16 in. and a flywheel weighing 94 lbs. This engine burned gasoline, kerosene, distillate or fuel oil without change or adjustment. Its speed could be varied from 225 to 2250 r.p.m. by simply varying the amount of fuel injected, and there was absolutely no missing.

In reply to a question Mr. Ziesenheim said that the four cylinder Hvid engine built by the Pittsburgh Filter & Engineering Co. had as good distribution of the power between the cylinders as the regular Diesel engine. Mr. Brewer said that during the war he came in contact with Hvid engines belonging to the Shipping Board and they experienced great difficulty in keeping all cylinders working evenly.

Prof. Berry voiced the opinion that the Otto engine must always be the dominating type because we need the lubricating oil of crude petroleum for lubricating the world's machinery. There is no substitute for this lubricant, and the crude petroleum must therefore be distilled and cannot be burned as crude. Thomas Midgley, Jr., said that the biggest claim made for the Diesel engine was its high thermal efficiency, but substantially equal efficiencies can be obtained from the Otto engine if the compression is raised to a point corresponding to a compression ratio of 7 to 1. This is rendered possible by the use of anti-knock substances. He then gave some characteristics of several anti-knock chemicals, including ethyl iodide, ortho toluidine, di-ethyl celenide, and di-ethyl tolluride. Dr. Dickinson said that we must recognize that there are other lines of industry which demand a portion of the crude oil. In Mr. Ziesenheim's paper it had been shown that only about 28 per cent of the oil produced was converted into gasoline, and it was a mistake to assume that if an automotive engine was produced that would burn any kind of oil up to crude, this would render 100 per cent of the oil produced available for automotive purposes. The shipping interests have recently come to realize the value to them of burning oil under their boilers, with the resultant saving in shipping space. The shipping men can, he said, probably afford under present conditions to pay $10 per barrel of crude.

Mr. Mock observed that the Diesel engine would be limited in its field of application to the marine and tractor fields, to which Mr. Ziesenheim replied that if the Diesel engine took over the marine, tractor and truck end of the automotive industry the fuel situation would be greatly relieved.

The discussion on the Ziesenheim paper had to be cut short on account of lack of time, and the next paper to be presented was that by G. P. Dorris on Eliminating Crankcase Dilution by Manifold Development, and is printed below.

Dorris on Manifold Development

About 1912 the gasoline began to carry heavy ends in such amount that the application of a hot-water jacket around carbureters and manifolds improved the operation of the internal-combustion engine. Then the heavy ends increased up to 1915 and 1916, when a further revision became necessary to provide still higher temperatures than were possible with the limit of 212 deg. supplied by the hot-water jacket. Exhaust-heated manifolds and hot-spots helped to maintain the same degree of efficient operation with the then increased heavy ends of fuel. About 1917 the heavy ends of the fuel sold as gasoline required such an amount of heat to vaporize them that the expression "crankcase dilution" appeared. Now the heavy ends of the gasoline have increased to a maximum boiling point of 446 deg. Fahr. This has made it necessary to go still further in the direction of the heat application to get satisfactory results.

Relative Heat-Absorption of Air and Fuel

In the development of the internal-combustion engine it has become evident that the application of heat to the fuel through hot air is only a mild method of heat application and very detrimental to the volumetric efficiency

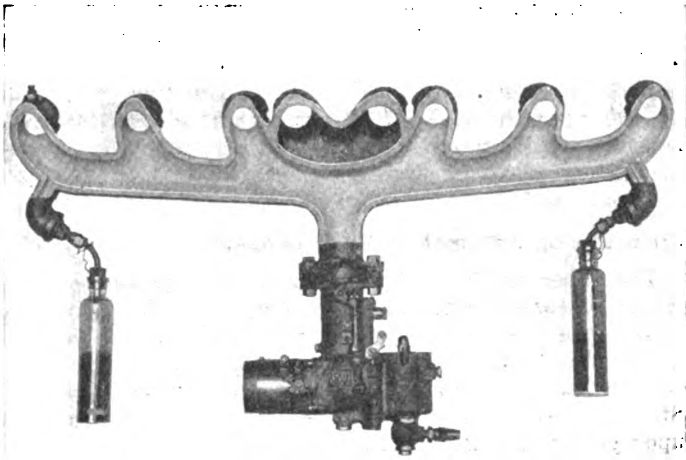


Fig. 1—Admission pipe of a six-cylinder engine in which the two exhaust ports at the center form a hot-spot immediately above the carbureter inlet

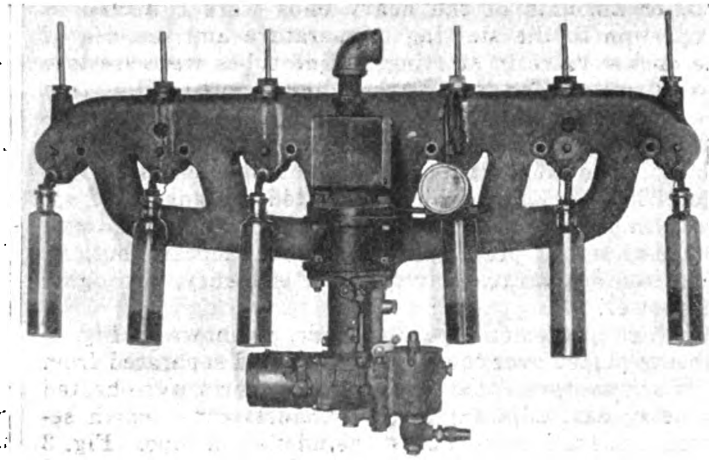

Fig. 2—An improved type of manifold in which the admission pipe is cast integrally over the exhaust pipe, thus securing better vaporizing of the heavy ends

and power output. It soon became recognized that the application of heat through the air was not a method of sufficient intensity to get desired results, and on further investigation it was seen that the direct application of heat to the fuel is a more efficient method as the relative heat-absorption capacity of air and fuel is approximately in proportion to their weights; hence the desirability of the elimination of hot-air jackets and the introduction of direct fuel-heating devices.

To the casual observer gasoline appears to be a definite fixed fuel not readily divided into several grades or degrees of combination of hydrogen and carbon. By subjecting this gasoline or fuel to a vacuum, it becomes evident that the vacuum readily separates the light ends from the heavy and gives a satisfactory gas with a cold engine, which is desirable in starting. Taking advantage of this fact, it is desirable to delay the delivery of the heavy ends of the gasoline until such time as the proper amount of heat can be applied to vaporize and pass them over to the cylinder in a readily mixed fuel for combustion.

Time Factor Required for Vaporizing

As the average motor car engine requires approximately 1/25 sec., at a car speed of 30 m.p.h. to vaporize, compress and expand one charge, it is plain that the time required to vaporize the heavy ends is considerably longer than that available at this rate of operation; therefore it becomes very desirable to provide for delayed passage of these heavy ends so as to supply sufficient heat for their thorough vaporization, to use them as a vaporous fuel and to prevent any liquid fuel, or heavy ends from entering the engine cylinders. The latter has caused disastrous results in crankcase oil dilution and premature wear in the engine bearings.

Fig. 1 represents an admission pipe of a six-cylinder engine, the two center ports of which being exhaust ports form a hot-spot immediately above the carbureter inlet, so that all heavy ends are thrown against the hot wall between the exhaust and admission pipes. The light ends are passed on to the cylinder as a vaporous fuel and the heavy ends vaporized against this hot-spot. This pipe was satisfactory using the fuel which was obtainable from 1917 to 1919. For experiment, the ends of the manifold were tapped for drains, whereby an inspection could be made of the process of delivery of the fuel to the cylinders. In starting the engine at a temperature of 32 deg. Fahr., 2 oz. of liquid fuel was collected in getting the engine warmed up to the operating temperature. The bottles would continue to fill slowly after the engine was warmed up. An inspection of the fuel in the bottles showed a 46-deg. Baumé gravity, while samples taken from the vacuum tank supplying the carbureter showed 68 deg. Baumé gravity. This test proved conclusively that the fuel yielded freely to an evaporation of the light ends, leaving the heavy ends to trail along the bottom of the admission pipe to the two end cylinders. From this it was obvious that a better utilization of fuel could be had under improved operating conditions.

Fig. 2 shows a revised manifold, wherein the admission pipe is cast integrally over the exhaust pipe, whereby considerable additional heat is applied and better vaporizing of the heavy ends accomplished. In making this pipe a pocket was provided between the two center exhausts, which is the lower pipe shown in the illustration, this pocket being an enlargement of the admission pipe and set below the point at which the fuel enters the admission pipe. This pocket collects considerable of the heavy ends on starting. The two center exhaust walls provided heat for vaporization after the engine was thoroughly heated up. Additional pockets were provided below the inlet ports, so that all heavy ends that might be projected over to the engine ports would be collected and their delivery delayed until such time as sufficient heat could be applied to vaporize them. To complete this experiment bottles were connected to these ports and

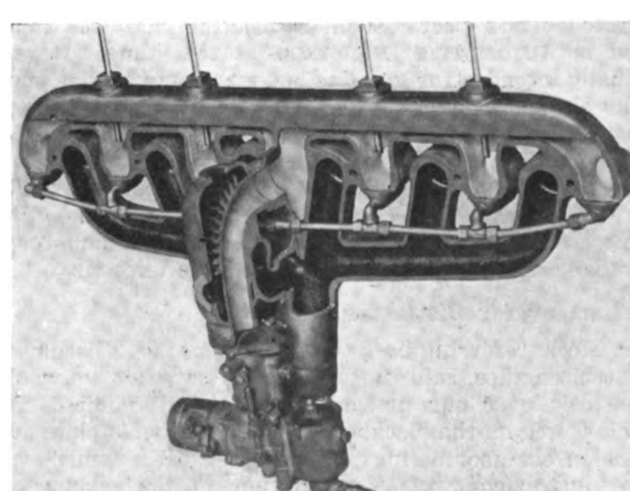

Fig. 3—View of the admission pipe as finally developed. One-half is removed to show the pipe employed to return the heavy fuel ends to the center vaporizing pocket

smaller amounts of the heavy ends were collected in proportion to the starting temperature and the use of the choker valve in starting. Blind tubes were set into the admission pipe down to the point of port-opening into the cylinder so that thermometers could be set into the pockets and the temperature of the gas at the point of admission to the cylinder noted. This temperature averaged 235 deg. Fahr., which permitted the engine to operate in a very satisfactory manner, with very clean combustion and practically no carbon deposit, but, on account of the decreased volumetric efficiency, the engine lost power.

A third admission pipe was made, as shown in Fig. 3, it being placed over the exhaust pipe and separated from it by air spaces so that the admission ports were heated by being cast adjacent to the exhaust ports, which secured a reduction in heat to the admission pipe. Fig. 3 illustrates this admission pipe with one-half removed and four of the thermometers in place. Six were used in the original experiment, but for production reasons the two end bosses have been eliminated. The thermometers show an average temperature, with the changed manifold, of 175 deg. Fahr.

By utilizing a vacuum a large portion of the light ends of the gasoline is vaporized, but the air is not heated or the admission pipe temperature raised unduly.

Figs. 2 and 3 show auxiliary heaters of different capacity bolted to the admission pipe. These heaters are controlled by valves, more or less hot gases passing from the exhaust to them. Fig. 3 shows the admission port pockets with the piping to return all heavy fuel ends collected to the central pocket or vaporizing still where they are stored until sufficient heat is accumulated to vaporize them.

With this type of manifold it has been possible to eliminate crankcase oil dilution completely and effect a reduction in carbonization. The lubrication efficiency has been improved. An improvement has been effected in acceleration and quick starting, and the engine will run at a constant speed with a good torque within 1 min. after starting. A 4000-lb. car has covered 17 miles on a gallon of gasoline in a straight run at 30 m.p.h. In a 1-gal. test, using kerosene as fuel, a car equipped with this manifold made 17.1 miles. These results prove the efficiency of the equipment in preventing the passage of liquid fuel to the engine cylinders.

A. W. Scarratt gave a description of a manifold which he developed for the trucks of the Minneapolis Steel and Machinery Co. This manifold was also referred to by Mr. Scarratt at last year's summer meeting and was illustrated in AUTOMOTIVE INDUSTRIES at that time. It was originally intended for gasoline but was found to give good results also with kerosene and has been used mainly with the latter fuel. On a 3½ ton truck a fuel economy of 6.8 to 7.1 miles per gallon is obtained. An interesting point is that the temperature at the outlet of the manifold is 175 deg. Fahr., with gasoline and 210 deg. with kerosene. The same manifold also works well with alcohol, although considerable heat must then be supplied to the inlet air.

One Remedy for Distribution Troubles

Mr. Mock, referring back to the paper of Mr. Ziesenheim on Diesel engines, said that within a few years we would be entirely over our present distribution troubles. He drew a sketch on the blackboard showing a baffle plate and expansion chamber acting as a fuel separator which was placed just beyond the Venturi tube of the carbureter. The liquid fuel particles separated out due to the low velocity in this chamber, drop onto a hot spot and are distilled off, thus rejoining the air stream. He predicted that when this device is fully developed there will be no need for limiting the manifold cross sectional area. Mr. Horning, referring to Mr. Dorris' paper, said that he had run an experiment in which he collected the unvaporized portion of the fuel from the bottom of the inlet manifold. At 400 r.p.m. he took off 50 per cent of all the fuel fed, and "the engine never knew it." This accumulation measured from 49 to 51 deg. Baume as against 58 deg. for the fuel itself.

Elements of Automobile Fuel Economy

The paper by W. S. James analyzes the power requirements of cars and traces these through to the source of supply, the energy in the fuel, showing where the various losses occur. The six appendices written by S. W. Sparrow, R. L. Wales and H. C. Dickinson of the Bureau of Standards cover the influence of air to fuel proportions upon power and efficiency, metering characteristics of several carbureters, mechanical efficiency of engines at various loads, ignition timing, the various theories of fuel knock and the relative merits of large, low speed and small, high speed engines. Both the paper and appendices will be printed in condensed form in early issues of AUTOMOTIVE INDUSTRIES.

In presenting his paper, James laid stress upon the need for atomization of fuel as an aid to vaporization, and pointed out that change in spark advance is more important with change in throttle position than with change in speed, so far as its effect upon economy is concerned. The character of the spark is also important, especially when combustion conditions are poor.

Little is known at the present time about the rate of energy liberation during combustion, said James, yet this is an extremely important factor.

James laid stress upon the importance, from a fuel conservation standpoint, of taking steps to secure better economy from the many million cars now in use, and suggested that car manufacturers might well advise present owners or assist them in making simple changes which would result in far better economy.

The time available for discussion of Mr. James' paper was so short that but few speakers could be heard.

Prof. Wilson described experiments he has been conducting at Massachusetts Institute of Technology for the purpose of determining the average dew point of commercial fuels such as gasoline and kerosene. This point is easily found in the case of fuels such as alcohol and benzol, which are not blended with other hydrocarbons, but has heretofore been difficult to measure in the case of complex fuels containing several hydrocarbons of various boiling points. The temperatures thus determined indicate that both gasoline and kerosene can be readily vaporized at temperatures well below that of the exhaust gas.

Mr. James stated that the results obtained by Prof. Wilson could be applied in determining the temperature of mixture entering the cylinder. A thermometer in the inlet pipe is usually welted with fuel, and is therefore supposed to record a temperature below that of the mixture.

W. G. Gernandt, who is interested in the development of high compression oil engines drew attention to the fact that many of the troubles caused by the difficulties in vaporization of even so good a fuel as gasoline are avoided in the injection type of engine which uses a much lower grade fuel.

Thomas Midgley, Jr., in discussing the use of indicators for measuring rapid rise of pressure, mentioned in the paper, drew attention to the fact that recent investigations have shown that certain lines of the spectrum change position with pressure change in the burning gas whose spectrum is being examined. This discovery suggests the possibility of using spectrum analysis as a means of determining the rate of pressure rise.

General Research Session

THE general research session, so called, was opened by Chairman H. M. Crane, who read by title only a paper on industrial research by L. A. Hawkins of the General Electric Co. This paper describes methods, facilities and results obtained in extensive research work conducted by the company with which the author is connected.

C. W. Stratford, well known to Society members and other engineers because of his long study of lubrication and lubricants from both the automotive and oil refiners' standpoint, presented a comprehensive outline of problems relating to lubrication which are in need of careful study and require much research work before solution can be anticipated. The following are among the many points of importance which were touched upon in the informal talk which he gave in lieu of a written paper.

The development of more comprehensive and satisfactory methods of determining the qualities of lubricants was mentioned as being a very real and pressing need, from both users' and producers' standpoints. Work in this direction is in progress at the Bureau of Standards (as recently described in these columns) and further work is needed. Lack of standard testing methods covering several known qualities of lubricants makes it difficult to draw intelligent specifications intended to secure uniformity in quality.

The fact that grease is a poor lubricant was emphasized. It is, the speaker stated, only a soapy sponge serving or intended to serve as a carrier for oil which gives it a certain lubricating value, without which it would be practically useless. The desirability of constructing transmissions, axles and other parts in such a way as to use oil instead of grease, and to retain the oil indefinitely was pointed out, and the considerable saving in power and fuel thus realized was mentioned.

The advantages and disadvantages of pressure feed and splash lubrication were touched upon briefly. Pressure feed systems are more positive and can be designed to assist materially in keeping bearings cool, but are inclined to result in somewhat higher oil consumption than splash systems, according to Stratford.

Graphite and soapstone are solids sometimes used for lubricants, but it is very generally agreed that oil is by far the best lubricant.

Lubrication of cylindrical bearings by oil is not facilitated by the use of oil grooves. An oil film once established in a cylindrical bearing without grooves is not difficult to maintain so long as the temperature is kept within reasonable bounds.

Decomposition and oxidation of hydrocarbon oils begin at about 200 deg. Fahr. The best operating temperature for oil depends upon many factors, but in general it is only slightly above atmosphere. Temperatures above 300 deg. Fahr. cause rapid oxidation.

Screens of fine mesh, intended to strain oil passing from bearings, are apt to become clogged and are not necessary if a sump allowing settling of foreign matter is provided and provision for drawing off sediment is made.

There is a wide variation in viscosity as between so called light oils, and the same is true for medium and heavy. Furthermore, there is seldom consistent uniformity in viscosity over considerable periods of time as between oils of the same brand.

Tests of oils under a government or other unbiased authority with results of samples from various localities compared and published might aid in assuring uniformity.

Frequent change of lubricant tends to conserve the life of an engine. Oil drawn off should not be thrown away; 70 to 90 per cent of it can be recovered by blowing with steam after soda ash is added to break colloids, at a cost probably less than 5 cents per gal.

In opening the discussion on Stratford's paper, H. M. Crane said that the difference between splash, pressure and flooding lubrication should be emphasized. At exceedingly high speeds, splash cannot be depended upon for lubrication of the connecting rod bearings, because the centrifugal force is then so great that no oil from the outside can get to the rod bearings. At low speed, even a heavy duty engine can be effectively lubricated by splash. As regards the subject of strainers, a small screen of 70 mesh, which they had been using for a long time, was sufficient to remove a lot of sand (that always adhered to the aluminum castings) and other solid contaminating elements.

James N. Heald said that we have more cause to worry about the oil problem than the fuel problem. There is only comparatively little oil in a barrel of crude. A manufacturer of high-grade piston rings had told him that by the use of his rings he had been able to reduce the oil consumption of a certain car by about one-quarter. He claimed that much oil was being wasted. If we want to save oil, the best way to do it is to produce a first-

Among Those Who Read Papers

class cylinder bore. The high-grade manufacturers are doing this, but not the others. Boring and reaming, he said, do not produce a first-class job.

In reply to a question from Col. William G. Wall, Stratford said that there is little free carbon in a finished motor oil. He had never found more than 2 per cent free carbon in samples of crankcase oil, and where the carbon reached this proportion it was usually due to extra thin piston heads which heated to such a temperature as to cause the oil adhering to them to crack. Col. Wall wanted to know what caused the deposit inside the oil passages of the crankshaft, whether it was heat or the centrifugal force, and what the deposit consisted of. Stratford said that all contaminating elements were probably represented in this deposit and that centrifugal force was the cause of its formation in the oil channels.

William M. Britton said that vendors of asphaltic base oil state that the carbon deposit from this class of oil is of a soft nature and can therefore be removed easily, and the vendors of paraffin base oil tell one not to use asphalt base oil because it disintegrated so easily and gave no end of trouble in forming hard carbon. He wanted Stratford to tell him just what the facts were. In reply Stratford said that some acid-treated oils break up very readily at high temperatures, especially if they contain sulphur compounds. A good test of any lubricating oil is to heat a small sample of it to about 550 deg. Fahr. for 10 min. The carbon deposit is much the same whether the oil is of paraffin or asphalt base. When the oil is poured out of the cup in which it has been heated, the poor oil will always show a sediment, while the good oil will not. Much research still remains to be done before workable specifications for lubricating oil for any particular purpose can be written.

Chase Discusses Clutches

The third paper scheduled at this session was presented by Herbert Chase, the title being "Practice and Theory in Clutch Design." This paper will be printed probably in full in an early issue of AUTOMOTIVE INDUSTRIES. In opening the discussion, Chairman Crane said that our clutches are required to accomplish two very antagonistic things. Owing to the fact that the clutch must be released for brief moments in order to permit of shifting gears, it is necessary that the spinning weight of the driven element be as small as possible; while, on the other hand, the clutch must be sufficiently large to hold under the maximum load and also not wear excessively under normal slippage. It is the spinning weight problem that militates against the cone clutch, as the cone clutch, having only a single friction surface, must be of large diameter. One well-known foreign car that he knew of has a cone clutch that made it almost impossible to shift from a higher to a lower gear without what is known as double clutching; that is, disengaging the clutch and, after a slight interval, bringing it into engagement again for an instant. There is also much misunderstanding of the real function of the clutch brake. A clutch brake is of no service in changing from a higher to a lower gear, as in that case the clutch needs to be speeded up rather than retarded. Crane had a good word to say for the single plate clutch with lubricated asbestos lining. More than 100,000 miles of service of such a clutch had resulted in no appreciable wear.

Prof. Lay said that another pair of conflicting requirements was that in hard pulling you want the clutch to hold without slipping, while, when first engaging you want it to slip, but Crane thought this requirement could easily be met by suitable arrangement and handling of the control members.

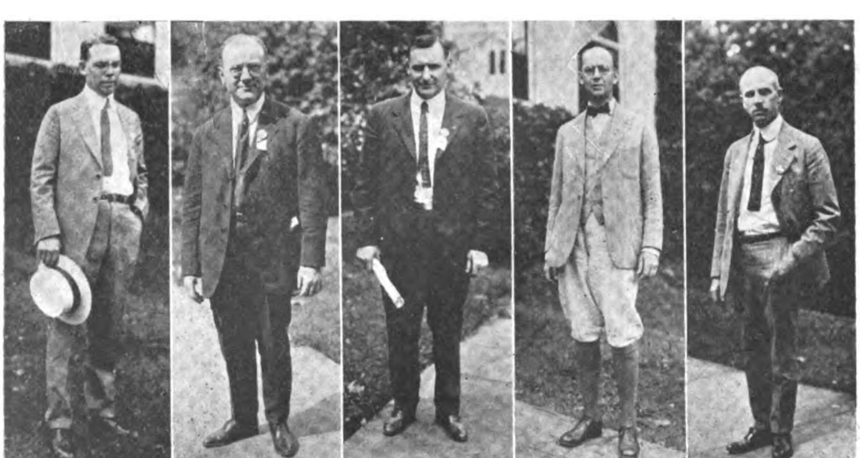
B. B. Bachman complimented Chase on the nature of his paper, saying that it represented an excellent type of research. He added that, in connection with the standards work, he had always insisted on the importance of gathering data from practice. One factor which was not covered in the paper, but is important, is the unit pressure on the splines. If this was obtained for the different clutches surprising differences would be discovered. Another item to which he called attention was the clutch pilot bearing. This bearing is located in an inaccessible place and is sometimes hard to lubricate, and for this reason the use of a ball bearing at this point is, he said, beset with difficulties.

F. E. Moscovics called attention to the coil type of clutch used on the early Mercedes cars. These clutches, he said, were exceedingly compact, yet held firmly when under load, and also slipped well when handled carefully. Crane said his firm repaired a Mercedes 1906 car and in that way gained some experience with that type of clutch. Owing to the small inertia of the driven part the gears shifted very readily—it almost felt as though there was nothing removed by the shifting lever. The clutch had to be handled carefully, however, as otherwise it was likely to grab. Another defect was that if the clutch was allowed to slip for any length of time the wear was very rapid. Other members, including Messrs. Sperry and McGeorge, attested to the excellent qualities and extensive use of this type in various lines of industry.

In closing the discussion Chase said that he believes the need for low spinning weight emphasized by Crane is best realized by the multiple disc design, since sufficient capacity can be had without using friction faces of large diameter or weight.

While acquainted with the Mercedes type of clutch the author said he had omitted reference to it for the same reason that reference to other types not now extensively used had been omitted—namely, that he preferred to confine the discussion to widely-used commercial types.

Prof. W. E. Lay of the University of Michigan presented the concluding paper. It was entitled "Co-operation in Research." He contrasted industrial and technical school research and defined the field for each. The major portion of the paper was devoted to a description of the new testing laboratory of the University of Michigan, which is specially well equipped to make engine and chassis tests as well as tests of a metallurgical character.



W. G. Wall — F. M. Germane — A. D. T. Libby — R. E. Huff — J. E. Hale

The Aeronautic Session

AT the aeronautic session held on Wednesday morning J. G. Vincent occupied the chair. Three papers were presented, one of a somewhat technical and the other two of a commercial or economic character, as follows: Aviation Powerplant Development, by G. C. Mead and L. E. Pierce; Air Transportation and the Business Man, by Col. V. E. Clark, and Need for Federal Control in Commercial Aviation, by S. H. Philbin. Following is an abstract of the paper by Messrs. Mead and Pierce.

Aviation Power Plant Development

Aeronautical engineers unconsciously consider that an engine must weigh less than 2 lb. per hp., and that the fuel consumption is satisfactory if it is in the neighborhood of 0.50 lb. per h.p.-hr. Such an engine rarely lasts more than 50 hr. without a top overhaul, which is equivalent to 6000 miles of air travel. The airplane designer is inclined to believe he must have maximum power and minimum weight at any cost. In this case, the cost is the reduced life of the engine. The commercial requirements involve the use of entirely new factors, since the prime requisites of commercial work are efficiency and durability, which changes the engine design considerably. Our definition of durability is long life. All aeronautical engines must be reliable, but in the past durability has been sacrificed for light weight per horsepower. The weight factor for engines with these requirements becomes at least 3½ lb. per hp. Commercial engines should run at least 16,000 miles without a top overhaul, with a fuel consumption approaching 0.40 lb. per hp.-hr. These constants contrast sharply with those for the military requirements. In this connection it is interesting to compare these figures with those for the Wrights' first engine, which weighed approximately 7.6 lb. per hp. This is a decided indication of the progress that has been made.

The power available from a single cylinder depends upon the dimensions of the cylinder, the speed of operation and the compression ratio. Taking up the cylinder dimensions first, we find that a 5½-in. bore cylinder was practically the limit at the close of the war, which made available some 45 hp. per cylinder and resulted in a large number of cylinders where considerable power was required. The limiting factor for the bore appears to be the reciprocating parts. With large bores, the pistons become difficult to cool in the usual manner. This is not an insurmountable obstacle, since several expedients are known for cooling pistons in other ways. The principal reason is that the power required to overcome the inertia of the reciprocating parts increases rapidly with the increase in the cylinder bore at a given speed. Indicated mean effective pressure is independent of cylinder size, at least so far as our experience to date goes. Therefore, as the cylinder bore increases, the reciprocating weights increase and the speed of the crankshaft must be decreased to permit of a good brake mean effective pressure. At present, cylinders of 7-in. bore are being operated successfully at speeds as high as 1400 r.p.m., with brake mean effective pressures corresponding to those obtained with any of the smaller cylinders. Powers as high as 65 hp. are now obtainable from a single cylinder of this size, a gain of 30 per cent.

Taking up the question of stroke, it has been found that a "square" engine, one having the bore equal to the stroke, makes the lightest possible construction. When the valves are placed in the head, it is very difficult with long strokes to secure sufficient valve area, and still cool them properly so that they will stand up under the temperatures resulting from the high mean effective pressures.

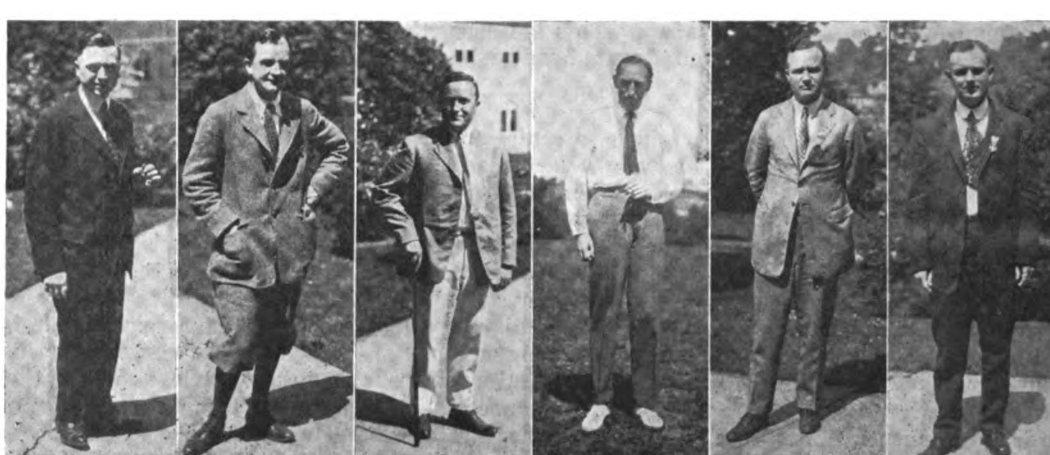
The speed of the engine, or its rate of doing work, is quite important. The limiting factor here becomes the propeller speed. With the pursuit ships it is possible to run the propeller up to 2100 r.p.m., but for commercial work, due to lower flying speeds, it is not desirable to turn the propeller nearly so fast, because of the effect on propeller efficiency. A propeller speed of 1800 to 2000 r.p.m. is considered more or less standard for military work, and from 1000 to 1400 r.p.m. for commercial work. In the case of a dirigible, the propellers turn about 550 r.p.m. The question immediately arises, Why not gear the engine? For military work, no commercially manufacturable gearing has been devised which permits a reasonable powerplant weight per horsepower.

It has been found desirable to increase the compression-ratios as much as possible, to permit the maximum power output of the engines at great altitudes. The maximum compression-ratio from which a gain in power can be secured is 7 to 1. So far, the size of the cylinder does not seem to limit the use of such a compression. Above 5¼ to 1 it is desirable to use some anti-knock substance such as benzol, if it is necessary to operate the engine on the ground under full power.

M. E. P. Possible With and Without Dope

Without dope, it is possible to secure 130 lb. per sq. in. mean effective pressure in water-cooled cylinders, and with dope as high as 145 lb. per sq. in. it follows that we shall be able to produce much larger powerplants with fewer cylinders than formerly, if a demand for them arises.

Great strides are being made in the development of air-cooled cylinders for aviation work. The British report be-



Alex. Taub — Al. Poole — E. B. Ross — J. W. Watson — Thomas Midgley, Jr. — O. C. Berry

ing able to obtain as high mean effective pressures as with water-cooled cylinders. So far, the maximum mean effective pressure which has been developed in this country with large air-cooled cylinders is in the neighborhood of 110 lb. per sq. in. With relatively small cylinders, pressures as high as 125 lb. per sq. in. have been secured. Thus far satisfactory air-cooling has been limited to radial engines. Air-cooling has advantages for an airplane, due to the tremendous differences in temperature under which the engines are forced to operate. It also makes the engine somewhat less vulnerable when used for military purposes. This does not seem to be a very important feature, since most planes that are shot down apparently fall because of fire rather than any other cause. The disadvantages of this type of cooling are that it allows, so far, relatively low mean effective pressures, increases the parasite resistance of the airplane considerably, and does not permit easy temperature-control.

Four cylinders in line are not satisfactory, due to both the power limitations and the vibration. Six cylinders form an ideal combination, since it is possible to obtain powers as high as 400 hp. from this number, and the engines are perfectly balanced mechanically. The weight factor for a six-cylinder engine is from 2.5 to 3.5 lb. per hp., depending upon the service. The limit of the number of cylinders that can be put satisfactorily in one line is eight, due to the torsional vibrations of the crankshaft. The weight of such an engine is about 20 per cent greater per horsepower than for a six-cylinder engine, due to the long crankshaft and crankcase, but for such uses as dirigible work the durability and efficiency of this type are sure to recommend it. Over 500 hp. is available in a single unit of this type.

The V-type eight-cylinder engine is undoubtedly the lightest water-cooled engine known, for the reason that it has the shortest crankshaft for a given power. Weight factors of 1.45 lb. per hp. have been secured from this type of engine.

It has already been proved that eight cylinders of sufficient power to give 400 hp. at 2000 r.p.m., which is a pursuit propeller-speed, do not involve reciprocating parts of sufficient weight to make the vibration serious to the plane structure.

V-type 12-cylinder engines are used considerably for short-distance bombing airplanes, where the engine weight is a factor. Small engines of this type will undoubtedly be in demand for pleasure purposes, just as they are in automobile work. The best weight-factor from a 12-cylinder engine is in the neighborhood of 1.9 lb. per hp. With a given displacement the 12-cylinder engine presents much more exposed cylinder and port area to the cooling water and therefore a considerably larger radiator is required than for a fewer number of cylinders. This increases the total weight of the powerplant and also its head-resistance.

Radial Engines

Serious consideration has been given to radial engines, particularly by the British. The weight-factor for this type of engine is about 2 lb. per hp., when the design is such as to permit the engine to operate satisfactorily for 50 hr. This is practically the same weight-factor as for the V-type eight-cylinder water-cooled engine complete with water and radiator, so that there is really no saving in weight. Moreover, a radial engine of a similar power to that of the V-type eight-cylinder engine has an enormously increased parasite resistance. Radial engines properly balanced are very smooth-running and compact as regards the concentration of weight. The temperature control is very difficult. Fuel consumptions similar to those obtained with water-cooled engines are now possible, but the oil consumptions are just about twice those for the standard water-cooled types. Water-cooled radial engines have been built, such as the Salmson, made in France, but there does not seem to be any particular value in such designs.

In a summary the authors made the following statements: We have not reached the limiting size for any type of engine as regards the maximum power available. No increase in engine performance can be expected unless new materials of construction, new fuels or new cycles of operation are made available. Continued development will refine the practices of the art and result in bettering the life of the engine and the service it renders, rather than its performance. Therefore, increased airplane performance must be secured mainly by improvement in airplane design. Great advance seems to be possible in this direction. One reason for the tremendous powerplants available for airplanes has been the effort to secure performance by brute strength. Absurdities can soon be reached if this trend of development continues. It is certainly worthwhile to consider what can be done with a reasonable-sized power-unit, by altering the design of the airplane. As shown in the last Pulitzer Trophy Race, excessive horsepower is not necessary to secure high speeds. The next few years should see a reduction in the power demanded of pursuit engines.

More Miles Per Gal. of Fuel Desirable

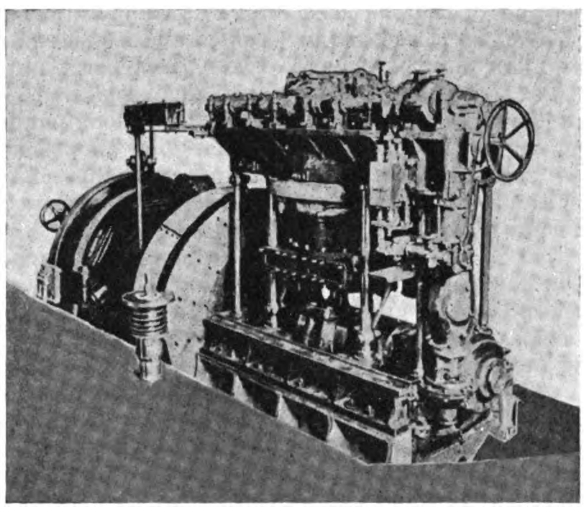
It is high time that attention be given to a most important problem, the fuel mileage obainable from a given airplane. It is unquestionably true that the average person could not afford to operate some airplanes, even though he might be able to purchase one, because of the poor mileage secured from a gallon of fuel. This is an essential consideration for commercial work, due to its effect on the profits of an operating company, and should be given study by the military authorities also, on account of the effect it has upon the quantities of fuel required in case of hostilities. This is, to our minds, the best and most obvious reason why the power requirements for aeronautical powerplants should be reduced rather than increased. It is not commercially possible to build so many power units within a given range. Airplane designers must be satisfied with fewer units, if we are to commercialize the business.

It is believed that the effect of engine dimensions on maneuverability is largely overestimated. The reason that popular comment is so often to the effect that the engine is the most important factor is the fact that there is no ready means by which the aerodynamic qualities of the airplane affecting maneuverability can be thoroughly analyzed and visualized. For similar horsepowers engine type rather than overall size will have the greatest effect on the parasite drag of the fuselage group. The efficiency of the cooling-element design for water-cooled engines is considerably better than that for air-cooled engines. Between practical limits, the effects on the performance of the airplane of variations in the values of engine weight per horsepower, of cooling efficiency, of fuel economy and of altitude performance of the engine are very pronounced. The demands of super-performance in military designs and greatest operating efficiency in commercial designs will require the development of engine types which are most favorable in these respects. The relative importance of the factors involved is governed by the particular service for which the airplane is designed.

Problems of powerplant installation are centered about the need of a close co-operation between the builders of airplanes and engines. The requirements of each system of installation can be met only be acquiring a correct knowledge of what these requirements are and satisfying them fully. A study of the engine mounting in complete detail, developing the truss system to accommodate all of the en-

gine forces involved, both static and dynamic, is a most important requirement in insuring a successful installation. Simplicity and practicality of design and the suitability of the accessory equipment used are most essential in the development of the several powerplant systems. The development of the complete powerplant installation must be made with a view to permitting the greatest possible degree of service accessibility. Only in such a way can the proper mechanical attention be assured for the powerplant. The fact must not be lost sight of that the industry is in a formative period and for this reason we must expect to spend a tremendous amount of time and money in research. We cannot standardize without the necessary knowledge, and we cannot obtain that knowledge without research.

After the presentation of the above paper, Elmer Sperry gave as a volunteer paper an outline of some development work he has been doing in the line of compound Diesel engines for automotive purposes. Just why this was inserted in the aeronautic session was not explained. Sperry referred to the fire risks connected with our present airplanes and cited accidents in the air mail service in support of his statement. He said that in his type of Diesel engine he used what he called bunker oil which actually had fire extinguishing properties. He had recently read of the use of magnesium in commercial work and obtained some samples of the metal. He expected that there was something wrong with the metal and found this to be the case, in that the chips produced in working it were apt to catch fire. Squirting water on the metal would only make matters worse, and to reduce the fire danger, in the factory in Frankfort, Germany, where they produced this metal, they supplied each of the workmen with a pail of the same grade of heavy oil which he used for engine fuel. The pail of oil hung close to the lathes and the oil was for use in smothering an outbreak of flames.



The Supercharged Compound Diesel Type Engine, Described by Sperry.

Sperry showed on the screen photographs, drawings and indicator cards of a three-cylinder compound expansion engine with two 7 by 11 inch high pressure cylinders. The low pressure cylinder is located between the two high pressure cylinders and receives the discharge from these two cylinders alternately. The lower end of the low pressure cylinder is used as a precompressor and forces into the high pressure cylinders a much greater amount of charge than could be gotten in by suction. Owing to this precompression and the resulting supercharging the compression space is not nearly so flat as in the ordinary Diesel engine, and the proportion of surface or cooling area to volume of compression space is therefore much smaller. As in the regular Diesel cycle, nothing but air is drawn into the precompressor and transferred to the compression chamber of the high pressure cylinder. When the piston in the latter reaches the top of the stroke, fuel is injected by a solid injection mechanism in the center of the cylinder head and the mixture ignites spontaneously owing to the heat of compression. The explosion pressures normally attained are in the neighborhood of 900 lbs., per sq. in. These are pressures usually associated with detonation, and Sperry claims to have solved the problem of harnessing the detonation and turning it to useful account.

In the high pressure cylinders the charge is expanded down to about 300 lbs. per sq. in., and it is then transferred to the low pressure cylinder. The two high pressure cylinders are set to explode alternately at equal intervals, working on cranks in the same plane. Using the high pressure cylinders only, Sperry stated, he obtained only 29 hp., while with the low pressure cylinder operating in addition the output was increased to 200 hp. In reply to a question by Dr. Miller as to whether any trouble was experienced from sulphur in the fuel, Mr. Sperry said that it was necessary to keep the exhaust temperature above the temperature of water condensation. Mean effective pressures of from 62 to 75 lb. per sq. in. are obtained.

A number of indicator cards from the engine, obtained with an ordinary piston type of indicator, were thrown on the screen, and emphasis was laid on the fact that the combustion line was absolutely vertical, showing that the combustion took place very rapidly. It is thus shown that one of the objections often raised against the use of the Diesel engine in automotive practice, that the charge won't burn sufficiently rapidly, is not well founded. In the low pressure cylinder the exhaust is through a port at the lower end, which is closed some time after the piston has started on its upstroke, and the gas remaining in the cylinder is then compressed until at the end of the stroke the pressure is substantially equal to the transfer pressure of 300 lb. per sq. in., thus forming a cushion for the low pressure piston and also tending to reduce losses due to clearance in the low pressure cylinder.

Sperry had thrown on the screen a sectional and an outside view of a so-called Diesel aircraft engine built by Dr. Junkers in Germany (views already shown in AUTOMOTIVE INDUSTRIES) and remarked that there were shown two spark plugs in the cylinder wall, which proved that it was not a real Diesel engine. The compression pressure used was only about 250 lb. per sq. in. and there was, moreover, the complication of the double crankshaft. In reply to questions during the discussion Mr. Sperry said that the fuel consumption amounted to 0.42 lb. per hp.-hr. and that the maximum speed attained was 2400 r.p.m.

The engine which Sperry has built and on which the indicator tests were made was of the marine type and weighed about 27 lb. p. hp. He has now agreed with the Government to build a light engine of similar design which is not to exceed 5 lb. per hp., and he hopes to improve upon this figure.

A. D. T. Libby asked what had been the experience with regard to the increase in power by the use of two or more spark plugs in such large cylinders as discussed in the papers.

J. G. Vincent replied that he had had experience with a four valve dirigible engine of 6⅝ in. bore and 7½ in. stroke, a type of engine in which fuel economy was very important. The engine had four spark plugs per cylinder. With all four plugs in good condition the engine would run without appreciable knock, although it was impossible to go beyond a compression ratio of 5 to 1, which was ascribed to a slight variation in the distribution. If three of the plugs were cut out the engine would go nearly through the roof, and it ran about as badly on

Mark Smith, Bert Kelly, Lon R. Smith.

three as on two plugs. This engine operated constantly at 1400 r.p.m.

A member asked why it was that no more progress had been made in this country in the line of water-cooled radial engines which seemed to have reached a high stage of development abroad. To this L. E. Pierce replied that his company (Wright Aeronautical Corp.) is now working on the air-cooled engine problem, and after that had been solved they would take up the water cooled engine. Vincent said that air-cooled engines were made radial because of cooling requirements and not because of aircraft requirements. He also referred to Sperry's mention of the fire hazard and averred that it was not nearly so great as made out by Sperry. The pilots, as a rule, do not dread fire nearly as much as the possibility of being obliged to land in rough, restricted fields. He himself had no more fear of an airplane catching fire than of the same thing happening to an automobile. Engineers now knew how to build airplanes so as to make them practically fireproof; that is, even if a leak should develop in the fuel system the fuel would not accumulate in any place where there was a chance of igniting it. It was true that there had been some cases of fire on the planes of the air mail service, but this was due to the fact that the Post Office, owing to lack of sufficient funds, was compelled to make use of obsolete equipment.

John McGeorge pointed out that while at McCook Field the previous week he observed that the fuel joints on some of the engines there were poorly made, and that this might be one of the explanations of the occasional burning up of planes. It was not a matter of poor design but merely of poor workmanship. Vincent said it had to be remembered that at the Field they got engines for test from all over and that some of these naturally were somewhat crudely built. But before they were put into planes they were always given extended block tests.

Mr. Caldwell said that what we wished to commercialize was not so much the art of flying as the aircraft industry. If it were possible to develop a good pleasure airplane it should not be difficult to find an extensive market for it. He referred to the possibilities of the helicopter, which does not require a big field to start from and land in, can rise to a considerable altitude in a few minutes and is much less unwieldly than a plane. The French were doing development work on helicopters, but had not to date achieved any very notable results. Col. Clark, the author of one of the papers of the morning, later said that he did not think highly of the possibilities of the helicopter. Its stability must of necessity be rather uncertain, not much speed in a horizontal direction could be expected, and there would always be a considerable element of danger if the engine should stop accidentally while the helicopter is in flight.

In Col. Clark's paper the possibilities of getting capital to seek investment in aeronautic enterprises were discussed and it was shown that the prospects were not very rosy. This point was taken up by Fred Moscovics, who said that capitalists should be appealed to to help the movement along on patriotic grounds without any particular view to profits. It had been the fact throughout history that those nations which had the most advanced system of transportation also led in culture and in civilization. He had spent the winter on the Pacific Coast, where there was more flying than in any other part of the country, and he gave some figures as to the time that could be saved by the use of airplanes over different routes. Seattle and San Francisco are 800 miles apart and the trip by railroad takes more than a day. The aerial distance is much shorter than the distance by train and the air trip can be made in about 8 hours. Vincent agreed that commercial aviation had the best chance where other means of transportation are comparatively poor.

A representative of the Air Service stated that they had recently developed a method of predetermining the static thrust of a propeller of given dimensions; that is, the thrust exerted by the propeller when the airplane is at rest and the propeller is being revolved at any given speed. It was found that there is a certain relation between the thickness of the blade and the thrust. The newly discovered method permitted of calculating in advance the horse power which a propeller will absorb at different speeds. The usual ratio between thrust and horse power was 7. The thrust varied as the square of the revolutions per minute, and by increasing the diameter of the propeller and at the same time reducing the speed of revolution to keep the strain due to centrifugal force constant, the thrust ratio could be increased to 10.5 to 1. He was of the opinion that eventually the propeller would be used in landing. In traveling over the country he had observed large districts where it would seem almost impossible to construct landing fields for airplanes, and yet birds landed there every day. When a bird lands it first comes down at considerable speed and then, just before touching the ground it flaps its wings, that is, it exerts considerable power, which enables it to land in a comparatively restricted space.

Col. Clark, referring to a statement by a previous speaker, that one of the ways of getting cities to provide landing fields was to give them an air mail service, said that he was not sure that such an inducement would have much effect. Salt Lake City, for instance, voted an ap-

(Continued on page 1161)

The Combustion Session

(Continued from page 1147)

the flame must propagate itself is greatly decreased, hence detonation velocities are not reached.

Replying to the remarks on the advantages of the Knight engine from the turbulence standpoint, he stated that he agreed in this and that there is apparently but one disadvantage to the Knight engine, and that is the location of the spark plug in the pole of revolution of the stream of turbulence and up in a chamber out of the way. The turbulence is so good, he said, in these engines that notwithstanding the low m.e.p. the fuel economy is good. The reason for this is that the turbulence makes up for the loss of compression, and in a measure acts as its equivalent.

C. A. French in presenting his paper on flame, printed in last week's issue of AUTOMOTIVE INDUSTRIES, advanced several interesting theories, some of which were accepted as a step in the development of present knowledge on this subject and others which were questioned by the members. It will be recalled that the author reached the conclusions that to burn heavy fuels with a blue flame it is desirable to 1. Thoroughly vaporize fuel. 2. Retard speed of oxidation. 3. Crack opaque vapors before ignition by use of radiant heat. 4. Raise compression and use reasonable excess of air. 5. Ionization to prevent ignition. 6. Induce great turbulence. 7. Destroy reverberatory action of combustion chamber walls. 8. Eliminate pockets in the combustion chamber. 9. Locate spark plug in exact center of combustion chamber.

A written discussion by O. B. Zimmerman made the point that we must correct our fundamental theories on what actually occurs in the combustion chamber if we are going to perfect our engines. French's paper, he said, helps us to visualize flame propagation and to realize the effects of changes in the mixture, shape of the container, etc. It will also help to bring home the point to refiners regarding the need of a more uniform liquid fuel.

He stated that we are not far short of the time when the molecular structure of the fuel can be commercially rearranged to provide us with a better fuel. Brewer added that combustion should be so rapid that it should be complete before the piston has traveled 1/10 of its stroke.

Prof. Wilson disagreed with French in his ideas of the molecular and atomic structure of the fuel and showed by models what is generally recognized as the structural form making up the molecule of fuel. Such a conception, he stated, is as necessary a fundamental to the chemist as a true working drawing is to the engineer. He stated that all atoms do not occupy the same space as French contends, but may vary in size in the proportion of 1 to 32. From past research it is known that molecules are tied together in different ways and have different structures. He showed by means of models the construction of hexane, and the benzine ring. With the straight chain construction he stated that the hydrogen burns first and the carbon on the free ends only after hydrogen is combined.

In the absence of Sir Dugald Clerk, his paper entitled Cylinder Actions in Gas and Gasoline Engines was presented in digest form by Prof. Daniel Roesch. Brewer reviewed at length the work done by Sir Dugald. He stated that in 1906 there was a marked revival in research work on internal combustion engines. The complete theory of the thermo-dynamics of internal combustion engines was largely developed in the few years around that time. Brewer stated that the United States has now outstripped Europe in automobile engine research. No discussion was given of Sir Dugald's paper. As Chairman Midgley laughingly put it, "No one felt capable of going up against Sir Dugald on these matters."

Highway Transport Session

IN the absence of H. W. Alden, the highway session was presided over by President David Beecroft. The important work of the highway engineer in developing better and more enduring roads was discussed in papers by A. T. Goldbeck of the United States Bureau of Roads, and C. J. Tilden, engineer of the Highway and Highway Transport Educational Committee, the latter paper being read by Albert Reeves of the National Automobile Chamber of Commerce. The large attendance at the meeting indicated the interest of the engineers in this subject.

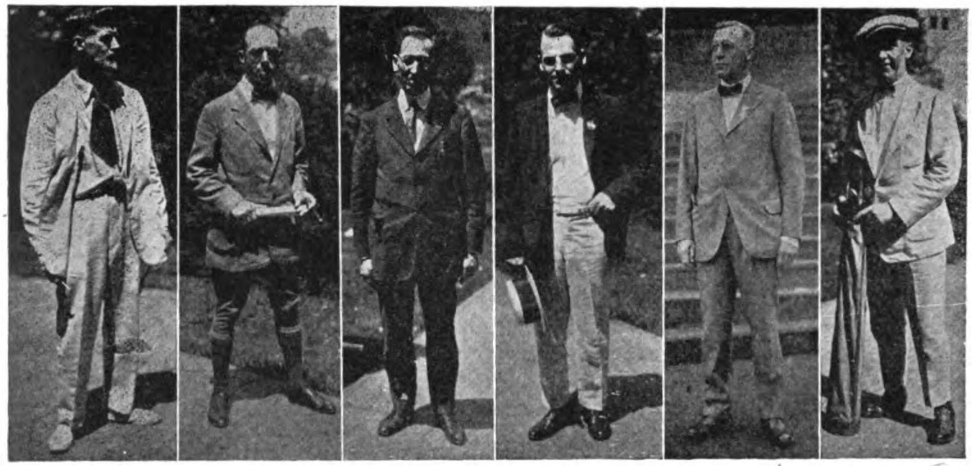
A. T. Goldbeck made the point in his paper that the ultimate consumer does not care who gets the money or how the results are accomplished as long as his transportation bill is as low as it is possible to make it. He stated that the cost of road construction and maintenance must be reduced, and his remark that there is something wrong "when roads disintegrate in two and sometimes in one year" was heartily agreed with by the engineers present.

The author made clear the point that the best highway is the one which carries the greatest amount of traffic for the least amount of money. Another point which he emphasized and dwelt upon as the main issue is that the highway and the vehicle should be mutually suited to each other. He stated that weights and speeds of vehicles are now limited because vehicle construction and road construction are not balanced to meet the requirements of one another.

Goldbeck stated that in his opinion the truck should be designed to meet the limitations of road construction in the same way that the railroad engine is designed to meet the load limitations placed on railroad track. In order to reduce the unit load on the roadbed and on the track the railroad engine has more than four wheels. In the same way the possibilities of a greater number than four wheels should be considered by the truck engineers as a real step in the way of highway conservation. Goldbeck stated that he did not wish to go on record as actually favoring the multiple-wheel vehicle, but that he did consider that the merits of this type of construction should be given very careful consideration, taking the angle of road life as one of the dominant factors.

In speaking of the actual construction of the road, the author stated that the subsoil formation is of the highest importance, as the load is really transferred to this, and when the load exceeds the capacity of the sub-base the road is sure to disintegrate, because this permits the surface to break up.

Another factor in the situation is that of tires. Goldbeck stated that as far as the sub-base for the road is concerned there is little or no difference in the solid or pneumatic tire, as the loading of the road per square inch of ground contact is about the same. In other words, relatively there is an extremely high unit load transmitted to the sub-surface, regardless whether the truck is pneumatic or solid tired, and there is a strong possibility that the multiple-wheeled vehicle will provide sufficiently decreased unit load to give a marked difference in road life.



H. C. Gibson — C. T. Myers — R. E. Northway — H. C. Buffington — E. L. Apperson — E. L. ("Casey") Jones

N. C. Cramer, Albert Champion, E. O. Christiansen

Goldbeck stated that he hoped that the engineers would co-operate with the government department in working out the problem of what is the best road and what is the best way to design a vehicle, so that combined cost of road and vehicle would result in the least possible expense to the consumer.

Russell Hoopes, in the discussion, asked what had been found to be the effect of high and low unsprung weights. In answering this the author stated that there is a slightly noticeable difference in road wear in favor of low unsprung weight, but that as far as the actual vehicle produced is concerned the difference is so slight as to be unimportant. B. B. Bachman brought up the point that trucks as now designed are for the purpose of meeting road conditions as they now exist. Better roads, he stated, would undoubtedly have a material effect on the design of trucks were these roads to be sufficiently universal to represent average conditions. The object of the truck as well as the road is moving merchandise at the lowest possible cost. In this, Bachman pointed out, the road is a considerable factor, as has been shown by tests over the roads. He stated that fuel consumption on one particular run showed a noticeable difference in the miles per gallon fuel consumption of the trip in traversing different highways. In other words, the question of getting the greatest amount of mileage per gallon per ton of product carried must be considered from the road standpoint as well as that of the truck.

R. E. Wilson asked if the pneumatic tire did not help reduce impact on the subsoil. To this the author replied that there was no difference of importance noticeable in their observations, but that unit loads are too high on the big capacity trucks, and it is for this reason that he is looking for more careful examination and possibly for some important developments in the line of trucks with more than two driving wheels.

F. E. Moscovics stated that the suggestions of Goldbeck should be followed, and that the engineers who are members of the S. A. E. should make it their business to co-operate with government road officials to so design their trucks that the life of the road and the cost of transportation will be a minimum. At the request of President Beecroft, Moscovics put his suggestion in the form of a motion to the effect that it was the sense of the meeting that the members of the Society should co-operate with the government highway officials with a view to getting together on the design of both trucks and roads to the end that the highest possible transportation efficiency may be realized. This motion was passed unanimously, and a working committee will be appointed. In closing the discussion Goldbeck expressed his appreciation of the action taken by the Society in designating its intention of naming this committee.

"Transport Engineering Education" was the title of a paper by C. J. Tilden. In this, the necessity for educating, through our universities, men capable of intelligently spending the hundreds of millions appropriated for road construction was pointed out. Before reading the paper Reeves stated that the automobile business has two menaces to-day—unfair legislation and poor roads. He said there are 2,500,000 miles of road in the country, only 10 per cent of which are improved.

Standardization Session

THE Standards Committee session was the first of the meeting and the attendance was surprisingly good and those present stayed well until the finish. Under the direction of B. B. Bachman, chairman of the Standards Committee, the program was conducted with dispatch and the comment kept to the subjects in hand. Chairman Bachman also showed a grasp of the parliamentary difficulties that might involve the procedure and kept things moving by avoiding any pitfalls that might be hidden in the motions, rather than by untangling them later. His run of good-humored comment kept the audience interested despite the severe heat in the ball room of the hotel, which served as the meetings place.

The report of the Standards Committee, the bulk of which was published in AUTOMOTIVE INDUSTRIES for May 19, was adopted, except in certain particulars mentioned below, in the form presented. This report, in the amended form, was later approved by the Council of the Society. It will now be submitted to voting members of the Society in a letter ballot, and if favorably acted upon will become standard or recommended S. A. E. practice.

The entire truck division report incorporating recommended practice for body installation dimensions and motor truck front hubs, was unanimously adopted without discussion. This report, looked upon as the most important of the entire standards work of the year, was reserved until last. When complete silence greeted the call for discussion and a hearty unanimous aye, answered the request for a vote, the members present broke into applause. Considerable interest is being displayed in the next step along the line of recommendations for preferred practice in front hubs for passenger cars.

Clutch Release Type Thrust Ball Bearings

W. R. Strickland read the report of the Ball and Roller Bearings Division, which covered recommended practice regarding clutch release type thrust ball bearings. The dimensions standardized are the bore, width and ball diameter, the outside diameter being left open, owing to divergence in present practice and to the fact that standardization of this dimension is not very important. All the dimensions are given in inches, which is in accordance with the practice of the makers of 80 per cent of the clutch release type bearings now manufactured. The report was adopted as presented.

Roller Chains

W. F. Cole read the report of the Chain Division. This covered two items, viz., a new system of numbering for chains of different pitch, roller diameter and width, and a standard form of roller chain sprocket tooth. This section of the report was adopted as read. There was considerable discussion on the proposed new sprocket tooth form. M. C. Horine objected that the new sprocket form was still in the experimental stage, and that it should not be given the dignity of an S. A. E. standard until it had been thoroughly tried out in practice.

H. S. Pierce of the Link-Belt Co. replied that his company had used a form of sprocket tooth very closely approximating that recommended since 1908, and had found it very satisfactory. The tooth form, therefore, was not experimental. W. F. Cole of the Baldwin Chain & Mfg. Co. said that his firm had cut sprockets in substantial accordance with the form recommended, and trucks fitted with such sprockets had been run for many thousands of miles. Horine remarked that the largest manufacturer of chain-driven trucks had had no opportunity of discussing the merits of this form of sprocket, and he would like to have the report referred back. On the matter being put to a vote the recommendation was adopted.

Insulated Cable

The report of the Electrical Equipment Division was read by A. D. T. Libby, chairman. It covered general specifications of insulated cables, tests, specifications for high-tension (secondary) ignition cables, low-tension (primary) ignition cables, rubber-covered lighting and starting cables, varnished cambric insulation starting and lighting cables, armored starting and lighting cables and a revision of electrical equipment nomenclature. The 7-mm. size was recommended for all high-tension cable.

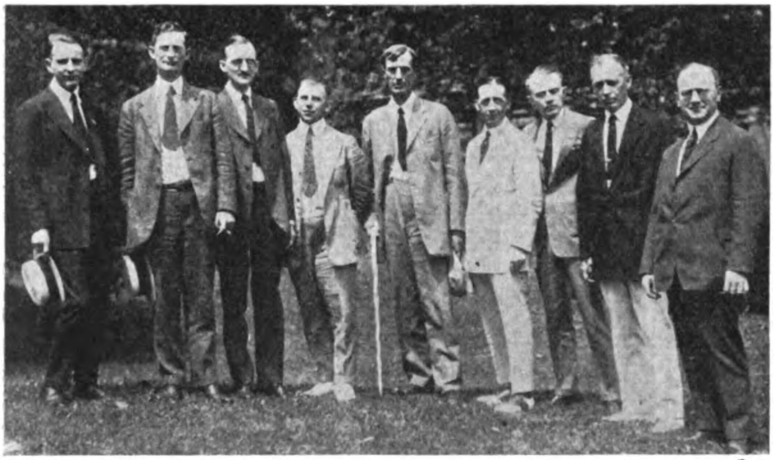
This was objected to in a communication from H. B. Burley of the Boston Insulated Wire & Cable Co., a member of the committee, who said that about one-half of the high-tension ignition cable supplied by his firm was of the 9-mm. type. The production of this cable was a matter of evolution. His firm had been called upon to supply cable for some unusually severe service, for which the 7-mm. cable was found inadequate. To this objection the reply was made that 7-mm. cable had been found satisfactory on motorcycles, which was about the severest service encountered in automotive practice. One objection to the use of more than one thickness of insulation is that all connectors and clips also have to be made in more than one size. The report was adopted as read.

That section of the report dealing with nomenclature also led to some discussion, especially as regards the proper name for that part of the ignition system which performs the functions of a circuit interrupter and a spark distributor. The report recommended timer-distributor, and this part also was adopted without change. Another recommendation of this division that was adopted was to cancel the present S. A. E. standard for magneto flexible disk couplings and insert the following note under the drawing of the standard magneto mounting: Magneto couplings shall be 2⅜ in. long and have a maximum diameter of 3¼ in.

Battery Rating Cancelled

L. S. Keilholtz presented the report of the Isolated Electric Lighting Plant Division, which related to a new proposed rating for farm lighting set storage batteries. It was recommended to cancel the present intermittent discharge rating and adopt instead a method of rating based on the number of hours' discharge capacity at a constant discharge rate of 300 watts. Mr. Keilholtz explained that he was personally much opposed to the recommendation of his division, and he moved that the report be referred back to the division for further consideration. After extensive discussion pro and con, it was voted to adopt that part of the report recommending the cancelling of the present standard rating and to refer the rest of the report back to the division. This leaves the S. A. E.—provided the action is approved by the membership's letter ballot—without a battery rating standard for isolated lighting plants.

The report of the Lighting Division was read by C. E.



Bearings Group, F. H. Lennox, H. C. Brunner, O. P. Wilson, D. P. Chambers, F. W. Gurney, Norman Bell, H. D. Rumlman, H. G. Freeland, F. M. Germane.

Godley, chairman. This covered headlamp brackets, motorcycle headlamp mounting, lamp nomenclature and bases, sockets and connectors; it was adopted.

Ball Studs Report

There was considerable opposition to the proposed recommended practice for ball studs, both from representatives of manufacturers of such studs and from representatives of car and truck manufacturers. It was claimed that on one particular size the neck dimension was too small to permit of the required angular motion of the ball in the drag link. No provision was made for running out the thread chasing tool, the type of nut which was intended to be used was not mentioned, and M. C. Horine stated that, since the ball had to engage with surfaces produced with standard reamers, the ball diameters should be slightly below the nominal sizes. A vote was taken, and it was decided to refer this part of the report of the Parts and Fittings Division back to the division.

Exhaust Pipes

Some discussion also arose over the proposal that the outside diameters of exhaust pipes extending from the engine to the muffler shall conform to the following inch sizes: 1, 1¼, 1½, 1¾, 2, 2¼, 2½, 2¾, 3, 3¼, 3½ and 4. Menges said that in stationary engine practice it was customary to use wrought iron pipe, and there was some possibility of the sizes given being mistaken for wrought iron pipe nominal sizes. The recommendation was adopted with the proviso that the wording be so amended that there can be no possibility of mistaking the scope of the recommendation.

Two other items were covered in the report of this division; namely, square shaft fittings and universal joint hubs, and both were adopted as offered. By the item on square shaft fittings the thread at the end of the shaft is changed to an S. A. E. standard thread, which brings the square fitting in line with the taper fittings.

The universal joint item specifies the hub dimension and the distance from the end of the bolt projecting from the flange to the outer face of the hub.

The report of the Engine Division, covering slight change in the thickness of cast iron carbureter flanges and extension of the disk clutch flywheel housing standard, was adopted as read.

The report of the Screw Thread Division, covering proposed recommended practice in the matter of drain cocks, was adopted as read, after some discussion, in which the use of the ⅛-in. size on radiators was criticized. It was made clear that this size was not specifically intended for use on radiators but could be used in other places; on the carbureter for example.

Social and Sport Features

THE social and sport features of the semi-annual meeting were never better handled, and despite the handicap of the weather conditions a good time was had by all who were willing to enjoy themselves.

The great atrium, or rotunda, in the center of the circular hotel building was an ideal playground for the evenings and for loitering and conversations during the showery days. Also, it supplied all of the elements of out-of-doors with a relief from the sun for those who did not care for southern Indiana spring temperatures.

In this atrium the evenings were especially gay. Without being in each other's way, there were the dancing party each evening, with just as much space as was desired; private card parties; informal receptions by those who had a large list of acquaintances among the members; family parties; playgrounds for the few children present, with plenty of floor space to spare, and had C. F. Kettering carried out his threat to come in his airplane, there would have been air space for him to have staged a stunt exposition. But there were no airplanes present—much to the regret of those who were looking forward to an aerial sport program as a part of the meeting. Kettering and his plane were both missing.

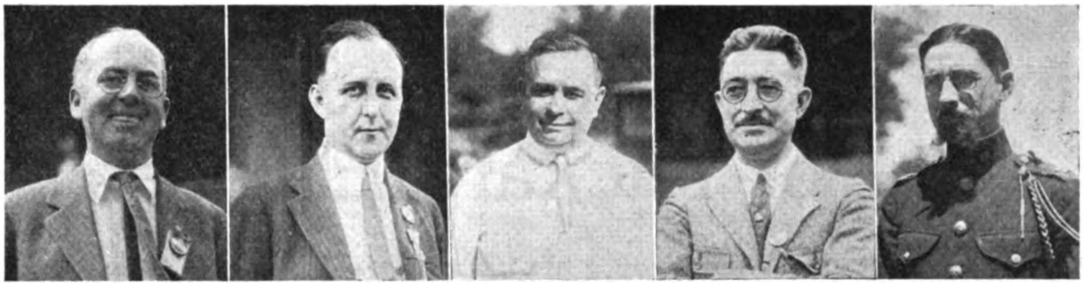
In addition to this very liberal allowance of space, there were a large office lobby of a more formal sort and great stretches of porch, an ample lawn and acres and acres of near-mountain land, on top of which was a very sporty golf course.

Indeed, it was one of the interesting features of the meeting to see golfers in their tweeds taking a taxi for a five-minute ride up the hill to the course where they would spend several hours walking on ground almost as rough as the hillside. The game completed and the score safely in the hands of the men in charge of the contests, the players again immediately forgot the benefits of physical exercise and called the taxi and rode comfortably to the hotel. While this was going on, scores of non-golfers were climbing this same hill for exercise. The golf events were especially well contested and were conducted continuously despite the showers.

The most notable feature of the sports—to judge by the scores—was the trap shooting. For each of the four days there was a score of 49 out of 50, and on more than one occasion it was necessary to shoot off ties at this score. J. A. Fesler made this score on two days and D. F. Fesler and W. H. Miller equaled his shooting.

The ladies' events on the sport programs attracted the largest crowds, and there was always something on the grounds when the weather permitted. There were many close contests, much good-natured rivalry and many new acquaintances formed here.

The tennis players had a difficult time of it. The courts



F. E. Watts nominee for second vice-president, representing motor car engineering.

Chas. S. Crawford V. G. Apple F. N. Nutt

Mark Smith, Disguised as "Capt. Merino, eminent representative of the Italian Goverment."

were the poorest part of the West Baden equipment, and the rain played havoc with the arrangements. The matches were started on Tuesday, but after two days' necessary recess a fresh start was taken Friday and a busy afternoon resulted. When dark came the matches were not completed and the winners in these events did not get to walk up before the Friday night crowd and claim their prizes. A proud moment in the lives of these champions was destroyed by the fickle Indiana rain god. So here are the results: Men's doubles—Final round, Bates and Buetner defeated Crane and Clarkson, 6—3, 0—6, 6—4. Men's singles—Final round, Clarkson defeated Buetner, 6—1, 6—1.

There were the usual stunt features, and it is no reflection on any previous program to praise them. The most pretentious was Indiana Night, staged after dinner on Wednesday evening. It was the plan that former Senator Albert Beveridge should be the speaker, but he was unable to be present. The committee was fortunate in being able to obtain former Senator Thomas Taggart, an Indiana political power, as a substitute. Taggart is the owner of the French Lick Springs Hotel, a rival to the West Baden Springs Hotel, and he gladly came from his entertainment palace to speak to the biggest convention the rival hotel has housed. His talk was on the practical side of the good roads question. It was at this meeting that a telegram from Gov. McRea of Indiana, extending the best wishes of the people of the State to the convention, was read.

After the speaking program, the annual Indiana stunt was presented. It had been quite a serious program and there was no surprise when an Italian army captain was introduced to speak on the automotive developments of the Italian engineers. He started well, explaining some highly technical lantern slides, when a considerable amount of disorder developed in one section of the dining room. When this racket continued, several of the more serious members of the society left, feeling that an eminent and worthy guest was being insulted. As they reached the hall they heard loud applause and laughter, and returned to find that the supposed scientist was really Mark Smith of Chicago. Several favors were distributed at this meeting.

On Thursday afternoon the Cleveland section staged a circus in the center of the atrium, and the quantity of peanut shells left on the floor was a strong feature of the occasion. The performers did their part well, and much amusement was experienced by those present. It is said to be a matter of record that this was the only session of the meeting at which the attendance was greater at the finish than at any other period of the meeting.

After dinner on Thursday the Metropolitan Section invited all present to come to the convention hall to hear Prof. Albert Einstein, the German scientist, explain his theory of relativity. The hall was well filled and the eccentric-looking visitor was well introduced by H. M. Crane in a talk which a portion of his audience understood and which betrayed not the slightest gleam of humor. Then came a heavy mathematical talk in an unusual German dialect which progressed nicely until by a premeditated accident it was revealed that the speaker was Cornelius T. Myers, who was quite well disguised and who had acted quite unlike himself.

The last night of the meeting was—according to precedent—designated as Ladies' Night and was quite a brilliant occasion. It brought out an unusual showing of evening gowns and the politest garments the men had brought along. The first feature of this occasion was the dancing contest, in which a dozen couples entered. The judges had quite a difficult task in the elimination, and be it said to the credit of the ladies that most of the eliminations were due to the hopping proclivities of the men.

After the dancing contest came the distribution of the prizes, and here the organization headed by Howard A. Coffin proved themselves. The usually troublesome task of distributing so many prizes went off smoothly, and was quite an interesting feature of the evening. A special vote of thanks was registered in loud tones for each person on the sport committee, with a cheer for Miss Mattle of the S. A. E. staff. The only sport disappointment was that the section baseball games and similar sports had to be abandoned.

As this was the last night of the session, the hotel management suspended the usual rule for midnight quiet, and music and dancing continued until almost breakfast time.

The Aeronautic Session

(*Continued from page* 1156)

propriation of $50,000 for a landing field for the Post Office airplanes but now they wanted their money back. He expected some good results from the reorganization of the Aero Club of America which up to now had been nothing more than a local organization, but now, under the leadership of Howard Coffin and of A. G. Batchelder, who had done good work in the A. A. A., it was to be made a national organization. It was planned to secure thousands of members and with nominal membership dues of, say, $5 or $10 each, there would be considerable funds available for propaganda purposes.

Routine Factory Tests and Final Inspection of Packard Engines

Operations include five hour running-in during which engine is driven by an electric motor, and two hour dynamometer test in silent room, where measurements of power developed, compression pressure of each cylinder. fuel consumption, etc., are made, and noises are located.

By J. Edward Schipper

THE final step in the routine manufacture of the Packard passenger car and truck engine is a very thorough test and inspection of each engine. After final assembly is completed, all engines are put through this same test, which is in very noteworthy detail and provides an accurate check on the condition of every engine before it leaves the factory.

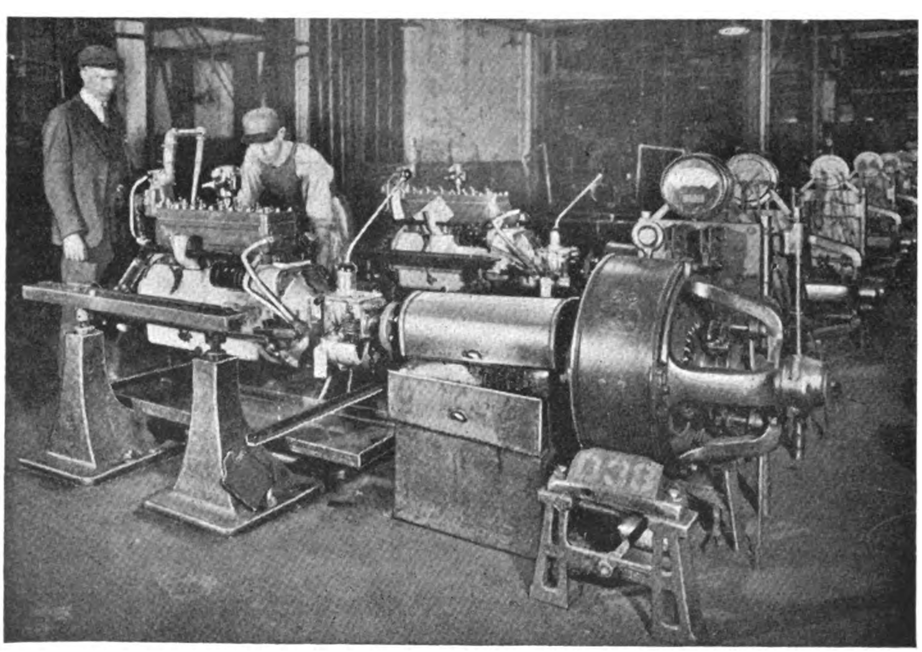
When the engines leave the final assembly department they are brought to a running-in room where they are run-in by electric motor. The transmissions are completely assembled with the engine so that the engines are run-in through their own gears. The first run is for 1 hr. in high gear. The electric motors which drive the engines are direct connected and run at a constant speed of 625 r.p.m. during this period. The amperage required is from 6 to 7 at the start of this run. Following the 1-hr. run at 625 r.p.m., the engine is given a 4-hr. run in second gear, during which the engine turns at 1000 r.p.m.

During the run the engine is gone over to locate leaks, scores and all the troubles which it would be possible to locate in an open room of this kind with several engines being run-in at the same time. When the engines are put on the running-in stand, a dynamometer inspection card is attached to the engine. This card stays with the engine during this running-in process and during the subsequent operations necessary to the completion of the inspection and tests. On this card are listed all of the probable troubles which can be detected during the running-in period as well as during the subsequent dynamometer inspection. Few notations can be expected on the card during the running-in process, which is purely a matter of working in the bearings and putting the engine in condition to run under its own power. The wattage required to run the engine or, in other words, its frictional resistance to being turned over by the electric motor is, of course, entered, as well as the number of the jacks or electric outfits employed in the running-in process. The engine is checked over for tightness of all of the nuts and bolts which can possibly become loose.

The motors used for running-in are Westinghouse direct-current type, 15 hp., 230 volts, 57 amp. The motors are operated on 220 volt, direct current, generated in the Packard plant. As soon as the 5-hr. running-in process is completed the engines are brought to a bench where the spark plugs are put in and the ignition is timed. This is set by a mark on the flywheel 1½ in. ahead of center with the spark lever in the full advanced position.

The engines are then lifted from the rack on which they were taken to the bench and rolled by means of an overhead track to the dynamometer rooms. There are 15 of these so-called "silent" rooms, each capable of handling an engine every 2 hr., or 5 per day, giving a capacity of 75 engines per day in the passenger-car department. The dynamometer equipment consists of Sprague 150-hp. dynamometers.

Including the mounting and dismounting of the engine on the dynamometer stand, there are 32 operations in the dynamometer room. These are as follows: 1. Connect engine to dynamometer stand. 2. Connect all controls and examine generator brush. 3. Check all nuts for tightness. 4. Check line-up of valves and push rods. 5. Measure and adjust carbureter spring. 6. Run engine with dynamometer. 7. Try oil level. 8. Try valves for riding. 9. Locate and stop compression leaks. 10. Start engine on own power. 11. Check generator for groan, and open circuit and see that ammeter reads

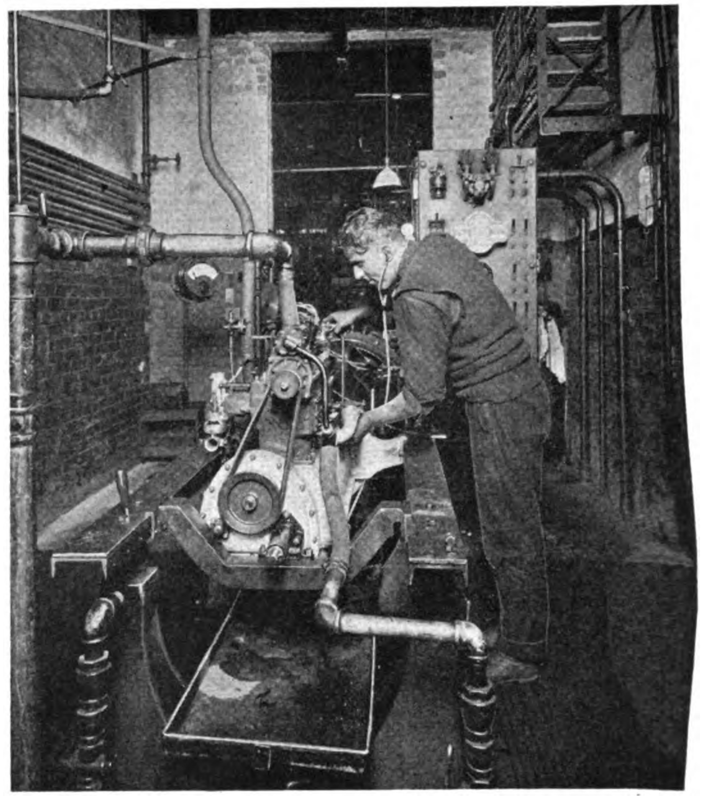


TESTING PACKARD ENGINE
Packard single-six engine on the running-in stand, where it is driven by direct connection with an electric motor.

correctly. 12. Try cylinder for knocks and scores. 13. Give engine hard run for 10 min. 14. Look over engine carefully, tighten all nuts, locate leaks, cracks and sand holes. 15. Throttle engine to observe low-speed performance. 16. Take power curve from 400 to 1800 r.p.m. 17. Check for gasoline mileage. (This is done on a special device which measures out 1/20 of a gal. The engine is set to pull 21 lb. on the dynamometer and the engine must run from 153 to 160 sec., which is equivalent to about 19.2 to 20.5 miles pei gal.) 18. Set the oil pressure. 19. Try cylinders for knocks and scores with stethoscope. This is the Locophone made by Baylis company. 20. Try the transmission at first, second and third speeds for lost motion in the shifter shaft. 21. Examine clutch for release, rough plate knocks and growls or slipping. 22. Try the tire pump. 23. Try the starter gears. 24. Try the front-end gears. 25. Try the cylinder base for oil leaks or gasoline leaks. 26. Look for exhaust and air leaks. 27. Throttle engine and try for low-speed miss, low to 100 r.p.m. 28. Check the carbureter. 29. Idle five min. for smoke. 30. Set the push rods. 31. Take compression on standard compression gage. This is the compress-o-meter made by the Brown company.

The engine, after this routine work has gone forward, is taken out of the rack the bottom taken off and washed out and the bottom screens, which have hitherto not been assembled in the engine, put in. After the bottoms have been washed out and the engine examined all over for loose nuts, loose cotter pins, flaws and defects of any kind, the bottoms are put on and the engine sent to stock.

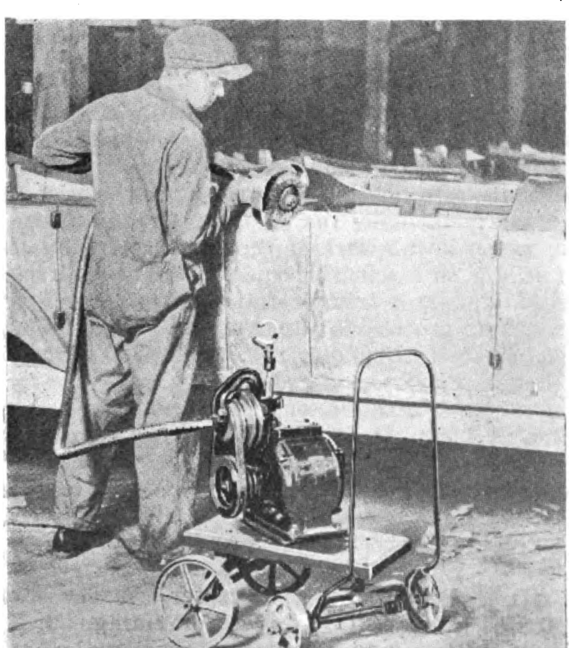
As a final inspection, the engine is sent out on the road test with a road-test card attached, as shown. The majority of troubles to be observed are, of course, not engine troubles, but this enters in. It is interesting to note that the final road test is an administrative department matter entirely and out of the hands of the factory. That is, the road testers are responsible to the president of the Packard Motor Car Co. and cannot in any way be held to factory or shop requirements. Thus, the final check-over of the car is independent of anything which may have been done as a plant operation.



Testing Packard Engine
Packard single-six engine on the dynamometer in one of the silent rooms where final inspection is given

Roughening Aluminum Body Panels

ALUMINUM sheet, as it comes from the mill, is exceedingly smooth and its surface does not hold paint well. It is therefore roughened by mechanical means before the first coat of paint is applied to the body.



Haskins equipment for roughening aluminum body sheets.

The attached cut shows a Haskins Type H-7 equipment in use in the automobile body building industry. These machines are used with a stiff wire scratch brush. The equipment consists of a 1 hp. motor, a three-speed counter shaft (giving spindle speeds of 900, 1800 and 3600 r.p.m.) and 6 ft. of Haskins flexible shafting.

Motor Car Fuel Economy Trial

THE Royal Automobile Club of England has announced its intention of holding a national fuel economy trial on Saturday, May 7 next. The object of the trial is to demonstrate the possibility of obtaining greater fuel economy in the use of a car than is at present generally the case, and it is pointed out that greater economy can be obtained by various methods, such as (a) a more economical adjustment of the carbureter, with very slight depreciation of the car's performance; (b) greater skill in driving, and (c) the fitting of auxiliary devices, such as extra air valves, the last-named method, of course, being obviously only of economic advantage when the saving achieved justifies the expense of the fitting. The trial will take the form of a fuel consumption test of not less than 40 miles and not more than 60 miles on a circular route, on the public road, and it will be open to all comers, whether members of an automobile club or not. Entries will be received from individuals only, who may each enter only one car.

Selling Trucks by Solving Transportation Problems

By specific examples and definite data, the author explains how one truck manufacturer has built up permanent customer good-will and increasing truck sales through analysis of the buyers' transportation needs. The analysis includes material handled, storehouses, and many other factors.

By N. J. Ocksreider*

THE motor truck industry has within the last two or three years entered upon a new period in its growth. The days of experiment and the days of development of manufacture are over to a large extent, although there are still many questions of detail and refinement which the producer has to solve. But we do know how to make remarkably efficient transportation machines at a reasonable cost.

This new era is the result of realization by truck men that a vehicle which is wrongly sold is a liability instead of an asset. In days gone by, too many truck salesmen sold anything they could to haul whatever was to be hauled. As a result much overloading developed trouble or underloading increased expense, and both combined to cause lack of satisfaction not only with the particular truck sold but with the truck as a transportation agent..

Manufacturers and dealers realize today that, so far as possible, they must place themselves in the position of transportation experts, competent to give sound advice on questions arising in this field. Salesmen must be employed who are capable of analyzing their prospects' requirements and these salesmen must be encouraged—they must if necessary be compelled to advise the prospect to act in his own interest even at the cost of losing the sale. It is a great credit to the industry that there are many cases on record where this attitude has been adopted and practiced.

It is obvious, of course, that the manufacturer makes trucks to sell, but it is precisely for this reason that he should see to it that his trucks are sold only where they can perform their work economically. This policy will inevitably develop repeat customers, widespread advertisement and great good will; any other policy will create enemies. The motor truck in its proper place is one of the greatest assets of modern life—misplaced it is an economic waste.

If a salesman is to be sure that his truck is properly sold be must be fully informed about the prospect's requirements and he must be capable of analyzing them honestly and intelligently. He must be able to observe analytically. He must find the truck problem as it exists and prescribe the proper answer. Often an analysis of the customer's problem shows the salesman that the vehicle he sells cannot be used. He must then so inform the buyer and advise him what equipment he should adopt if any is needed.

In the modern business world there are many problems of high class transportation which become too complicated for easy analysis. In literally thousands of cases the buyer himself does not understand his own needs and he does not even have at his command the facts which will make possible an intelligent analysis. It is cases such as this that have developed a new field in the automotive industry—that of the transportation engineer. His is the duty of studying these large and complicated problems and of finding the answer. His purpose must always be the interests of the customer, even if they seem to conflict at the moment with the interests of the selling organization. His object must be to tell the customer in what way he can handle his transportation most efficiently and economically.

It is obvious that in this problem there is involved far more than the qualities of the truck itself. Road and shipping conditions, kinds of freight, methods of packing, seasonal variations in business handled, all such matters as these must be taken into consideration. In the analyses that have been made by the transportation engineers employed by the Packard, recommendations have been brought in involving such varied matters as a new form of package, changes in the arrangement of shipping room and loading platforms, changes in the hours of work, systems for routing and dispatching traffic, and as minor a matter as bagging coal at the yards instead of at the point of delivery. All these things are at first glance outside the range of a truck salesman; actually they have all helped in the sale of trucks and have helped still more in the satisfaction which the buyer has found in the use of his equipment. The reason is that they have all helped him solve his problem and save or make money.

This work falls naturally into two divisions. The first one, which is the field of the transportation engineer, is in studying and solving the transportation problems. The second, which is the work of the truck salesman, consists in the selling on a scientific analysis whether it has been furnished him by a transportation engineer, or whether the immediate problem is so simple that he can analyze it himself. In this article only the problems of the transportation engineer are considered.

When a transportation engineer undertakes the solution of a problem his first need is facts. In instructions issued by the Packard to its engineers there are listed forty-two questions which must be answered before solution can even be attempted. The engineer starts out equipped with note book, camera and usually a large scale map of the territory in which the hauling problem is located. He begins by getting in contact with all the officials connected with the hauling problem and secures a plan of the works, to be used in handling questions of internal routing.

*Chief transportation engineer, Packard Motor Car Co.

He begins his analysis with a study of the material handled, both raw and finished, finds out what it is, how it is received and shipped, in what kind of packages and by what transportation means, whether water, rail, motor truck or team. He studies the question of storehouses and secures data on the amount and kind of material moving in and out of each shipping or receiving point.

Studying Costs

He then takes up the company's present hauling equipment, the number of trucks or horses owned or hired, particularly with reference to peak seasons. He makes a careful study of the cost of this haulage, finding out what the expense is for hiring either trucks or horses, gets the freight rates and the express and motor haulage rates and the frequency and adequacy of the existing freight express, boat or motor haulage services.

He then makes a careful study of operating costs of company owned equipment, both horses and trucks. This cost he divides into fixed and variable charges and if possible reaches ton mile costs on both types of equipment. He studies periods of idleness and the possibility of avoiding them. He takes up the quantity and cost of repair service on the company owned equipment and garage facilities. He learns whether gasoline or oil are properly bought, checked up and handled. He investigates any special equipment that has been used and determines what success it has had.

The next point taken up is the routing and scheduling of the hauling. This is done in detail, finding for what purpose each unit owned is used, and why. He follows this with a study of the road conditions for the year around, including all bridges that must be used. He finds the average and the best possible running time between all points and investigates whether there are any city ordinances which need to be taken into special consideration.

Platform Survey

A survey is also made of all shipping and receiving platforms. In doing this the engineer surveys back of each loading and receiving platform to the shipping or receiving room, watches the boxing, crating, sorting, assembling and internal routing so as to get an idea of the relationship and importance of each platform. He particularly checks up waste of time where products are taken twice over the same ground and where different goods are loaded at different times on the same truck. Where material is being shipped by freight or boat he determines whether it could be handled more economically by truck by learning from the company's records what a saving could be effected on boxing and crating.

Finally he learns the sentiment of the company toward its existing service and equipment, the reasons for desiring new equipment and the attitude of the various men involved toward the equipment that the company offers for sale.

With this material in hand the engineer is ready to start on the actual analysis. The method for this will naturally vary considerably, but in general his task is to establish two things. First, present cost of handling the necessary tonnage. Second, the best possible method for handling the necessary hauling and its cost.

To show how a typical problem of this type is worked out there follows a report made to a corporation at a town in Massachusetts which we will call Blankville, on shipments between its plant and New York City and Newark:

Blankville Analysis

The cost per week to ship merchandise from Blankville to New York City, Newark, and return, by the methods and the combination of methods that have been considered, are presented below:

FROM BLANKVILLE, MASS.:

Using the Standard Motor Express Rate, Plus 3 Per Cent for War Tax

To New York City—$1.00 per cwt. multiplied by 10.5 tons (210 cwt.) of finished product	$216.30
To New York City—$1.00 per cwt. multiplied by 1.7 tons (34 cwt.) of empty drum return	35.02
To Newark—$1.35 per cwt. multiplied by 2.5 tons (50 cwt.) of finished product	69.525
Total cost per week to ship all tonnage by standard motor express	$320.845

Using the Total Freight Rate Plus Cartage Plus 3 Per Cent of Total for War Tax

To New York City—First class L.C.L., $1.11 per cwt. multiplied by 10.5 tons of finished product	$240.09
To New York City—Fourth class L.C.L., $0.72 per cwt. multiplied by 1.7 tons of empty drum returns	25.21
To Newark—First Class L.C.L., $1.36* per cwt. multiplied by 2.5 tons of finished product	70.04
Total cost per week to ship all tonnage by freight	$335.34

*NOTE.—Cartage at Newark end estimated at New York City rates.

TO BLANKVILLE:

Using the Standard Motor Express Rate, Plus 3 Per Cent for War Tax

From New York City—$1.00 per cwt. multiplied by 9.74 tons* (195 cwt.) of raw material	$200.85
Total cost per week to ship all tonnage by standard motor express	$200.85

*NOTE.—Assuming that all phosphate is shipped from Long Island City.

Using the Total Freight Rate Plus Cartage Plus 3 Per Cent of Total for War Tax

From New York City—First class L.C.L., $1.11 per cwt. multiplied by 2.4 tons (48 cwt.) of triphenyl, acetone and miscellaneous	54.878
From New York City—Second class L.C.L., $1.00 per cwt. multiplied by 1.14 tons (22 cwt.) of castor oil and mirrors	22.66
From New York—Third class C/L*, $0.71 per cwt.† multiplied by 6.2 tons (124 cwt.) of phosphate	90.68
Total cost per week to ship all tonnage by freight	$168.218

*NOTE.—It is assumed that phosphate shipments are received in full carload lots, minimum weight 30,000 lb.
†NOTE.—It is assumed that this merchandise is loaded direct into freight cars at the plant from which it is purchased, eliminating a local charge for cartage.

It is obvious that it would not be profitable to ship all merchandise either by Standard Motor Haulage or Freight in either direction. Therefore, selecting from the above a combination of methods most suitable for your requirements, under normal flow of traffic, we have the following combination for consideration:

Merchandise Shipped by Standard Motor Haulage

Finished product from Blankville to New York City and Newark (260 cwt.)	$285.825
Raw material, castor oil, mirrors, triphenyl, acetone and miscellaneous to Blankville (70 cwt.)	72.10
Total cost per week for standard motor haulage	$357.925

Merchandise Shipped by Freight

Phosphate from New York City to Blankville (124 cwt.)	$90.68
*Empty drum return from Blankville to New York City (34 cwt.)	25.21
Total cost per week for freight	$115.89
Combined total cost per week	$473.815

*NOTE.—For the last six months these drums have been returned by standard motor haulage due to an embargo at New York City end.

We suggest the following method to improve the combination method, outlined above, in order that it will be possible to:

1. Place the shipment of both finished product and raw material between Blankville and New York City and Newark on a set schedule.
2. Place the New York office in a position so that their customers may be accommodated to a greater extent than at present.
3. Reduce the present transportation cost.

By installing a Packard size "EF" truck we believe it would be possible to put into operation the following method that would permit you to:

1. Haul the average weekly tonnage of 24.44 tons in two round trips per week at an average load efficiency of 81 per cent.

Equipping a Packard size "EF" truck with a 13 mile axle, it is believed possible to make a round trip between Blankville, Mass., and New York City in three days, each day sub-divided as follows:

Proposed Operating Schedule

Day	Max. Speed M.P.H.	Est. Aver. Speed M.P.H.	Max. Speed Min. Hours on Road	Est. Speed Aver. Hours on Road A.M.	P.M.	Distance	Leave	Time	Arrive	Time
1	13	9	10.1	7.3	7.3	132	Blankville	5:00 A.M.	New Rochelle	8:30 P.M.
2	13	9	1.3	2.0	..	18	New Rochelle	7:00 A.M.	N. Y. Office	9:00 A.M.
2	13	9	5.7	..	8.3	75	N. Y. Office	11:00 A.M.	New Haven	8:18 P.M.
3	13	9	5.6	5.5	2.6	73	New Haven	5:30 A.M.	Blankville	3:36 P.M.

*NOTE.—It is estimated that no hours will be required in New York to exchange loads and that during this interval the truck will cover 5 miles.

Summary

The present cost to ship merchandise by the selected "combination of methods" to New York City, Newark and return is as follows:

Cost per week	$473.815
Cost per day	78.969
Cost per trip	236.907
Cost per cwt.	.97

The operating cost of a size "EF" truck to do this same work is estimated to be:

Cost per week	$331.80
Cost per day	55.90
Cost per trip	165.90
Cost per cwt.	.68

This is delivered to New York City only. To this cost there should be added an additional charge for shipping 2.5 tons of finished product from New York City to Newark at a local charge of 50 cents per cwt., plus 3 per cent of total for war tax or $25 per week, making a total cost of:

Cost per week	$356.80
Cost per day	59.46
Cost per trip	178.40
Cost per cwt.	.73

Comparing the final cost of operating company owned equipment with final cost of shipping by the selected combination method the following saving is believed possible through the adoption of company owned Packard trucks.

	Saving
Per week	$117.02
Per day	23.07
Per trip	58.51
Per cwt.	.24

In a year of 288 operating days it is estimated that this would be an approximate saving of $6,644.16.

To this is attached a detailed estimate of the cost of operating the trucks, which has been summarized in the previous report. As an example of the method of making use of these estimates, there follows one submitted in a report to the New York *Globe*, when it was considering hauling its papers from the St. Lawrence River to Burlington, Vt., during the period of serious freight congestion some months ago. This gives both the basis for an individual truck, and operating nine trucks a week.

OPERATING 9 UNITS FOR A WEEK—18 ROUND TRIPS—250 TONS

OPERATING COST PER WEEK

Figured on 250 Tons

Miles	5040	miles total
Garage 9 units @ $6 per week	50.00	
Driver—8 crews for 3 fleets.	1152.00	24 men @ $8 day for 6 days
Taxes estimated	20.00	for licenses for 9 units per week
Insurance $1.66 per day per unit	89.82	for 9 units for 1 week
Sinking fund	655.20	560 miles per unit per week
Interest	53.10	
Gasoline*	756.00	for 9 units for 1 week
Lubrication**	51.39	for 9 units for 1 week
Tires $.087 per mile	438.48	for 9 units for 1 week
Maintenance and overhaul	252.00	
Total cost per day	3521.99	
Total cost per year		
Total cost per mile		

Cost of $14.10 per ton

LUBRICATION PER 1000 MILES (Includes refilling)

	Necessary Gallons	Necessary Cost	Desirable Gallons	Desirable Cost
Cylinder oil				
Heavy oil				
Grease				
Cost per mile				.0102 per unit per mile

MAINTENANCE AND OVERHAUL
Repairs per unit—6 seasons—60,000 miles—total of $3,000.00.
Maintenance and overhaul for life of truck equals $.05 per mile.

TIRES
$877.30 ÷ 10,000 miles = .087 per mile.

MISCELLANEOUS
State license ....

GASOLINE

Miles per Gallon
Good Average Fair
2.0 at 30c. per gallon

*"Average" miles per gallon used in computation.
**"Necessary" lubrication used in computation.

Each problem naturally affords different factors and calls for a different method of solution. One of the problems recently was conditioned upon the hauling that had to be done across a bridge limited to 6 tons carrying capacity. Another was dependent upon the fact that the heavy haulage had to be done over an 8 per cent grade. In a third, that of handling ore from a Colorado mine; the answer was found by putting three trailers to each truck, so that on the haul from the mine the first function of the truck was to act as a break, while it had nearly a capacity load in returning the empty trailers to the pit mouth. Examples like this could be multiplied indefinitely.

It has been working out problems like this that convinced us of the necessity of rating the units sold to the particular job, and abandoning the old flat tonnage rating. It was clear that a truck that might carry 2 tons over an 8 per cent grade could handle 4 tons on a level.

For this reason we no longer sell the truck as of a given capacity, but after studying the hauling problems and determining how much freight should be carried we recommend the units that can do the work most efficiently.

Steel Castings and the Automotive Industry

The use of steel castings in the automotive industry is largely limited to trucks and tractors. The story of the growth of this industry tells the extent to which it has been influenced by automotive development.

THE use of steel castings has been quite extensive in certain phases of automotive construction, despite the fact that the automobile industry has not influenced the steel castings business so strongly as it has some others. Especially in the truck field has the steel casting been widely used, so that the steel foundries of the country can properly be classed as important units in the group which supplies the automotive industry.

Taken as a definite industrial unit, the steel castings industry is comparatively young. It is only during the last twenty or twenty-five years that the production of steel castings has been carried on in any large way. It is said that the first steel castings of which anything is generally known were made by the William Butcher Steel Works in July, 1867. Not until about 1896 or 1900, however, did the steel castings business assume any considerable proportions.

During the very early stages of the steel castings industry, says David McClain in *Foundry*, "great secrecy and caution were exercised in handling mixtures by those whose duty it was to oversee this part of the business, and symbols instead of names were used to specify alloys for steel mixtures."

In 1884 the first Bessemer converter devoted entirely to the manufacture of steel castings was put into operation by the Pittsburgh Steel Castings Co. The early furnaces used in steel casting manufacture, however, were short lived and unsatisfactory in many ways. The acid open-hearth furnace marked a step in advance, however, and about 1896, twenty-five years after the beginning of steel casting manufacture, the installation of a 20-ton acid open-hearth furnace determined the superiority of the open-hearth furnace over the crucible or converter.

The electric furnace is a development of recent years and marks another notable point in the growth of steel casting practice. All three methods are still in use, although the chief obstacle to the more widespread usage of the electric type seems to be that of cost.

There has been a rapid growth in the number of steel foundries during recent years. One authority attributes this to the fact that more men have been taught the technical details of steel casting manufacture, so that many employees have gone out and set up small establishments of their own. He believes that the growth was less rapid during the first decade of this century because there were so few men who really understood how to make steel castings successfully.

At the present time something like 1,000,000 tons of steel castings are produced each year in this country. A large proportion of this output is usually absorbed by the railroads, while the machine builders are also large consumers. While there has been an intimate connection between the steel castings and automobile industries during recent years, it cannot be said that the steel casting manufacturers are strongly dependent upon the automotive industry or that the automotive industry has had a very large part in causing their technical and commercial development.

There are some 250 foundries in the United States which make steel castings. About 190 are independent foundries producing castings for the trade, while about 135 are devoted exclusively to the manufacture of steel castings.

Assuming that the output of steel castings is about 1,000,000 tons a year, the distribution of this output is probably something like this:

Railroads	60%	600,000 tons
Machine Builders	25%	250,000 tons
Automotive Industry	8%	80,000 tons
Miscellaneous	7%	70,000 tons

These figures are merely approximate and are based upon the opinions of several men long connected with the industry in its broadest phases. Definite statistics are not available as regards the steel castings industry. The Steel Founders' Association, which includes the firms producing a large proportion of the total tonnage of the industry, states that it has no information available along these lines and that it is not interested in supplying material or in discussing articles designed to give to outsiders some view of the technical and commercial growth of the steel castings business. Individual members of the Society, however, have been extremely helpful in supplying information and suggestions.

The Society has about 87 members at the present time and, as stated before, these firms produce a very large percentage of the entire output of the industry. Apparently no concerted effort has been made, however, along the lines of co-operative research or tests.

Qualities

The steel casting has characteristics which make it specially adapted to certain automotive uses. Steel castings are made in three grades, generally known as hard, medium and soft. The Society of Automotive Engineers has adopted the standard specification of the American Society for Testing Materials for steel castings. The physical properties required by these specifications are as follows:

	Hard	Medium	Soft
Tensile strength, lbs. per sq. in.	80,000	70,000	60,000
Yield point, lbs. per sq. in.	36,000	31,000	27,000
Elongation in 2 in., per cent	15	18	22
Reduction in area, per cent	20	25	30

The relatively high tensile strength of the steel casting renders it specially adaptable for use on trucks. The following list comprises some of the chief qualities of the steel casting:

1. Relatively high tensile strength as compared with other castings.

2. Machining off even a considerable thickness of metal does not appreciably affect strength of casting.
3. Intricate shapes can be cast which are not at present possible by means of drop forging.

In the early days of steel casting there was a great deal of difficulty experienced in getting the proper metal mixtures to produce the best castings. Progress along this line, however, has gone so far that little trouble is now found. One prominent steel castings man said recently, "Plain carbon steel casting of to-day has been brought to a point where the problems of manufacture are purely mechanical problems. . . . It is, therefore, time to work for better physical properties than those found in low carbon castings straight annealed."

Progress has also been made in heat-treatment methods which has enabled steel casting manufacturers to raise the average tensile strength of their product well above the limits that were previously possible. There is this difference between the malleable and steel casting which is of importance in the consideration of heat treatment and annealing. The steel casting does not rely on the annealing process for the development of any new qualities or properties; the heat treatment merely adds to those properties already present in the inherent nature of the material from which the casting is made. In the malleable casting, on the other hand, the heat treatment serves a purifying purpose and imparts to the casting qualities which it did not previously possess.

It is true, however, that the heat treatment of plain carbon steel castings yields an improvement of 20 to 50 per cent in strength. One manufacturer who has had considerable contact with the automotive industry said recently that "to meet the varied requirements of the truck, tractor and machinery castings we have developed a series of steels with yields points from 30,000 lbs. up to 110,000 lbs., and have obtained higher strength without undue sacrifice of machining qualities."

There are five factors which, in a general way, affect the final quality of the steel casting. These are:

1. Steel making practice,
2. Composition,
3. Moulding practice,
4. Annealing practice,
5. Design of casting.

The automotive engineer is concerned only indirectly with the first four of these factors. It is likely to be to his advantage to understand something of the practice involved in each of them, but he cannot be expected to be thoroughly conversant with all the phases in detail. He is the vital agent, however, in making the casting design. It is because of this fact that he should either understand steel foundry practice rather well or should take advantage of the opportunity for consultation with the castings manufacturer.

This matter of co-operation has been discussed in connection with drop-forgings, die-castings and malleable castings, but bears repeating because of its importance. How important such consultation is from the standpoint of the castings maker and how far back into the process of castings manufacture the design goes is shown by this statement, made a year or so ago by a big castings producer. He said:

"The desire is to persuade the designer of castings that exchange of views is important not only in respect to the production of castings, but also in regard to the use of differing qualities of steel for various purposes."

Two of the chief difficulties, for instance, in steel castings manufacture are unequal cooling of sections of the casting and the presence of blow-holes. As regards the first of these troubles, the design is very largely responsible. Where the sections are of very unequal thickness, unequal cooling is almost sure to take place, while some sections may be too thin to be poured successfully in steel at all.

The unequal cooling can be offset to some extent by "chilling" the thick parts, but there is a definite limit to the possibilities of this method.

Blow-holes come chiefly from improperly melted metal and from wet molds. These troubles have been eliminated in most high-grade foundries at the present time by properly melting the steel and adding to it suitable percentages of silicon and manganese.

There is some indication that the steel founders recognize increased possibilities for development through contact with the automotive industry, and that efforts to increase the importance of that contact will be made at least by individual firms. Discussing the effect of the war on the steel castings business, one executive said recently that it had had two effects:

1. It improved the general quality of steel castings because the Government made large demands, but had very rigid specifications.
2. This large demand developed a very greatly increased capacity for steel castings production.

He went on to state that much of this capacity was now excess and that the big problem before the producers was to develop new fields for the use of steel castings and new markets for the utilization of this excess capacity. He pointed out the fact that even some pre-war uses do not exist now because "the inability of truck and tractor manufacturers to obtain steel castings forced them to eliminate castings and substitute stampings or replace steel with malleable of heavier section."

As regards the function of the steel casting and the drop-forging, one casting maker says, "On quantity orders of simple design it is impossible for casting to compete with forging. But in the development of new models, where production is limited and die expense must be amortized over a few hundred pieces, steel casting is the logical material to use. It is also adapted to intricate shapes which cannot be forged."

Information as Selling Basis

To successfully sell a truck or tractor means even more than putting the vehicle in the hands of the user and collecting his money for it. The development of a permanent market requires that the proper vehicle be sold to meet the special needs of the particular user, and that proper service be rendered after the sale.

The Bates Machine & Tractor Co. has adopted a plan of going direct to the farmer for information as regards the possible usefulness of a tractor to him. A letter and questionnaire is sent to the prospect. The letter states that it is the earnest desire of the company to sell their tractor only to those who can really show a profit through its use, and explains that the purpose of the questionnaire is to get information for use along this line.

The questionnaire includes such questions as these: Total number of acres, acreage under cultivation, pasture, kind and nature of soil, estimated percentage of steepest grades, number of men employed, number of horses and mules, do you use tractor now, what make, do you own an automobile or motor truck, do you operate a thresher or an ensilage cutter, do you operate a centrifugal pump, what other belt work have you, what tractors have you had experience with. who is your best local dealer

A Foreman's Thoughts of Piece-Rate Cutting

It is a common human failing to attempt to dispose of complex questions by means of a ready formula. It has been said that under a piece-rate system a man is paid in accordance with his ability to produce. This is true, and yet the statement must be qualified. This foreman discusses the matter of cutting piece rates in his own practical, "two-fisted" manner.

By Norman G. Shidle

THE question of a fundamental basis for wage payments is one of the important problems confronting industry. The piece-work system is common to automobile plants, but varies greatly as to the methods by which it is administered. The cutting of piece rates probably causes as much trouble as any other single factor of wage adjustment.

The opinions of employers vary on the subject, while that of workmen is unanimously opposed to the policy. The views of an experienced foreman on the subject should be of interest to executives, since the foreman occupies an intermediate position between employer and employee.

The foreman in question is in charge of a department of nearly 100 men in an automobile factory. The men under his supervision are all piece-workers. The opinions quoted were not expressed in a formal interview of any kind, but merely in the course of a conversation about production methods. His conversation ran something like this:

"Yes, we are getting all the kinks in production pretty well ironed out now in this department. We recently installed a lot of new equipment, and the men are just now beginning to get the maximum value from it. Then they put the whole department on piece-work a few months ago.

"Piece-work has boosted production a lot. I am getting twice the production out of here now with two-thirds as many men as I had before. That is partly due to piece-work and partly to the new equipment.

"But, say, maybe I couldn't get out a lot more production from this gang if they would take off that 75 cents an hour limit on the piece-workers. We get about 400 a day out of here at present, and if they didn't limit the piece-work earnings to 75 cents an hour, I'm sure I could jump production to 600 without turning a hair.

"I've got a good bunch working in here, but when there is a limit like that put on they simply won't turn out any more. Sure, there's a limit. No, we don't tell the men that, but you can't keep that sort of thing quiet very long. It soon gets around the shop. One of the boys was asking me yesterday if it was true that there was a 75-cent limit. I just evaded his question somehow, but he knew just the same.

"And you can't blame them for not going over the limit when they know the rate is going to be cut. I'd do the same thing and so would you; be crazy if they didn't It's wonderful how close they can hit that mark, too. I had a department in a plant up in Detroit a year or so ago. When I went in there production was down low, and all the men were making between $7.90 and $7.99 as regular as the sun rose and set. Later the rate was cut. Every man in the bunch kept on turning in between $7.90 and $7.99 a day just the same. Again I say I don't blame them. I'd do just the same way.

"You can't expect to get maximum production from a man when he knows he is going to be penalized for doing his best.

"Huh? What is the sense of having a piece rate if it has a definite limit? Why not just pay the good men that limit rate and grade the others down accordingly? Hm. Well, now I don't know just what answer you could give to that. It does seem as though a piece-rate system with a limit like that was pretty nearly the same as a day rate basis with a minimum production requirement, doesn't it?

"Well, I don't know about the theory of the thing, but I do know that the boys will hold down production as long as they know the rate is going to be cut when they boost it to a certain figure. If they'd take that 75-cent limit off in this department, I'd soon show 'em some real production. Got a good bunch in here now, and they know that jobs are scarce outside, too."

This is not the opinion of a theorist, but of a practical working foreman of considerable experience in automobile work. Harry Tipper said recently that "of all the systems for general wage payments which are being used at the present time the ones which are predicated upon the relation between the individual and the quantity and quality of his production are the most effective in their general application."

All of which merely emphasizes the necessity of administering as carefully and as fairly as possible this inadequate method which is the best available for immediate use.

A NEW company has been organized in London with the object of reclaiming stale lubricating oil. The waste oil can be bought at prices ranging up to about $100 per ton and in some cases can be had for the cost of collection. It is planned to establish immediately a plant near London with a capacity for treating 50 tons per week, which, it is believed, can be easily collected in London, and other plants in the various large cities of the kingdom. Tests of the waste oil and clean oil made by a consulting analyst are said to have shown the following changes to have been effected by the process: Appearance changed from dark brown cloudy to dark brown clear; the gravity at 60 deg. Fahr. from 0.9180 to 0.9185; the acidity from 0.61 to 0.06, and the water content from about 1 per cent to a trace.

Medical Attendance in Relation to Compensation

Labor interests have seriously opposed the present method of making it the duty of the employer to provide medical attendance in compensation cases. They believe the employee should choose his own physician. T. W. Konop of the Wisconsin Industrial Commission discusses this point here.

ALTHOUGH the movement started too late to publicly gather national force in connection with the 1921 sessions of State legislatures, the proposition of what part the employer and insurer and what part the employee should have in the choice of medical and surgical attendance in the event of injury in industry is already a real national one, and is bound to intermingle with the other big items that are up for consideration in connection with industrial relations.

This question of medical attendance in connection with workmen's compensation is more vital than the item of money indemnity for injury, considered in a broad way. Labor interests are very serious in their opposition to the universal present method of making it the duty of the employer or insurer to provide such attendance. They will make the issue as big as they can.

Interests other than those of either employer, insurer or worker are not in favor of any radical change from the present method, chiefly because they have found that self-interest alone, on the part of employer and insurer, has given the worker entirely satisfactory attendance.

These were the leading thoughts expressed on the subject of compensation for injury in industry at the fourth Wisconsin Industrial Service Conference and Wisconsin Industrial Physicians and Surgeons, held at Appleton, May 17. Wisconsin, the leading State in the introduction of compensation insurance and State control of safety in industry, now has two bills before it on the subject of choice of attendance which are the models for other states, and this formed one of the main subjects at the conference. Thomas F. Konop, former congressman from Wisconsin and a member of the Wisconsin Industrial Commission, sounded the keynote of the discussion.

"Compensation to injured workmen, under our law, comprises two things, medical and surgical attendance and weekly money indemnity of 65 per cent of the average weekly earnings," said Commissioner Konop. "These two benefits are so linked together that they are dependent on each other. The amount of the second depends largely upon the character of the first. The better and more skillful the medical treatment, the lesser the period of compensation disability. Unskillful and negligent medical and surgical treatment lengthens the period of compensation disability, makes compensation costly to the industry and many times unnecessarily makes a cripple of the employee.

"To my mind, skillful and adequate medical and surgical treatment is more important to the injured person and to the employer as well than the money indemnity provided under the law. Skillful and adequate medical and surgical treatment is absolutely essential to the restoration of an injured employee's earning capacity, and yet in nearly all of the compensation laws of the country there are limitations on this service of from two weeks to ninety days or at a cost of from $25 to $300, sometimes both.

"Under the above provision the commission has repeatedly ruled that with this duty imposed upon the employer is a corresponding right to select the physician and surgeon who shall treat the injured workmen. The employer, therefore, is given the right to select, and has been exercising that right and insisting upon its exercise in Wisconsin."

The commissioner then spoke at some length on the movement on foot to change the system and give the right of selection to the employee, although declaring that personally, and he believed the other commissioners agreed with him, he was opposed to any radical change, that he believed the present system was working satisfactorily and that the kind of medical and surgical service that is being furnished to injured workmen is of the best.

Some of the reasons given why the employer should select the physician and surgeon were: He is in a better position to select a competent, skillful physician or surgeon; he is financially interested in the speedy recovery of the injured workmen and will, therefore, furnish the best skill possible; he has to pay the expenses and, therefore, should be permitted to make the best bargain and reduce the cost of this service; where the physician is selected by the employee the treatment is prolonged, bills are padded.

On the other hand, he said, the demand for a change has been growing all over the country. Two years ago a bill to amend the law and give the injured workmen the choice of medical attendant was withdrawn after a conference, when the employers agreed to take the matter up with the insurance carriers and bring about a condition that would give the injured employee the choice of another physician or surgeon if dissatisfied with the one offered, but practically nothing has been done to carry out this agreement.

There are two bills now pending before legislative committees relating to this feature; the Schafer bill would give the injured employee the right to select his own physician or surgeon and the Huber bill gives him the right to make a selection from a list provided by the employer.

Taking up the other side of the argument, Mr. Konop said it is argued the relation between physician and patient is confidential and personal and that sometimes the company physician discloses these confidences; that the best results are obtained

when the patient has confidence in the surgeon; that the physician selected by the employer restricts the period of disability, requiring the injured employee to return to work too soon in order to lessen the indemnity payments; that the physician is too devoted to the interests of the employer; while medical men have complained of the concentration of medical and surgical work into the hands of a few.

The commissioner discussed the various arguments at some length and with absolute frankness. He cited various cases which have come to the attention of the commission to prove this or that argument. He declared the absolute choice of a physician and surgeon by the employee was liable to be detrimental rather than beneficial to the injured workmen, and that one of the first results would be that the Industrial Commission would have to fix the schedule of fees for the medical profession. He said the most skillful physicians and surgeons would object to that to such extent that they would refuse to handle such cases and the workmen would suffer in the long run.

The Future of Airplane Manufacturing

IN a statement just released C. M. Keys, president of the Curtiss Aeroplane & Motor Corporation, asserts that "it costs at least $1,900,000 to develop any airplane motor to the point of successful production." He goes on to point out that the Government idea that airplanes and even aeronautical motors should be bought only under competitive bids is not conducive to scientific progress under these circumstances. The statement continues:

"It is fairly obvious that no company can spend that amount of money and suffer the grief and disappointment of experimental labor—which is so often lost labor—only to have the product of that labor, if successful, taken up by the Government and thrown open to competitive bidding.

"It is fair to say that because of these conditions, over which the industry has no control, not only the Curtiss company, but all other forward-looking institutions in this art, have curtailed their efforts, economized their resources and foregone their ambitions for the art in order to adapt themselves to the policies of their Government."

At the end of the war the Curtiss company was operating seven plants, employing 170,000 workers. It produced 5811 complete airplanes during the war, together with over 5000 motors. The following list indicates not only the location of the various Curtiss plants, but also the various lines of development along which research and progress is being made:

Research, Experimental and Production, planes and motors
- Garden City, N. Y.
- Churchill St., Buffalo, N. Y.

Rehabilitation and Overhaul,
- Waukegan, Ill.
- Atlantic City, N. J.
- Houston, Texas.

Repair and Supply Depots
- Garden City, N. Y.
- Waukegan, Ill.
- Atlantic City, N. J.
- Houston and Dallas, Texas.
- Riverside, Cal.

Flying Schools and Fields
- Curtiss Field, Garden City,
- Curtiss Field, Buffalo,
- Curtiss Flying Station, Atlantic City.

Airport, Newport News, Va.
- Waukegan, Ill.
- Houston and Dallas, Tex.
- Riverside, Calif.

Distributors and Agencies
- Throughout the United States, Central and South America and the Philippines, thereby vastly extending the service opportunities for users of Curtiss products.

The Garden City plant covers 260 acres. In addition to the shops, this factory contains a drafting department, an aerodynamical laboratory, a 7½-foot wind tunnel, a motor laboratory, chemical and physical laboratories, etc. The Buffalo and Garden City plants take the results of the scientific research made in the other plants and translate them into actual motors and airplanes.

The Curtiss company, according to Mr. Keys, believes in the future of commercial aviation and thinks that "the Government should provide sympathetic regulation, establish airports and lay out routes, etc.," while "the industry must do its part in providing the flyers with economical equipment and good service."

Sulphide Alcohol as Motor Fuel

A GREAT deal of alcohol made from the sulphide liquor of paper manufacture has been used as motor fuel in Sweden during the past several years, and a questionnaire regarding experiences with this fuel was circulated about a year ago by Prof. C. E. L. Hubendick, at the instance of the Swedish Department of Commerce. No less than 668 replies were received. The majority of motor owners had difficulty in getting benzol and sulphite alcohol in a state of sufficient purity, and in many cases trouble was experienced from fouling of the engines and attack of some of the metallic parts. Moreover, many of the carbureters, which were designed to use gasoline, were not properly and completely adapted for the use of alcohol, which resulted in irregular operation.

Of all the reports received only 10 per cent show the alcohol engines to work satisfactorily in every respect. On the other hand, serious trouble was reported in only 4 per cent of the answers. A most serious defect is insufficient preheating of the fuel, which results in abnormal consumption of fuel and oil and also in the deposition of unvaporized fuel which washes off the lubrication oil, and therefore results in increased wear of the cylinder walls in spite of the more liberal supply of lubricant. Incorrect adjustment of the carbureter and the ignition mechanism often leads to improper mixture conditions, incomplete combustion, and, consequently, reduced output.

In many cases there was excessive wear of parts that do not come in contact with the fuel, and this can be explained only on the supposition that the oil was also of poor quality. Some wear of engine parts was undoubtedly occasioned by the iron salts which are added during the preparation of the alcohol. The most serious disadvantage was shown to be the starting difficulty. In a general way the conclusion may be drawn from the answers received to the questionnaire that if the necessary precautions are taken the use of alcohol fuel does not affect the life of the engine detrimentally and there are no serious objections to it.

Production Value of Industrial Incentives

The big labor problem is to provide incentives in industry which will induce the worker to put forth his full capacity for accomplishment. The manufacturer must be as willing to experiment in regard to industrial relations as in regard to mechanics. Changed attitude is necessary.

By Harry Tipper

THE big problem of labor is not the problem of trade unions, I. W. W. or the radicals. It is not the question of whether the demands of the workers are justified; it is not even the question of whether they are misled by their leaders. These things may or may not be. Trade unions are wrong many times. The Socialist's dream is based upon a false idea of progress, the labor leader is no less selfish than the rest of humanity and the manufacturer is frequently arbitrary and autocratic. These things are important mainly because they indicate the amount of time lost in discussion that ought to be devoted to accomplishment.

The main job of industry is to get more work done for less cost per unit of work. Whether this work is done in the factory, in the salesroom, in the accounting department or the warehouse, the work should be planned so that useless motions and waste will be reduced to a minimum.

The big labor problem, therefore, is the production of an incentive for the worker which will enable him or induce him to put forward his full capacity for accomplishment. Anything that will aid this result is important to industry, and anything which reduces this possibility is a detriment to industry.

Obviously, the worker in a majority of cases is not putting forward his full capacity toward useful industrial accomplishment. We know that he is not as interested in his work as he might be. We know that the error in its practice is larger than it should be. Furthermore, we know that these items of waste depend for their correction upon the human element and the proper consideration of the workers within the organization.

Unfortunately, opinions have been formed from circumstances and conditions on all sides, so that people who disagree with one another as to conditions and results are contented with accusing each other of being reactionary or radical, unionists or capitalists, without getting down to the main problem.

When I was selling machinery some years ago it was a part of a salesman's aim to get the engineer to discuss some technical points about the machine, so that the main point of this disagreement would be lost sight of.

Most of our discussions upon the industrial relations has been devoted to this or that system through a union or an open shop, the bonus system or straight wage, until we have almost forgotten that the main problem of industry is production, increased efficiency and speed of accomplishment without a corresponding increase in the unit cost.

If we would get back to this point and stick to it, we would find a great deal of information to be gathered by a study of fatigue and some of the real books that have been written upon the subject. If we would look upon fatigue as something to be avoided in excess because of its effect upon production cost, our consideration of hours, surroundings and other conditions of labor would be measured from the cost standpoint.

Similarly, the question of incentive, the interest secured from the work by the worker, the encouragement to the exercise of judgment would be considered in their relation to the development of production capacity and efficiency, and from that standpoint we would find a great many suggestions in the observations of men who have no industrial management and no experience in handling a factory.

If a flexible system with more responsibility upon the foreman will improve the production efficiency within the plant, the highly centralized system is out of date, and we should reanalyze in order to eliminate its deficiencies.

In these articles the statement has been made that the work must retain the interest of the worker, in addition to the pay, if the full capacity of the worker is to be exercised upon it. As the workers increase in intelligence, it is not possible to maintain their interest in their work unless the work itself offers possibilities of mental improvement and a visibility of growth.

The interest cannot be maintained unless a fair degree of confidence can be established between the supervisor and the worker and the organization system and policy is generally understood.

The suggestions in these articles have been made because they offer possibilities of improving the individual production capacity by harnessing the human incentives to the work of production. Whether these suggestions agree with present practices as generally established is unimportant. Their agreement or otherwise with specific opinions of labor leaders, sociologists or employers is equally unimportant. The sole tests by which they should be measured are those relating to the possible improvement of production capacity and meeting the problem of constantly increasing production costs.

Either it must be admitted that the worker's interest is necessary in order to secure his full capacity or not. If this is not admitted, then the present practice stands justified as the only possible practice —with all its interruptions, troubles and fluctuations in production effort.

When it is understood that human interest in the work is a necessary part of the production capacity for maximum working value, any practice that has established a larger working value per man is worth examination and analysis so that its value may be determined and further experiments developed along similar lines.

Any manufacturer who possessed a machine which was

capable of producing more effectively, more speedily and at less cost would consider himself possessed of a strong competitive advantage and his competitors would be anxious, indeed, to secure equipment of the same character.

In human affairs it is different. Three or four hundred manufacturers in this country in various lines of industry have established experiments in dealing with the human beings in their organizations; these experiments have shown a larger production value, less turnover, elimination of wastes from interruptions and strikes, or some other greater efficiency.

Other manufacturers are not anxious to secure the information of this improved practice, however, and they are very skeptical of its value or its wisdom when they are approached upon the matter. For this reason the experimental changes in the human development of organization grow very slowly. While there is a rapid adoption of machinery which possesses marked advantages, and widespread experimentation with systems that offer new possibilities, there is little disposition to approach the human problem with the same ideas in mind. The improvement of our organization from the human side proceeds very haltingly in comparison with the improvement in its mechanics.

Not long ago a manufacturer was explaining to me a system he had developed theoretically for eliminating the trouble between capital and labor. I asked him how he proposed to put it into effect. He suggested government agencies; after some discussion we eliminated that possibility, and I asked him to try again. He then suggested that the industry might get together and formulate some plan.

We speedily discarded that, and then I said, "If you knew you could secure a piece of machinery which would eliminate a lot of your mechanical troubles and inaccuracy and save a lot of the company's money, you would feel obliged to buy it in justice to the stockholders. You have outlined a plan for human relations which you believe would lead to greater production efficiency and, therefore, more money for your stockholders. Don't you think you are obligated to put it into effect?"

"Well," he said, "maybe I am, but I cannot very well do it, because——"

In other words, this manufacturer was willing to take the responsibility for the investments of the company, the system, the methods and the operations of the company, but he would not accept the responsibility for experimentation with his human organization, although that was the only thing that made the operations valuable.

So long as this attitude prevails, experimentation will be slow, and the understanding of the human necessities within the organization will be developed to an insignificant degree in comparison with the mechanical arrangements of the organization itself.

Bait for House Organs

"WHEN you go fishing it is the taste of the fish, not your personal likes, which determines the kind of bait you use. When you publish an employees' magazine or newspaper it is the taste of the workmen that should determine the sort of material which is printed." This was the statement made recently by James Melvin Lee, editor of *Administration,* in discussing news in employees' papers before a meeting of the New York State editors of such publications.

Several other simple rules of procedure were brought out by Lee which are of interest to the executive should he desire to judge in a general way how far his employees' organ is fulfilling its function. Some of these are discussed in the following paragraphs.

News is far more important feature in these publications than are editorials. News will have a greater influence in accomplishing the purpose of the editor than all the editorials he will ever write. The employees may feel that editorials are inspired propaganda, but news cannot cause such reaction. There may be a large hole in the Main Street of your town for instance, which needs to be repaired. The local paper may write many editorials without getting any action. But if it prints a series of news stories showing how a motor truck got stuck there, how a car bumping through the hole splashed the new spring dress of one of the leading society ladies, etc., the hole will probably be patched up in a few days.

The personal element should be injected into these publications to as large an extent as possible. One Boston newspaper is said to have built up a large circulation and an excellent reputation by mentioning the name of everyone in Back Bay at least twice a year. The small events, such as marriages, week-end travels, visitors, etc., are of great interest to those concerned. The degree to which the personal element is successfully injected into the paper is likely to determine the degree of success with which it accomplishes its purpose.

To make the news interesting, the editor should be able to dramatize the facts when they are presented. Nearly all news stories when analyzed will be found to center around the idea of "struggle" in one way or another. Fires, murders, international relations, industrial relations, deaths—even marriages when they get into the news—all center around the struggle idea. It is this factor which makes the news interesting and vital to the readers. More of the struggle idea should be injected into the news stories of the plant paper, and the facts should be dramatized for the benefit of the reader.

Anecdotes and short, witty stories often help out a news account to a large extent. They liven up the article and help appreciably in dramatizing the idea. In writing their material for house organs, the editors might well take a tip from O. Henry, who is said to have stated something like this: "I just sit down and write an ordinary story. Then I put a little raisin here and little raisin there; then I put a big raisin at the end. And the editors bite on those raisins." And that is just what O. Henry did; it is the little raisins throughout and the big raisin at the end that make his stories distinctive.

Regular advertising is usually out of place in employees' magazines, but a classified column might be run to great advantage. Here the employees could be allowed to advertise free of charge anything they had to sell, etc.

There is a tendency in employees' publications to lack variety. Week after week reading of many of them leaves the reader with a sense of sameness. A proper realization of the value of news, and a proper sense of news values and methods of presentation would go far toward eliminating this fault. The employees' publication is written for the employees; not for the executives.

A Successful Convention

THE 1921 summer meeting of the Society of Automotive Engineers will go down in the history of the organization as one of the most successful ever held by the Society. Not only were the technical sessions well attended and the papers well discussed, but the meetings were handled in an alert and punctual manner which permitted of definite adherence to the schedule adopted before the meeting opened.

Those who attended the meeting were there primarily to become posted on late engineering developments and exchange information. The papers were excellent and a credit both to the Society and the authors. They furnished much data that will be used for reference purposes for years to come.

The meeting was indeed a liberal education for those who were fortunate enough to attend and will furnish much food for thought and study on the part of members who could not be present.

If any criticism is to be offered concerning the meeting it might be said that there was not quite enough time for discussion, but there was marked improvement in this direction. Some would have liked a larger proportion of papers dealing directly with design features, especially of passenger car chassis, and less leaning toward pure theory, but there was certainly no lack of interest in the subjects selected or the method by which they were treated.

The meetings committee, the S. A. E. staff, those who provided papers and discussion and others who co-operated to make the meeting so successful are to be congratulated and should receive the thanks of the membership.

The Value of Turbulence

THE idea of promoting turbulence of the mixture in an engine cylinder at the moment of ignition, discussed in the paper presented by H. L. Horning at the Society of Automotive Engineers Summer Meeting, is not a new one, but has been given far too little attention by designers and others interested in bettering the combustion conditions which obtain in automotive engines. Flame spread is greatly accelerated thereby with the result that the entire charge is burned more quickly and more efficiently. It is a well known fact that two or more spark plugs fired simultaneously at points some distance apart in the combustion chamber facilitate early completion of combustion and make possible the use of less spark advance. The same is true to an even greater extent when the flame is rapidly spread by turbulence to all parts of the charge. In this way ignition takes place at an infinite number of points almost simultaneously, and since the mixture is quickly inflamed at many points the time which elapses before the entire charge is burned is so small that the flame cannot reach the detonation velocity, and consequently the knock which would otherwise result does not occur or is much less likely to do so, at least so long as too high a compression ratio is not employed. Conversely, the greater the turbulence, other things being equal, the higher the compression ratio which can be employed and the higher the efficiency obtainable.

Mr. Horning points out two methods for obtaining turbulence and shows the advantages gained thereby. His paper is worthy of careful study and should prove instructive even to those who are already well versed in the subject.

Hub Standardization

NOW that the smoke of battle has cleared away and the adoption of the recommended practice on front truck hubs is an accomplished fact, a real panorama of the admirable way that the Standards Committee of the S. A. E. has handled a difficult problem is presented.

It will be remembered that this matter was referred back to the committee at the meeting last January after failing to carry by a very small majority. The ball bearing manufacturers, and doubtless rightly, believed that their side of the case had not had the proper consideration. Subsequent revision of the recommendations have met with the en-

tire approval of all concerned and as a result the report was carried unanimously.

AUTOMOTIVE INDUSTRIES congratulates the standards committee and members of the ball and roller-bearing industry, the axle manufacturers, wood and metal wheel manufacturers and other allied interests on the unselfish co-operation which finally made this result possible. Having vigorously pointed out in its editorial pages the economic waste through lack of uniform practice due to minor and immaterial differences, this publication looks forward to the rapid adoption of a similar report covering front hubs for passenger cars, as a real conservation measure and one which will further the welfare of the entire industry.

Scientific Research

AT the S. A. E. meeting one of the speakers made the remark that during the period of from 15 to 10 years ago a great deal of scientific research on problems connected with the operation of internal combustion engines was carried out in England by such men as Clerk, Hopkinson, Callender, Bairstow, Watson and others, while at the same time in America little attention was given to such matters; now things seemed to have changed around, for aside from the creditable work of Ricardo little research is being carried on in England, whereas in the United States the subject is being taken up with avidity. Prominent among the scientific work on gas engine phenomena being done in this country is that of the Bureau of Standards and of the Research Laboratory of the General Motors Co.

Research work, so far as it pertains to internal combustion engines, may be divided into two classes, namely, research carried on with a view to the solution of immediate practical problems and research conducted with a view to establishing broad fundamental facts without special regard to their immediate practical application. Research of the former kind has been carried on in America practically ever since the automobile industry was first established. It was often conducted with limited means and meager equipment, and the results obtained were seldom published. The making and testing of all classes of experimental devices intended as models for manufacture falls under this head. It must be realized that if a new type of carbureter, for instance, is developed, numerous experiments usually have to be made before all around satisfactory results are obtained, and this experimental work really constitutes research, although it passes more generally under the name of development work.

The work done in England by such men as Hopkinson, Bairstow and Watson was of a different character. Most of it was conducted for the Gaseous Explosions Committee of the British Association for the Advancement of Science. Among the factors determined experimentally were explosion temperatures, changes in specific heats of the products of combustion with temperature, rate of flame propagation, chemical constituents of exhaust gases, etc. These are fundamental factors in the operation of engines, and a knowledge of them undoubtedly enabled engineers to design better engines. The results then obtained are probably appreciated a great deal more now that the necessity of exceeding high speeds and of burning the heavier grades of fuel has confronted engineers with new and more difficult problems than when they were first made known to the public.

If research on internal combustion engines is lagging in England just now, we need not expect that this will remain so for any length of time. Immediately after the war a national research organization was created there for the purpose of encouraging those industries which felt that they could benefit by systematic co-operative research work and were willing to contribute the necessary funds by the grant of Government research subsidies. One of the industries that have qualified for such grants from the Treasury is the automobile industry. Naturally the result of this research work will not be published generally and will be made available only to such firms as contribute to the fund required for meeting the expenses. Also, the work will no doubt be carried on more with a view to immediate practical returns and will therefore be conducted on materially different lines from that of the Gaseous Explosions Committee.

The Individual in Industry

THE question of incentives in industry is often approached from the wrong side. Plans for making workers more enthusiastic about their jobs and consequently more efficient are likely to start by viewing workers as a mass. Actions of "Labor" are considered and the plans devised are formulated on the mass basis.

It is probably true that certain fundamental principles form the basis for human actions and reactions, but at the present time we are far from understanding what these fundamentals are. We cannot hope to understand them except through a long period of conscientious study and experiment. And the analysis of the problem must center about the individual—not about the mass.

The mass is simply the group of which the individuals form the component parts. It can never be understood until the individuals are understood. We must start our work and study with the individual. Industrial relations should be approached from this angle if permanent progress is to be made.

To study human relationships in industry by concentrating on the individual is a tremendous task. Progress is likely to be slow; but once made the progress is permanent. To attempt to solve the difficulties through formulas and mass generalities is to put the cart before the horse.

Though a slow process, the analysis of the individual is really the quicker, because it will record constant progress, while the mass approach leads backward rather than forward. And this constant progress will more than pay in production and profits, as it goes along, the expense and trouble necessary for the analysis.

Americans Sweep Indianapolis Race

Milton's Frontenac Leads Contenders

Eight of First Nine Places Go to Yankee Cars—Engineers Analyze Results

INDIANAPOLIS, May 30—A Frontenac car, piloted by Tommy Milton, won the 500 mile classic here to-day and was closely followed by three other American cars. The second car was a Duesenberg straight-8 special. Third was the Chicago Frontenac and then another Duesenberg. Only nine laps separated these cars when the winner crossed the line. The fifth car was a Sunbeam. Only nine cars completed the race. Continuing in order they were: Duesenberg, Leach special, Duesenberg and a Frontenac.

The drivers in the order in which they followed Milton across the line were Ralph Sarles, Jules Ellingboe, substituting for Percy Ford; Jimmie Murphy, Ora Haibe, Bennett Hill, Ira Vail, Albert Guyot, and Ralph Mulford. The tenth prize was distributed between the drivers finishing the race.

At the beginning of the race, De Palma made a splendid record with his Ballot special for 102 laps. He kept the time well above 93 miles an hour while he was in the running and he carried off something more than $10,000 in lap prizes.

After he went out Sarles took the lead for a time, but Milton soon came to the front and led consistently. Milton's time was 5:24:44.65. His average speed was 89.62 miles an hour, which compares with last year's average of 88.50. Both of these races were for cars of 183 cu. in. displacement.

The track record is 89.84 miles an hour, made in 1915, when 300 cu. in. was the maximum. The Frontenacs are practically the same as the Monroe, which won last year.

Duesenberg Team Work Good

Milton's victory was a reward for good driving of a good car. The Duesenberg group always had some one handy to spurt with De Palma as long as he remained on the track. It is held that De Palma was led into unwise bursts of speed by the splendid teamwork of the Duesenberg group.

While all the deserved glory goes to the victors, it is really those who fail who make the Indianapolis classic of value to the industry. Indeed, for these cars to have run and lost is far better than had they not run at all. Each broken hope, in the form of a shattered part, spells out an engineering lesson which, when interpreted, makes the Indianapolis Speedway the greatest automobile engineering school in the world.

HOW THEY FINISHED

First, Tommy Milton	Frontenac
Second, Ralph Sarles	Duesenberg
Third, Jules Ellingboe	Frontenac
Fourth, Jimmie Murphy	Duesenberg
Fifth, Ora Halbe	Sunbeam
Sixth, Bennett Hill	Duesenberg
Seventh, Ira Vail	Leach Special
Eighth, Albert Guyot	Duesenberg
Ninth, Ralph Mulford	Frontenac

Time of winner: 5:24:44.65. Average speed: 89.62 miles an hour.

When Tommy Milton piloted his Frontenac special to victory he bore out his reputation for being able to size up the staying qualities of his vehicle and his wisdom in not exceeding the pace which eventually proves to be sufficient to win. Too fast a pace was set up by others, probably in an endeavor in some conspicuous instances to win prizes for laps. Ralph De Palma won every lap prize except two up to the 110th, but this burst of speed, which was far ahead of all previous records for the distance, probably cost him the race as he went out on the 111th lap with a burned out rod.

Next to tire stops, which in spite of the hot weather were less numerous than in any previous year and mostly merely precautionary at that, burned out rods and spark plugs were the most prolific causes of trouble and equal in number, there being four cases of each.

Next in order came steering knuckles and water connections with three instances of each. Freezing brakes, valves, ignition and oiling each claimed one victim. As far as the broken rods were concerned, it is more than likely that the trouble with some of these originated in clogged or faulty oiling systems.

Those who suffered were Ralph De Palma in his Ballot special, which looked for a while like an easy winner; Howard Wilcox in the Peugeot, first out of the race; the Talbot-Darracq and one of the Junior specials.

Five Spark Plug Victims

Spark plug troubles were experienced by the Revere, Ballot, Boyer's Duesenberg, Spiel, and Murphy's Duesenberg Special. Those who had the plug troubles had many of them while the others had none at all so that it is very possible that the troubles were of design. Perhaps it was the old fault of not enough water around the plugs.

Two of the Duesenberg specials had broken steering knuckles, showing possibly a weakness in heat treating or material selection. Both cars and drivers, Murphy and Thomas, had narrow escapes as their cars went from one retaining wall to the other, creating conditions with

Miller Encourages Loans on Car Paper

Kansas City Reserve Head Opens Way to Business—Funds Now Ample

KANSAS CITY, May 31—Two items of motor car paper, said to be paper of distributors of motor cars, submitted by member banks, were rediscounted by the Federal Reserve Bank of Kansas City, during the week of May 23.

Governor Miller of this Federal Reserve Bank sent letters to several of the member banks, announcing that high class motor paper that is solvent and eligible, was being taken.

Governor Miller's most emphatic statement, in the course of an interview with a Class Journal representative, was a declaration that the Federal Reserve Bank of Kansas City is now offering rediscount facilities on automotive paper primarily and definitely for the benefit of automotive dealers and distributors of the Tenth Federal Reserve District.

"We are hoping," said Governor Miller, "that our increased liberality toward motor paper will not cause a flood of that paper to invade the Tenth District and absorb the lending power of the leading banks as well as of the Federal Reserve Bank, which ought to be used for promotion of live stock interests. We are hoping that such automotive paper as is offered, by member banks, will be paper of firms and individuals of this district, in the automotive business, and not paper of outside automotive concerns."

In 1920 a great deal of outside motor paper from the automobile and accessory field was bought as commercial paper by Tenth District banks. Most of this was liquidated as it matured and has not been returned to Tenth District banks. None of it, of course, got into the Federal Reserve Bank. It is obviously the desire of the Federal Reserve Bank officials, that each automotive district take care of its own automotive paper.

Has $40,000,000 Reserve

Several factors, not mentioned in his address to the Motor Car Dealers' Association May 21, seem to have entered into Governor Miller's decision to relax the scrutiny of commercial paper. The Kansas City bank is $70,000,000 better off this spring than in the spring of 1920. Then, it owed $30,000,000 to other District banks; that is paid off, and the bank has accumulated a large reserve.

An important factor is the sharp contrast in the attitude of bankers gener-

Industry Steady as Market Changes

Renewed Sales Follow Reductions in Price

No Repetition of 1920 Slump Likely—Farm and Foreign Markets Opening

(By James C. Dalton)

NEW YORK, May 31—The present decline in buying demand for automobiles is neither remarkable nor unexpected. In fact, if there had not been a falling off in sales at this time it would have been most remarkable. The business of companies which have announced definite price reduction is holding up remarkably well.

There probably are many elements responsible for slower buying. One of the most important is uncertainty in regard to prices; another is the usual seasonal slump, and another is bad weather. Spring sales began earlier than usual this year and it is only a natural sequence that they should slow up earlier. The slackening demand did not come unexpectedly to anyone in the industry who has followed the situation closely. There always has been a dull season in summer for the automotive industry. There are few industries which do not have dull seasons.

In recovering from periods of depression, industry and commerce always have ups and downs. There is no steady upward trend, with business increasing each month, nor does trade remain stationary. But business seldom slumps back as far as it did at the height of the depression, and each rebound carries it a little farther forward than the last one. That undoubtedly is what will happen now with automobiles.

Sales Pace Production

It is not likely that sales—and sales now are synonymous with production—will drop back to the low levels of the last months of 1920 and the early days of 1921. Trade will depend to a greater extent than it has since March upon general business conditions. These should show a marked improvement by early fall. Predictions in times like the present are foolhardy, but it can be said safely that there are more elements tending towards stability than there have been since deflation began a year ago.

The general buying power of the country has now approached its lowest ebb, except for those unfortunates who have been compelled to draw on their savings to meet current expenses. The outlook is brighter now than it has been in years for those with fixed incomes and for the salaried workers whose positions are secure. They are finding the purchasing power of their dollars constantly increasing. There are many thousands of families in this class who, if they are not now in a position to buy an automobile, soon will be. The difference between their earnings and their expenses is steadily widening as the cost of living slowly but surely declines. These families are the ones which make the best prospects.

Industrial Conditions Spotty

Industrial conditions throughout the country are "spotty" and they will continue to be for some time to come. There is less depression in some districts than in others, and those sections which are most prosperous naturally offer relatively the best sales territory. Intelligent sales efforts will bring results now as they always have. The wiser sales executives are not mapping out arbitrary campaigns and sticking to them. They are keeping their forces mobile and making quick, decisive raids in the districts where the most money is to be found.

Sales resistance in the great agricultural sections is slowly breaking. It cannot be said truthfully that the farmers are buying feverishly as yet, but they are displaying increasing interest in what they consider real bargains. This is shown by the greater volume of sales reported by the great mail-order houses which find their best patronage on the farms. Holdings of last year's crops gradually are being turned into cash and the outlook for the present season is most encouraging. By fall the buying appetite of the farmer should have been whetted to such an extent that he will consider purchasing the motor vehicles he sorely needs.

Domestic business is inextricably bound up in foreign trade, and in this direction there are distinctly encouraging factors. Chief of these is settlement of the German reparations question and the evident sincere desire of the present German Government to meet its obligations scrupulously. A better feeling already is apparent in Europe. The Silesian question probably will be settled without further bloodshed and the justifiably militant attitude of France has been modified to meet the Teutons half-way, if it finally is demonstrated that they intend to meet squarely the burdens imposed upon them for drenching the world in blood.

Reparation Treaty Helpful

The stabilizing effect of the reparations settlement already is apparent upon the continent, and European nations soon will be coming into the market for the purchase of American goods

Argentina to Take Cars in September

Will Clear Present Stocks by New Season's Opening—Ford Manager Resigns

NEW YORK, May 27—Contradictory statements concerning the automotive situation in Argentina are cleared up and the promise held out that new business will be gotten under way in time for the opening of the sales season in September, in information received from M. T. Meadows, manager of the American Chamber of Commerce, Buenos Aires. This observer declares that the stocks of cars held in the Argentine on May 3, when his communication was written, represented no more than a two months' normal supply.

"I feel that I can assure you that the friendship and goodwill of the Argentine dealer and importer is not lost," Meadows states, "so that the resumption of the sale of American cars on a large scale is merely contingent upon the revival of business activity here.

"In effect the large car stocks, reported in a previous statement, are gradually being liquidated and are now figured as standing at about two months' normal supply. However, owing to the general business depression still prevailing, which is reflecting most unfavorably in the automobile market, it is probable that the present supply will carry us through the winter and very few new cars will be needed until the opening of the spring and summer selling season in the coming month of September.

"I also feel sure that our American manufacturers have shown a ready disposition to get together with their local dealers and that eventually the situation will adjust itself in a manner satisfactory to all concerned."

The resignation of E. H. Hampton, as manager of the Ford branch at Buenos Aires, also is reported, as one of the results of the change of dealership territorial rights, similar to the changes made in this country several months ago. This action in taking away the exclusive territory rights has evoked a storm of protest from the Argentine agents who number about 325. Hampton became the Ford manager at Buenos Aires in 1912, when Ford sales were 30 yearly.

COLUMBUS TIMKEN RESUMES

COLUMBUS, May 31—The Columbus branch of the Timken Roller Bearing Co. has now 260 men on its payrolls and additions are being made constantly, according to Charles N. Replogle, general manager.

Ace Truck to Sell Direct from Factory

Elimination of Dealers, Company Says, Permits Price Cuts of $455 to $655

NEWARK, OHIO, June 1.—The American Motor Truck Co., manufacturer of the Ace truck, has eliminated distributors and dealers from its selling plan and hereafter will distribute its product direct from factory to user through a system of zone offices. Coincident with the change of policy, the company has announced a reduction of $455, or 16½ per cent, on the 1½ ton model and of $655, or 23½ per cent, on the 2½ ton model. The new prices are $2295 on the 1½ ton and $2795 on the 2½ ton.

The new Ace plan, originated by C. L. Bowler, general manager, was first tried out beginning Feb. 1. In 60 days in three zones where the test was made, 396 garagemen were retained to handle the service work and these garagemen, operating on a basis whereby they will be paid $150 each for names of prospects who later buy trucks, turned in more than 1400 prospects. Up to date 14 zone managers, recruited from the ranks of factory and distributor sales representatives of various truck lines, have been appointed and it is planned now to develop the new selling system on a national scale under the direction of Glenn B. Hiller, who became general sales manager May 1. Hiller formerly was general sales manager of the Nelson Motor Truck Co. and later assistant general manager and director of sales and advertising of the Triangle Motor Truck Co.

The Ace will develop new selling zones gradually by sections throughout the country, eventually, according to the present plan, having between 200 and 300. In each will be a zone manager in charge of sales and service, a zone service supervisor and as many salesmen and traveling service men as are necessary. The zone managers and their assistants will all be factory employees, those in the sales department working on commissions with drawing accounts.

Will Have Service Depots

It is planned in each territory to have a central parts depot or two or three if necessary, and 200 or more service stations handling monthly inspections of all Ace trucks in the territory and doing necessary repair work. These service stations will also obtain prospects for new truck sales. They will be allowed $150 on each prospect who later buys and they will be permitted to get the cooperation of drivers and others to obtain prospects in which case $50 of the $150 will go to the tipster. Selling will be handled exclusively by the zone manager and his salesmen.

Service stations will make no investment in parts, obtaining these as needed from the zone parts depot, which it is expected in most cases will be not more than 25 miles distant. The zone service man will check up the service station on the quality and prices charged for repair work. For the inspection service, which includes four inspections of three hours each the first month after a truck is delivered and one of three hours each month thereafter for 11 months, the service station will receive $45 from the factory, this inspection being free to the owner. The owner carries a coupon book entitling him to the inspections which he can obtain in any garage serving as an Ace service station. Garagemen for this work will be selected preferably from those having no car or truck agencies.

The company will do no trading but through its zone managers and service stations will sell used trucks for new truck buyers on a commission basis. New trucks will be sold for 50 per cent down and the balance in six months, the American Motor Truck Co. doing its own financing. In the contract will be a provision under which the owner pays a flat rate of $150 on the 1½ ton truck and $182.50 on the 2½ ton truck for interest on the time payment over the six months period and for insurance on his truck for one year.

The company states that the reductions in its list prices were made possible through the reduction in selling cost under the new plan.

Louisiana Motors Head Temporary Receiver

SHREVEPORT, LA., May 31—Acting upon application of creditors who hold notes against the Louisiana Motor Car Co., W. F. French, president of the company, has been appointed receiver by the court according to the petition asking for receivership. The unpaid debts of the concern amount to approximately $150,000 with assets amounting to more than $900,000.

The appointment of a temporary receiver to manage the affairs of the company whose automobile factory is located at Cedargrove, near Shreveport, was agreed upon at a meeting of the board of directors. At the request of the petitioners, W. F. French, president of the company, was appointed by the court as temporary receiver. The only reason given for the request for the receivership is that the company owes debts which it has not the means available to pay. The factory has been temporarily closed down, but it is announced will resume operation soon.

DART TRUCK IN RECEIVERSHIP

WATERLOO, IOWA, June 1—To avoid complications following the death of President C. C. Wolf of the Dart Truck & Tractor Corp., who was also cashier of the State Exchange Bank, W. H. Johnson, former vice-president and general manager of the company, has been appointed Dart receiver and will continue the business. The company's inventory of materials for trucks and tractors is declared to be in excess of its obligations.

Penn Motors Names Trucks for Dealers

Applies Brand Idea to Commercial Vehicles—Will Make Passenger Car Later

PHILADELPHIA, May 28—Something distinctly new in the policy of truck manufacture is in operation at the new factory of the Penn Motors Corp., Rivington, N. J., whose headquarters for sales is in this city. Hilton W. Sofield, president of the corporation, said the corporation will manufacture Penn trucks for the dealer, this being an application of the brand tire idea to trucks.

While the product of the factory will be generally known as Penn trucks of two tons' capacity, the corporation, as a special inducement, and having in mind the benefit of the dealer, will, where the dealer prefers it, have the trucks made with his name on the radiator and rear, exactly as if they were manufactured by him, thus not only advertising the dealer, but also giving the truck for that territory an individuality. There are certain restrictions, however, where the dealer's name is used.

Already orders for more than 100 trucks have been received and it is expected that the first will be finished within six weeks. There is one large building, 80 by 220 ft., in use at the factory, with several small outbuildings. It is planned to manufacture a light delivery truck in time, and before long the matter of making a passenger car will be taken up.

Speaking of his new plan, Sofield said:

"We had in mind making it easier for the dealer, who very often, just after he has succeeded in working up a good business, is informed by the factory that he will be removed from the territory and a branch factory established at that point, 'because business seems to warrant it.' Usually this business has been made possible by the man who, in such a case, has to suffer for it, instead of being rewarded."

The officers of the Penn Motors Corp., which is incorporated under the laws of New Jersey, are: Hilton W. Sofield, president; Howard S. Sofield, treasurer, and Charles B. McGuire, secretary. The directors are the foregoing and Dr. W. W. Beveridge, L. H. Collins and George A. Small.

The authorized capital stock is $300,000.

REVERE SEEKS $1,250,000

LOGANSPORT, IND., May 31—The financial condition of the Revere Motor Co. remains almost unchanged. The necessity of selling $1,250,000 of stock for refinancing and placing the factory in production is admitted to be considerable of an undertaking. It is practically certain that the money cannot be obtained in Logansport, despite the fact that quite a few prominent Logansport men have gained control of the crippled organization.

War Gave America World's Tire Trade

British Manufacturers, Seeking Protection, Declare United States Far in Lead

LONDON, May 6 (By Mail)—Urging protection for the British tire industry, the British Rubber Tire Manufacturers Association, Ltd., has prepared a memorandum in which it outlines the precariousness of the situation caused by American imports, unfavorable exchange rates and loss of Continental markets. The memorandum says in part:

"The rubber tire manufacturing industry in Great Britain is assailed by severe foreign competition, which is having a most serious effect on the industry. A great deal of this competition is from the United States, where, owing to overproduction, the home market is overloaded with tires, and the remainder from Continental countries with a depreciated currency. It can, therefore, hardly be classified under the heading of 'dumping' in the usually accepted sense of the term. The effect of this foreign competition at home and abroad is already felt to such an alarming degree by British manufacturers, and the position is so serious, both to the employers and the workpeople engaged, that unless immediate protective steps are taken the industry will be gravely affected.

"Before the war, although subject to fairly keen competition from France and Germany, the British tire industry did not experience any serious competition from America, and, generally speaking, was able to hold its own. In motor tires particularly, a branch of the business which was then attaining large dimensions in the United States, the American manufacturers had failed to make any effect on British home and Colonial markets, and in many Continental and foreign markets where the British manufacturers had a strong hold.

"The importance of the tire industry to the nation cannot be over-estimated. Motor transport is impossible without tires, and a state of affairs in which the nation had to rely upon foreign supplies in time of war would be unthinkable.

War Service Important

"The important part played by the British tire industry during the war cannot be over-rated. Under circumstances of extreme difficulty it supplied not only the requirements of the British armies, but assisted largely in supplying those of our Allies on all fronts. Prior to the war solid tires for heavy vehicles had been almost exclusively supplied by Germany, and British tire manufacturers were, therefore, faced, on the outbreak of war, with the necessity of overcoming the technical difficulties involved in solid tire construction, and that they were successful is demonstrated by the fact that at no time was transport held up through lack of tires.

"During the war practically the whole output of the British tire manufacturers was taken by the Government. This position gave considerable advantage to American competitors, who, until the last year of the war were unfettered in any way by war restrictions and were thus enabled successfully to attack the British home and export trade in motor tires. This export trade of the British manufacturers had been secured at great effort and expense, and war conditions therefore presented American firms with the goodwill of the British tire manufacturers in the various foreign and Colonial markets. American firms who, prior to the war, exported little or nothing are now doing a considerable export trade.

Imports Rise Ten Times

"The tire imports into this country from the United States of America rose from £231,096 (for the year ending 30 June, 1914) to £2,097,215 in the year ending 30 June, 1916, while in the Colonies and eastern markets, where motoring restrictions were less marked, their success was even greater.

"It was only half way through 1917 that their progress in this country was, to some extent, checked by import and shipping restrictions, but the hold secured by the American trade means that their competition has become an after-the-war factor, which presents a very serious menace and a much greater one than any the industry was faced with in pre-war times.

"The Americans have a huge home market which is fully protected by tariffs, while, on the other hand, it is necessary for British manufacturers, with their small home requirements, to be in a position to do a large export trade, and their activities in this direction are seriously curtailed by the advantage gained by the American manufacturers at a time when the whole of the British production was required for war work.

"The rapid rise of the American rubber industry is shown by the fact that in 1914 the production of rubber goods in America was to the value of £60,000,000, and in 1919 this had risen to £240,000,000. About 75 per cent of the total production consists of tires, and, therefore, the approximate value of the output of tires produced during 1919 would be £180,000,000. This export of tires from the United States rose from £788,644 in 1913 to £4,493,316 in 1919, and the export figures available for the current year show values at the rate of £10,000,000 per annum.

Eliminate Special Taxes

"Most of the important American concerns have their own subsidiary British distributing companies, and it is understood the prices at which tires are charged to the branches in this country are so arranged that no profits are shown for income tax purposes or excess profits duty.

"There are now very large stocks of British tires abroad, foreign demands have practically fallen to nil, and British manufacturers are faced with such

(*Continued on page* 1181)

New Japanese Tax Blow to Car Sales

Fees of 1920 Increased 50 to 80 Per Cent—Opposition May Bring Decrease

SEATTLE, May 27—Prospects for the future development of the American trade in motor vehicles in Japan have been dealt a severe blow by the enactment of new prefectural and municipal tax laws on automobiles, motorcycles and motor trucks, which call for excessive fees from owners. Great opposition is developing in Japan to the new taxes and it is hoped that they will be modified.

The new taxes represent an increase of from 50 to 80 per cent on the taxes in force last year. Coming, as it does, at a time of marked business depression in Japan, it cannot fail to have an adverse effect on the automobile business.

On privately owned vehicles of from one to five horsepower the new tax totals a yearly expenditure of 135 yen ($67.50). From five to ten horsepower the total is 229 yen, ($114.50), and from 10 to 15 horsepower, 378 yen ($189).

By far the greater majority of motor cars are rated in the 15-30 horsepower class, and it is in these classes that the taxes are the heaviest. For privately owned vehicles of from 15 to 20 horsepower the tax amounts to 598 yen ($299) per annum, and from 20 to 25 horsepower the very sizable figure of 843 yen ($421).

On the average, the motorist of Japan will be obliged to pay a municipal and prefectural tax aggregating 10 per cent of the first cost of the automobile. The average car of 25 horsepower retails in Tokyo at approximately 8500 yen ($4,250) and the owner of such a car will be assessed for an annual tax of 843 yen, or approximately 10 per cent. The cost of upkeep, including tires, fuel, oil, repairs and garage hire in Japan is very high, and the addition of the new tax will render motoring well-nigh prohibitive, declare Japanese dealers.

The tax on vehicles in commercial use is smaller, but nevertheless very high, taking into consideration the work in which these vehicles are employed. From one to five horsepower, the tax is 70 yen ($35) a year; from five to ten horsepower, 78 yen ($39), and from 10 to 15 horsepower, 127 yen ($63.50).

The new tax is based entirely upon the horsepower rating of the motor vehicle, and does not take into consideration the age of the car, the first cost, or the probable re-sale value.

GERMANY CUTS PRODUCTION

NEW YORK, June 1—German automobile works are suffering a further reduction in demand, according to reports reaching here. Operations have been cut to a minimum as they have in many of the Rhenan-Westphalia iron works.

Industry Steady as Market Changes

Financing Export Sales to Help Crop Regions—Falling Market to Continue

(*Continued from page* 1177)

upon a moderate scale, provided long-term credits can be extended. This is a pre-requisite to foreign trade. Sales of goods abroad inevitably will relieve depression at home. Those companies which have cultivated foreign customers carefully and wisely soon will begin to reap the harvest of their forethought.

Arrangements are now being made for financing export sales of foodstuffs, cotton and other commodities. This will thaw out frozen credits in the South, Middle West and Northwest, thereby putting into circulation money which can be used to buy finished products. The emergency tariff, framed especially for the benefit of the farmer, probably will tend to slow up exports, but its full effect in this direction cannot be determined immediately. It is not likely its deterrent effects will be strong enough to prevent a steady increase in exports.

Haphazard sales efforts are no more advisable in foreign trade than they are at home, and the companies which study their markets carefully will get the most business. Advices from Argentina, for example, state that the large surplus stocks of automobiles in that country are being gradually liquidated and it is probable dealers will be in the market again by late fall. The same conditions undoubtedly prevail in other countries. On the other hand, there is little hope of any extensive business with England for months to come, although some of its colonial possessions are well worth cultivating.

The United States as a nation is comparatively young industrially and it has not become inured to hardships and adversity as have some of its older sisters. For that reason it is rather temperamental. It either is riding joyously on a high tide of prosperity or it is in the slough of despond. There apparently is no mental middle ground. Times are hard now, largely by contrast with the unexampled prosperity of the war period. An enormous amount of business still is being done and the present volume of employment would not have caused serious alarm in the years prior to 1914.

Deflation Hopes Ill Founded

Any hope that recovery from war inflation would be rapid was ill-founded. It is vastly easier to spend money than to save it, and it takes much less time to burn up capital than to build it. Some of the wealth destroyed in the war must be restored before there can be any real progress toward what may be considered normal conditions. This applies not only to this country but to every nation in the world.

For that simple economic reason the process of recovery will be painfully slow and it will be attended with many difficulties. The business structure of the country is gathering strength, and the gains from now on never will be quite offset by the losses, so that recovery is assured.

Business will be done on a falling market for many months to come and its stabilization will be marked by a survival of the fittest. Falling markets do not necessarily mean hard times, however, and faith in the future will be abundantly rewarded. A long period of prosperity is before the United States and there is every indication that it is approaching with all the speed that can be expected under the circumstances.

Blame Backward Spring for Sales Resistance

MILWAUKEE, May 31—Shipping instructions from distributors and dealers have assumed a more satisfactory volume, with the result that the recent accumulation of finished jobs in factory warehouses is steadily being eliminated. The operation of factories is expected to resume an upward swing momentarily. From the middle of the month to date nearly every passenger car manufacturer felt the effect of a sudden recurrence of sales resistance due principally to the backward spring, which jammed the flow of cars from producer to dealer. The arrival of seasonable temperature, however, has loosened the congestion.

The automotive parts and equipment industry in Milwaukee did not slow up to nearly the same extent as passenger car production, although some plants have noticed a tendency on the part of manufacturers to cut down delivery specifications on contracts for engines, frames, axles, etc., because smaller quantities were required currently. No perceptible reduction of working forces in parts shops has been made, although production schedules were curtailed to some extent to prevent undue accumulation at the source.

COTTON ACREAGE REDUCED

NEW YORK, June 1—Reductions in cotton acreage for 1921, together with a reduction in use of commercial fertilizer, give an estimated yield of 7,558,365 bales for 1921, according to American Cotton Association figures. This yield is still further reduced to 6,762,664 bales by allowances for abandoned acreage after planting and other minor losses. The average production for the past five years has been 11,808,389 bales. The acreage for the current year will total approximately 24,563,486, conforming very closely to the acreage planted in 1897, which totaled 24,319,584.

WILLYS LIGHT JUNIOR, $295

TOLEDO, June 1—The Willys light division of the Electric Auto-Lite Corp. is now manufacturing a small individual lighting plant for use on farms, which will be known as the Willys Light Junior. The new plant, which sells for $295, has a generator rating of 500 watts.

Chicago Bank Finds Lower Prices Needed

Process of Liquidating Inventories at High Costs Slow and Difficult

CHICAGO, June 1—While general manufacturing shows little change in the past thirty days in the Middle West section, the disposition of manufacturers being to operate on a hand to mouth basis, buying only those materials that are necessary to fill outstanding orders, there are evidences of a gradual stabilization of business conditions.

The Federal Reserve Bank of Chicago finds that "business is going through a process of 'backing and filling' as a result of the effort to liquidate stocks purchased at higher prices, and to replenish at the new market level lines of merchandise as they are exhausted."

The advent of warm weather has gone a far way toward changing the mental attitude of the farmer although the farm implement business still remains practically at a standstill. One of the large implement manufacturers has closed down virtually all of its plants; another is operating on a schedule about 35 per cent of last year and nearly all implement manufacturers have a sufficient stock of finished products on hand to meet the ordinary demand for some months in the future.

In the manufacturing centers trade continues in a surprisingly good volume with indications of a movement of merchandise in those centers where industries experienced a sharp slump around the end of the year. Collections show no uniformity, the situation seeming to turn upon the ability of business men to liquidate their inventories.

Lowering of the cost of labor and a tendency to greater efficiency are showing themselves in some of the larger cities of this section. One outstanding feature in the motor car industry, as in other lines of business, is that those who are showing courage in the conduct of their business by forging ahead and manufacturing or using up high priced materials on hand and replenishing at lower costs are finding a ready market for their products, even though it be at reduced prices; while those who have adopted a more conservative policy of manufacturing are necessarily liquidating their inventories more slowly, and consequently are experiencing more difficulty in working out of the condition in which they found themselves.

Used Car Market Limited

A factor from the dealers' standpoint is that there is a more limited market for used cars, due to unemployment and general depression. Accordingly, the dealer finds his capital tied up in these cars and is unable to make further sales, involving trade, until he has liquidated such stock. Many of the steel contracts to automobile companies contain adjustment clauses.

War Gave America World's Tire Trade

British Market Now Using 75 Per Cent Imports—Would Apply Equalizing Duty

(*Continued from page* 1179)

competition from Continental manufacturers as will necessitate the liquidation of stocks at a loss in very many cases and the closure, in due course, of such markets in Italy, France, etc.

"If the import of tires at the present rate continues they will cover 75 per cent of the total motor tire requirements of the British home market.

"In addition to the disadvantage of the currency rates the British manufacturer also suffers from the cost of his product being increased by the heavy duty on imports of tires into foreign countries. In the Canadian and American markets, where the exchange rates favor the British, it is impossible for them to take advantage of the position as in those countries a different type of motor pneumatic tire came into general use during the war, and it has not yet been possible for the British manufacturers to obtain the necessary plant to enable them to meet the demand for this type of tire owing to war restrictions.

"The following remedies are suggested for consideration:

"(a) The limitation of future imports and the treatment of foreign stocks on hand in England as 'future' imports.

"(b) The levy of a duty on future imports on the basis of the difference between wages and local expenses per article in the country of origin at the rate of exchange current from time to time and the wages and local expenses per article of the British manufacturer.

"(c) The influencing of British Dominions to investigate and confirm whether British manufacturers actually have a tariff preference over foreign manufacturers in view of the depreciation of the various currencies, and, where necessary, the adjustment of such tariffs."

Tire Cuts in Belgium Check American Sales

NEW YORK, June 1—American tire trade in Belgium has been severely affected by an unprecedented wave of price cutting entered into by many of the leading domestic manufacturers and producers in England and on the Continent. The price cut has been so extensive that one of the large American companies has recalled its agent, being unable to compete successfully under the new conditions.

The questions of credits and exchange rates have also been important factors in the problems affecting American manufacturers. Opposed to the American policy of demanding cash in advance or payment against documents is the long term credit offered by German makers and now adopted by at least one important French company. To get business in Belgium it is borne to American manufacturers that they must make every effort to meet European competition with more acceptable terms.

Good business is reported in some American brands which are being offered at prices in francs near the European level. Buyers of low price tires do not lay stress on mileage as long as the price is what they think they should pay.

MAY SALES FALL OFF; JUNE OUTLOOK DULL

NEW YORK, May 31—Automobile production for the month of May reached approximately the same figure as in April but there was a material falling off in sales in practically every section of the country.

The most notable exception was in the South where business showed an improvement for the first time in many months. This was due to gradual liquidation of the cotton crop in preparation for the sale of the new crop.

Retail business in New York and the metropolitan district remained fairly steady and approximated that for April.

Reports from the great agricultural sections show that while business in May was not as good as in April a marked improvement in sales is expected when harvesting of the crops begins.

Nearly every section of the country reports that lines which have cut prices are doing a good business and that there is every indication sales will continue brisk.

General indications are that both production and sales in June will be considerably below May. The cry of dealers everywhere is for price stabilization by definite announcements by manufacturers of what they intend to do.

AJAX BUILDS NEW TIRE

NEW YORK, May 27—Following its reduction in prices which became effective two weeks ago, the Ajax Rubber Co., Inc., is soon to bring out a new cord tire developed by William W. McMahan. The new tire is now in production at the factories in Trenton, N. J., and will be placed on the market at once.

SHERIDAN SALES UNCHANGED

REDWOOD CITY, CAL., May 27—Capt. Eddie Rickenbacker, who is here to-day supervising the preparation of the army field for his flight to Washington to-morrow morning, stated that the purchase of the Sheridan Motor Car Co. by the Durant interests would not affect the Sheridan on the Pacific Coast and he would continue active management.

Steel Tread Tires Pass Out in France

Surplus Army Stocks Factor in Swerving Former Demand—Clincher Type Favorite

PARIS, May 14 (By Mail)—Steel studded automobile tires, which only a few years ago were considered absolutely essential for safety, are rapidly passing out of use in France. It was formerly common practice to run with steel studded tires on one rear wheel and the opposite front wheel, under the impression that this combination alone gave a guarantee against skidding. In London, taxicabs are bound by law to be equipped in this way, and although there was no such legal obligation in France, the practice was generally followed by owners. Customers taking delivery of a new car claimed at least one steel studded tread.

The general practice now is to supply all new cars with rubber tread tires, the public accepting these without objection. This change is bringing France into line with American practice, with the difference, however, that non-skid chains are never used by French motorists. Michelin reports that his production of steel studded tires is 60 per cent less than before the war. Pirelli declares that he is now selling 40 per cent fewer steel studded tires than was the case two years ago. At the French factory of the Goodrich Tire Co. the production of steel studded tires, which represented 25 per cent of the total output, has been stopped altogether, owing to lack of demand.

Several causes seem to have contributed toward this rapid abandonment of the steel studded pneumatic tire. The American Army in France set an example of running its automobiles on all-rubber tread tires, which seems to have impressed French motorists. In addition, large stocks of these tires were left behind by the army and were sold when other types were almost impossible to obtain, thus initiating motorists to their use and giving them confidence in running on rubber treads.

Michelin Brings Out Cord

Michelin is also largely responsible for the change, for since the armistice he has brought out and featured a cord tire which of course has an all-rubber tread. As Michelin has by far the biggest output in France and equips at least 60 per cent of new French cars with tires his adoption of cord construction and rubber treads had an important influence.

The Goodrich company, which also has put a cord tire on the market, considers that the steel studded tread was often used because of the protection it afforded against punctures, and now that the same protection is afforded by cord construction, with longer life and lower cost, there is less reason for the use of the steel studded band. A contributory cause, it is pointed out, is the high cost

Indiana Road Work Waits Lower Prices

Policy of Prohibiting Necessary Construction Rouses Opposition of Industry

INDIANAPOLIS, May 27—Last week Governor McCray announced simultaneously the names to complete the reorganization of the State highway commission and a new policy of the commission—not to permit construction of highways in Indiana "until prices come down."

Organized units of the automotive industry are preparing for a session with the State highway commission. The automotive organizations hold that the commission policy should not prohibit improvement where necessary for improvement of traffic conditions.

Apparently the whole political framework of the present administration which took office Jan. 1 is directed toward suspension of highway extension. The State tax board, which has authority over highway and other bond issues, announced a few days ago "that the taxpayers have an opportunity of preventing unnecessary expense" by appealing to the tax commissioners. The last legislature passed an administration measure providing that where bonds carry more than 5 per cent interest and amount to more than $5000, the whole question must be referred to the State tax commission. Two road bond issues, one from Bush County and one from Marshall County, for permanent improvement of dirt roads were disapproved by the tax commissioners last week, killing both projects. Such a settled highway policy is arousing the automotive industry of the State.

Pershing an Advocate of Highway Commission

WASHINGTON, May 28—Another method of financing highway construction throughout the country has been advocated by E. J. Adams, former member of Oregon State Highway Commission and now Secretary to Senator Stanford of Oregon, when he appeared before the Senate Committee on Postoffices and Postroads in support of the proposed Townsend bill. He suggested that Congress authorize the issuance of bonds without interest which will also be legal tender for domestic obligations. He contended that this method would provide a market for bonds because Congress could authorize receipt for bonds on deposit, making them serial bonds payable over a period of years.

In support of his plans, he asserted that state highways and county roadways built nearly all after the issuance of bonds. These bonds must have a market, he said, and the market is so congested at present that they cannot be sold. The Committee appeared quite interested in his plan and questioned him as to the costs of highways. He estimated that it would cost $15,000,000,000 to build essential highways without consideration of maintenance costs.

General Pershing appeared on the stand today and advocated a central body, such as proposed in the Townsend bill, to direct Federal expenditures for road purposes. The General discussed highway legislation only in a general way. He stated that all roads were valuable and it was necessary at all times to get farm products to shipping points as well as to the army.

Representatives of the Federal Highway Council, organized farmers and others interested in highways appeared before the Committee this week. Senator Townsend expects to conclude the testimony by June and report the bill out for consideration at the special session.

N. A. C. C. to Distribute 500 Prizes for Essays

NEW YORK, June 1—Five hundred prizes for the best essays on safety are offered to the grammar school pupils of the United States by the National Automobile Chamber of Commerce. The contest is under the direction of the Highway and Highway Transport Education Committee, a group of men from United States Government departments and other associations interested in motor transport and highways.

The essays are to be written in the fall term so that children may have ample opportunity for observation and study of traffic dangers during the vacation months. Teachers in every municipality in the country will have full details concerning the contest at the opening of the 1921-22 term which they will be asked to detail to the children.

A trip to Washington, D. C., and a gold watch will be first prize. The second national prize will be a gold loving cup, and the third, a silver loving cup. In addition to these, medals and cash prices will be distributed in all states, territories and possessions of the United States. The Highway and Highway Transport Education Committee directing the contest is headed by the United States Commissioner of Education and includes experts on highway work.

FARMERS DISCUSS UNIT BUYING

INDIANAPOLIS, May 31—Co-operative buying and pooling of motor equipment were two subjects discussed by the purchasing agents of farmers' associations of Indiana and neighboring States, who met here Tuesday and today. O. J. Stierwalt of the Ohio Farmers' Commercial Service and W. H. Wagenbreth of the Missouri Farm Bureau were the principal speakers. Some of the "doctrines" advocated by these speakers would make the purchasing bureaus of farmer organizations huge distributing centers for vehicles, implements, etc. It was plainly intimated that one large manufacturer would readily make contracts with the farm bureaus, allowing substantial discounts for exclusive markets.

Oregon Gets Results in Highway Program

Co-operation of Counties Links State With Main Routes on Coast

PORTLAND, ORE., May 31—The thirty-five counties of the State of Oregon have bonded themselves to the extent of $15,363,704 for road improvement since the advent of the automobile, practically all of the money being voted within the last three years, and considerably more than half of it still remaining unspent, according to a summary made public this week by the State Highway Commission. This is in addition to the State road money and the Federal aid money which has been provided along with county funds.

Under the Oregon system the State Highway Department stands ready to aid the various counties by putting up half the cost for improvement of the main highways. This liberal program has resulted in activity in the various counties, both in meeting the State funds for improvement of main highways and for secondary roads connecting with the main highways.

While no summary is made, it is estimated that at least half of the money obtained from county bond issues, which has been spent thus far, has gone, together with State funds, into improvement of three important roads, the Pacific highway, running north and south, and connecting with California; the Columbia River highway, the great east and west road, and the Old Oregon Trail, which connects with the Lincoln highway from the east.

Oregon is to have a second main highway into California, according to action of the State Highway Department this week in permanently establishing the location for The Dalles-California highway. The highway, which has been recognized for some time as one of the important State roads, but had not been located with a view to permanent improvement, begins at The Dalles, on the Columbia River, and runs southward through central Oregon into California. The road will be an inland route as compared with the Pacific highway, which is a coast route. Near the Oregon-California line the new highway will swing westward, joining the Pacific highway in northern California and affording an immense loop for travelers from Portland to California and return.

Locate First of New System

Location of the first 100 miles of this road, from The Dalles south, was made by the highway commission last week, and it is estimated that $1,500,000 will be required to grade the road and surface it with gravel. Work will start in 1922 and it will take several years to complete the road. In the meantime the present roads, which are narrow and have some severe grades, will be used by those desiring to make the trip to California by the eastern route.

W. R. Wilson Named Maxwell President

New Executive Was Formerly with Dodge and Studebaker—Takes Office June 15

NEW YORK, June 2—The election of William Robert Wilson as president of the Maxwell Motor Corp. was announced here to-day by Walter P. Chrysler following a meeting of the Maxwell board of directors and the reorganization committee of the company. Wilson has been a vice-president of the Irving National Bank and will sever this connection at once to assume his duties with Maxwell on June 15.

In announcing Wilson's election, Chrysler said, "I consider Mr. Wilson one of the strongest executives in the automobile business."

Wilson's introduction into the field of automobile manufacturing was with Studebaker, where he began as assistant to the manufacturing manager and rose to assistant to the general manager. On Dec. 1, 1913, he went with Dodge Brothers, where he remained five years, and then resigned to accept the vice-presidency of the Irving Bank.

In his connection with the Dodge brothers he was directly associated in the organization of their motor car business. He was credited with considerable of the responsibility for the selection of their organization and the upbuilding of their departments, whether pertaining to manufacturing, distribution or commercial phases of the work.

When he takes office Wilson will be one of the youngest executives in the industry. He is a graduate of the Armour Institute of Technology, where he received the M. E. degree in 1909.

Announcement was made by AUTOMOTIVE INDUSTRIES on Feb. 15 that the selection of Wilson was being considered by Chrysler and the reorganization committee. It was deemed advisable, however, to defer the formal announcement until transfer of the Maxwell and Chalmers properties to the new company was well under way.

Directors of Company Elected

Directors of the company elected were Walter P. Chrysler, chairman of the board; Fred T. Murphy, J. R. Harbeck, James C. Brady, C. C. Jenks, Harry Bronner, William Robert Wilson, Elton Parks, J. S. Bache, E. R. Tinker, Henry Sanderson, Carll Tucker, Allen F. Edwards, Thomas F. Dougherty and T. C. P. Martin.

Officers elected in addition to President Wilson are W. Ledyard Mitchell, Carll Tucker and A. B. Barker, vice-presidents; T. H. Thomas, controller, and Jackson B. Clark, E. W. Clark, L. W. Linaweaver and Horace Davies, assistant secretaries.

The executive committee of the company is Walter P. Chrysler, Elton Parks, Fred T. Murphy, Allen F. Edwards, Harry Bronner and C. C. Jenks.

Dealers Flood Congress with Dumping Protests

WASHINGTON, June 1—Automobile dealers throughout the country are flooding Congress with protests against the reimportation of American-made trucks. The movement is not confined to the Atlantic and Pacific seaboards where sales have been heaviest, but has extended to small communities in the Middle West. For instance, the Motor Trade Association of Riley County, Kansas, adopted a resolution urging Congress to enact legislation to prevent dumping of salvaged material from European war areas in competition with American industry. All of these protests have been filed with the Senate Committee on Finance.

The protests are rather late to bring effective action, for the anti-dumping bill has passed Congress and has been signed by the President. It was understood that its provisions might offer some relief from the reimportation menace, but persons who have studied it carefully contend that before a tax can be imposed on the difference between the exporter's sale price and the foreign market value, price discrimination against this country must be shown. It might be possible for a customs appraiser to hold up a shipment pending investigation, but as it stands now there is little prospect for real relief under the existing law.

Miller Encourages Loans on Car Paper

(*Continued from page* 1176)

ally toward borrowers, as against their attitude a year ago. Bankers are far more conservative now; they are improving their position and have plenty of excuses of their own for declining a loan, without having to fall back on the old excuse that the Federal Reserve Bank will not rediscount the paper.

Further, the motor car dealers and distributors are, it is said, in no frame of mind to take on obligations, and stocks with cars and accessories. It seems perfectly safe to offer large credit facilities, since only a small part of the facilities are likely to be asked for.

The manufacturers may want this credit, to assist toward larger production—but so far as possible the Kansas City financial resources will be conserved to care for the distributors of this district, to be available for them after factory production has prepared the supply for them.

Altogether, the announcement of Governor Miller regarding rediscounting of automotive paper, is the keynote in the portrayal of improving conditions.

FRED W. MORGAN DIES

CHICAGO, May 27—Fred W. Morgan, founder of the firm of Morgan & Wright, bicycle tire manufacturers, died at his home here yesterday of angina pectoris. Mr. Morgan was born in New York, March 30, 1854.

Seiberling Buys Newcastle Rubber

Secretary Acts as Representative —Sale Price $103,000—Held Controlling Interest

AKRON, May 28—The Newcastle Rubber Co. at New Castle, Pa., was purchased at receiver's sale yesterday by R. C. Ellsworth of Akron, who served as private secretary to former President F. A. Seiberling of the Goodyear company. Ellsworth, it is reported, bid in the plant as representative of Seiberling. Seiberling attended the sale. The plant is valued at over $500,000. The sale price was $103,500.

F. A. Seiberling is reported to have held a controlling interest in the Newcastle Rubber Co. for some time, having originally purchased the plant more than a year ago for one of his sons who since has been forced to go West for his health. Through Seiberling's financial difficulties at Goodyear, the Newcastle plant became involved and was placed in the hands of trustees. Seiberling reported that the purchase of the plant through Ellsworth does not mean that he will again become actively engaged in the rubber industry, for it is known that he has other definite plans in process of development at this time. The Newcastle plant includes two large and fully equipped factory buildings, seven and one-half acres of ground, an office building and three dwellings.

Americans Sweep Indianapolis Race

(*Continued from page* 1176)

dangerous possibilities but both escaped as well as their mechanics.

Broken water connections on the Talbot, Sunbeam and one of the Frontenacs accounted for the elimination of these cars. Where these broken connections were located technical committee reports do not make clear. Probably water pump trouble accounted for most of them.

A rather peculiar condition accounted for the elimination of Pete Henderson's Junior Special. Freezing brakes caused the wheels to skid and resulted in the car swinging into the side wall.

Joe Boyer's Duesenberg had to be pushed into the pits and withdrawn after he had driven a very pretty race and in fact had pushed De Palma very hard during the first few laps, winning the sixth. His trouble was a broken axle shaft.

A consistent race was driven by the winner. He stopped on the 77th lap for two front tires and again was flagged by his pits to come in for gas and oil on the 160th lap.

A great amount of interest was created in the Frontenac driven by Tom Alley. This was fitted with Disteel wheels and was able to carry for this reason 10 lb. additional air pressure in the tires. This car ran well, being for a large part of the race in third place and gaining on the leaders.

Many Price Reductions Announced

Quick Price Action Urged by N. A. D. A.

Stability of Market for Cars Threatened by Indecision, Declare Dealers

ST. LOUIS, May 31—In an effort to end the present unsettled condition in sales, due to continued drops in price, General Manager Harry G. Moock of the National Automobile Dealers' Association to-night wired all manufacturers of motor cars, asking them to make any contemplated reductions at once.

The appeal was prompted by a flood of letters and telegrams from dealers all over the country, urging the N. A. D. A. to do anything within its power to bring the present condition to an end. Reports from all sections state that each successive price reduction puts an additional damper on general buying of cars and indications are that if the reductions are spread over the summer the season's business will be ruined. Leading dealers, however, feel that there can be a good business this summer if the price question can be disposed of at once.

General Counsel C. A. Vane of the N. A. D. A. conferred this week in New York with General Manager Alfred Reeves of the N. A. C. C., which conference developed that the manufacturers as an organization do not care to discuss prices. With legal opinion closing this avenue of appeal the only remaining course was a request by the N. A. D. A. to each car maker individually. The telegram follows:

"Dealers all over the United States have been wiring here, asking National Automobile Dealers' Association to lend its help to stabilize the present price situation. They complain the public is refusing to buy any merchandise because of uncertainty of future prices of automobiles. May we on their behalf ask you to announce immediately whether your factory will make price reduction or adhere to present prices for a definite period. The question is not so much one of price as of stabilization. For that reason we believe an immediate declaration should be made by each manufacturer as to what his policy is going to be if we are going to reestablish a buying market."

Federal and Oldsmobile to Hold Present Prices

DETROIT, May 28—Federal Motor Truck Co. sent out a letter this week guaranteeing prices on Federal trucks to Oct. 1. The notice which was sent out by W. C. Rowley says while there has been some slight reduction in the price of steel recently, the cost of manufacture has not been affected thereby.

Olds Motor Works also has notified distributors that there will be no price reduction in the Oldsmobile line. The letter points to the introduction last December of the new four-cylinder model and says the factory could not have produced this car at this time were it not for the fact prices had been predicated on a later drop in the price of material and labor and a certainty of volume production.

Lafayette Prices Cut Ranging $750 to $950

INDIANAPOLIS, June 1—Price reductions ranging from $750 to $950, effective to-day, are announced by the Lafayette Motors Co. Prices are f.o.b. Indianapolis, including standard equipment. The new prices are: Touring car $4,850, reduced $775; roadster $4,850, reduced $775; four-door coupe $6,250, reduced $950; sedan $6,500, reduced $900; limousine $6,750, reduced $750.

LINCOLN DOWN $300 TO $800

DETROIT, June 1—Price reductions have been made effective to-day by the Lincoln Motor Co. The new prices are: Open models $4,300, reduced $300; coupe $4,950, reduced $800; sedan $5,400, reduced $600; limousine and town car $6,000, reduced $600.

HAYNES GUARANTEES TO 1922

KOKOMO, IND., June 1—Prices on Haynes cars will be guaranteed to Jan. 1, 1922, it has been officially announced by Alton G. Seiberling, president of the Haynes Automobile Co. "Our present margin of profit is so slight," he declared, "that it would be impossible for us to reduce prices."

HANDLEY GUARANTEES PRICES

KALAMAZOO, MICH., June 1—The Handley-Knight Co. has notified its distributers that their prices are guaranteed up to Jan. 1 next. The statement says the lowest prices possible to be maintained were fixed last November and were $500 less than were justified by conditions at that time.

RECEIVER TO SELL BODY PLANT

DETROIT, June 1—The property of the Detroit Weatherproof Body Corp. at Corunna, Mich., will be sold at public auction June 17 by the Security Trust Co. of this city as receiver.

HUDSON-ESSEX DOWN $150

DETROIT, June 2—Price cuts of $150, effective to-day, are announced on all models of Hudson and Essex cars.

Nash on Half Time as Sales Fall Off

Production Cut to 65 Daily Pending Developments—Price Cuts Harmful

KENOSHA, WIS., May 28—Following reduction of working schedules by the Nash Motors Co. of Kenosha, Wis., to a basis of a full half-day six days a week, due to over production, certain departments have been shut down temporarily pending improvement in the demand for cars. A statement by President Charles W. Nash says in part:

"Automobiles take up when finished an unusual amount of storage space, and the operation of an automobile factory, insofar as the completed car is concerned, is controlled almost entirely by the demand for the product. In other words, if orders suddenly cease to come in, we can run but a short space of time due to the fact that we have not the storage room. It means a severe loss to shut down a plant and allow the organization to scatter, and if for no other reason than this we do our best to run continuously.

"We decided last week that it would be better to operate a full half-day each day and make 65 cars in the half-day than it would be to try to carry this over a full day's work, due to the fact that it would be necessary to have reduced our working force materially if we attempted to operate all day; whereas if we operate a half-day we are able to keep a great many more employed.

"We have no definite date fixed when we may be compelled to close down for a short while entirely. This will be due to the condition of the business throughout the country. Our dealer body had a considerable number of cars on hand, and the extreme cold, backward weather that we have been having all spring is not conducive to selling automobiles.

"Another thing: Some companies have been able to reduce their prices materially, and this has upset in a measure the prospective buyers of Nash cars. My judgment is that if we should get some settled, warm weather, selling would take a new lease on life and business would go on to a considerable extent. However, it is impossible to tell exactly what the attitude of the public is going to be."

SHERIDAN PRICES DOWN

MUNCIE, IND., June 1—The Sheridan Motor Car Co., which went into the control of W. C. Durant last week, has cut its prices. The roadster and touring car now sell at $1485, a cut of $200; the coupé at $2265, a cut of $300, and the sedan at $2765, a cut of $300.

Cars in All Price Classes Are Cut

Studebaker Prices Down $150 to $200

Light Roadster Added to Line to Sell at $1300—Twelve Cars Reduced

NEW YORK, June 1—Price revisions covering its entire line and ranging from $150 to $200 were made by the Studebaker Corp. to-day, the new prices to take effect at once. In making the price cuts the company announces a new EJ-40 model roadster to sell at $1,300. The new and former prices follow:

	New Price	Former Price
Model EJ-40		
Roadster	$1300	New model
Special body roadster	1695	$1850
5-passenger	1335	1485
Sedan	1995	2150
Model EH-50		
Roadster	1585	1750
5-passenger	1635	1750
4-passenger	1635	1750
Coupe	2450	2650
Sedan	2550	2750
Model EG-60		
7-passenger	1985	2150
Coupe	2850	3050
Sedan	2950	3150

President Erskine of the Studebaker Corp. has announced that April sales numbered 6589 cars, as compared with 2602 of April, 1920, while May sales were 7400 against 4024 for the same month last year. Unfilled orders approximate 7000 cars. May collections exceeded $12,000,000. Profits for this quarter are expected to exceed $5,000,000 before taxes.

CHALMERS PRICES DROP

DETROIT, May 27—The following price reduction was announced by General Sales Manager A. E. Barker on Chalmers cars: 5-passenger touring, from $1,795 to $1,545; roadster, $1,795 to $1,495; 7-passenger touring, $1,945 to $1,795; 5-passenger sport, $1,995 to $1,695; coupé, $2,595 to $2,295; sedan, $2,745 to $2,445. All prices f.o.b. Detroit.

CHEVROLET CUTS ITS "FB" LINE

NEW YORK, June 1—Following its recent action in reducing the prices on its "490" line, the Chevrolet Motor Co. has cut the prices of its "FB" line. The touring car has been reduced to $1,185 from $1,345, the roadster to $1,185 from $1,320, and the sedan and coupe to $1,885 from $2,075. The prices are f.o.b. Flint.

KING TO BUIILD NEW COUPE

DETROIT, May 31—King Motor Car Co. will put a new King 8 coupe on the market with deliveries about August 1. Announcement of the new member of the King family was made by President Weber in a letter to the trade this week. The only reference to price is the statement in the letter that above everything else in the automobile to-day it must be built to meet "to-day's pocketbook."

Buick Cuts Prices Ranging $300-$660

FLINT, June 1—Price reductions on the Buick ranging from $300 to $660 went into effect to-day. Simultaneously with the reductions the Buick line assumes the serial number "1922" instead of "1921" which expired May 31. It was announced that present models will be carried through the 1922 season.

Old and new prices are as follows:

		Old Price	New Price
1922-44	Roadster	$1795	$1495
1922-45	5-passenger	1795	1525
1922-46	3-passenger	2585	2135
1922-47	5-pass. Sedan	2895	2435
1922-48	4-pass. Coupe	2985	2325
1922-49	7-pass. Touring	2065	1735
1922-50	7-pass. Sedan	3295	2635

Buick guaranteed prices to the public to May and to dealers to July 1 on the 1921 models. The guarantees are not applicable to cars bearing the 1922 serial numbers.

SENECA REDUCES PRICES

FOSTORIA, OHIO, June 2—The Seneca Motor Car Co. has reduced the prices of its two and five passenger touring cars from $1185 to $1045 and of its truck from $1160 to $1020.

TEMPLAR MAKES BIG CUT

CLEVELAND, June 2—Price reductions of $500 on open models and $600 on closed models, effective July 1, are announced by the Templar Motors Co. The two, four and five passenger touring cars have been reduced from $2885 to $2385 and the sedan and coupé from $3785 to $3185. Prices are f.o.b. Cleveland.

FRANK H. WHEELER DIES

INDIANAPOLIS, May 28—Frank H. Wheeler, 57 years old, Indianapolis millionaire, committed suicide yesterday morning by discharging the contents of both barrels of a shotgun into the left side of his head. Mr. Wheeler was one of the founders of the Indianapolis Speedway, president of the Wheeler-Schebler Carburetor Co., and was connected with the Stutz Fire Engine Co., being vice-president, and was president of the Wheeler-Langsenkamp Brass Co. It is believed his action was due to despondency over the condition of his health and also brooding over the death of Seymour Avery, an associate.

Franklin Makes New Revision in Prices

New List Approximates Scale Fixed in September Reductions of 1920

SYRACUSE, June 1—Franklin announced to-day price reductions on open cars ranging from $150 to $200 and on inclosed cars from $200 to $250, effective immediately. The reductions follow a small increase on the Franklin line made March 1, which in turn had been preceded by an increase of $100 Jan. 1 coincident with the appearance of the new hood.

The present reductions bring Franklin prices within $50 to $150 of the low level of September, 1920, when Franklin, following close on the heels of Ford, was the second manufacturer to announce a substantial post-war price cut. Franklin prices are now $400 to $750 below the high war-time levels.

A comparative summary of Franklin prices follows:

	New Price	March 1921	Sept. 1920	High war-time
Touring	$2,650	$2,800	$2,600	$3,100
Runabout	2,550	2,700	2,400	3,050
Roadster	2,550	2,750	2,500	3,100
Sedan	3,650	3,850	3,600	4,350
Brougham	3,550	3,800	3,500	4,300
Demi-coupe	2,850	2,950	2,750	3,300
Demi-sedan	3,050	3,150	(New Type)	(New Type)
Chassis	2,225	2,300	2,225	2,625

"Wages are not being cut," H. H. Franklin declared. "With our price cut last fall sales started on the upgrade, and from month to month during the early winter season held very near to factory capacity. Since December we have not had on hand at the factory on any one day more than three days' production of cars, and right now our dealers' stocks are lowest of the year.

"Reduction in the price of Franklin cars is being made without any reduction in wages. We hope that the new basis will permit the continuation of the present working force, without the contractions that are usually expected in the automobile industry in the midsummer months. Our previous price adjustment also left wages unaffected and was accompanied by a slight increase in employment."

ELGIN PRICES REDUCED

ARGO, ILL., June 1—The Elgin Motor Car Corp. announces price reductions ranging from $180 to $300, effective tomorrow. The price of the touring car has been cut from $1775 to $1595; the sedan and coupé from $2795 to $2495.

Death of Batchelder Shock to Motordom

First Became Roads Enthusiast in Bicycle Days—Tragedy Ends Noted Career

NEW YORK, June 1—A pall of grief has been cast over the entire industry by the tragic death of Amos G. Batchelder in the airplane disaster near Morgantown, Md., which cost seven lives. The universal esteem in which he was held was evidenced at his funeral to-day.

Every branch of the automobile industry in this country and abroad had representatives at the funeral. Floral tributes were received from the National Automobile Dealers Association, Motor Union of Great Britain, and from every automobile and aero club in this country and Canada. Representatives of these organizations and the Department of the Interior, Bureau of Public Roads, Chamber of Commerce of the United States, Brigadier General Mitchell of the U. S. Air Service, National Geographic Society, Aero Club of America and five past presidents of the A. A. A. were present.

Services were conducted by Rev. Ulysses G. B. Pierce, rector of All Souls Unitarian Church. Among the floral offerings was an attractive piece from the Oldtimers, an organization of automobile pioneers. Batchelder became associated with this organization during his five years' service as an editor for the Class Journal Co. He has been executive chairman of the A. A. A. for eleven consecutive years and was re-elected recently for a term of four years.

The body was taken to Buffalo where it will remain in a vault until fall and then be interred in the family plot at Attica, N. Y.

Hundreds of messages of condolence have been received by Mrs. Batchelder, who was visiting relatives in Jackson, Mich., when she received word of her husband's death.

Popular in Washington

Probably no man in the history of the automobile has been better loved than Batchelder and few have done more than he for the motor vehicle. As executive chairman of the American Automobile Association he was known personally to thousands of motorists in every section of the country, and they were fully appreciative of his ceaseless efforts to promote better highways. In no circle, however, was Batchelder more popular than in official Washington. He had stood high in the esteem of several administrations and his views on highways always commanded respect.

Back in the days of the bicycle, when most people looked upon any proposal to build roads as only another means of burdening them with taxes, Batchelder foresaw their need and their value, and he was first to recognize the importance of bringing the Federal government into highway building. When President Wilson signed the Federal Aid Road Act on July 11, 1916, thereby bringing the Government into road building after more than 75 years of a passive attitude toward highways, Batchelder all but collapsed. He had reached the goal of many years of effort and did not realize until then his weariness from the strain he had been under.

Batchelder had very clear and definite ideas on highway legislation and road building, and he lived to see his ideas generally accepted. He talked good roads incessantly, in season and out, to everyone he met, because he believed everyone should share his enthusiasm and that by incessantly talking good roads he would win more good roads advocates. He had traveled many thousands of miles into every part of the United States to speak on his favorite topic. He was to have delivered addresses on this theme in Salt Lake City, June 16 and 17. He had been one of the foremost advocates of the Townsend bill.

Never Too Tired to Boost

In spite of numberless obstacles, Batchelder never became discouraged. He never was too ill or too tired to travel to any point of the United States where he might be needed to bolster up a slipping bond issue for highway building. To him more than to any other one man the motorists of the United States owe a debt of gratitude for the charting, sign marking and improvement of the roads they use.

While promotion of highway legislation, building and maintenance always has been a large part of the work of the A. A. A., Batchelder gave generously of his own time and money to the cause in the serene belief that his work in this direction was a service to the country.

(Continued on page 1190)

BATCHELDER A POWER IN CAR DEVELOPMENT

NEW YORK, June 1—This tribute is paid to A. G. Batchelder by James Rood Doolittle in his "Romance of the Automobile Industry":

"A. G. Batchelder, chairman of the executive committee, is the commander in the field of all the armies of Three A's. He presides at the councils and for years has had more influence with the various administrations than anyone else. He edits and manages The American Motorist and, ex-officio, has a hand in nearly every activity of the organization. Mr. Batchelder was a newspaperman of prominence before entering the automobile field, and during the past ten years has developed qualities of much importance to motordom. As an executive he is conservative; as a diplomat, effective, and as a motorist, radical."

Ford Helps Detroit Show Gain in May

Increases Output 20,000 While Most Others Fall Off—Reduce Working Forces

DETROIT, June 1—Automobile production in Detroit and the State of Michigan for May totaled 144,601, as compared with 140,955 in April and 142,083 for May last year. The increase over last month was largely due to the Ford output of 101,897 cars and trucks. The April total without Ford was 50,830 and for May, 1920, without Ford was 62,085.

Decreases compared with April were shown by all factories save Ford, Buick, Hudson-Essex, Lincoln, Oakland and Packard. All factories are working short forces but full time in most instances. Dodge was down three days last week, but officials say the plant will be operated full time hereafter in spite of persistent reports that the three-day schedule would continue.

Ford announces that orders ahead of production total more than 100,000 in spite of an output of more than 90,000 in April and more than 100,000 in May. Reports that production had been cut 1000 daily were denied, and it was asserted that no such decrease was in contemplation. Ford officials said it was natural to expect a downward trend to begin late in June, but that everything now points to increasing demand.

Manufacturers See Need for Decision on Prices

NEW YORK, June 2—That every means possible should be taken to stabilize the industry, especially on the question of prices, was the general opinion of manufacturers who attended the annual meeting of the National Automobile Chamber of Commerce here today. It was felt that whatever reductions are contemplated in prices should be made at once in fairness to dealers and to the purchasing public.

W. P. G. Harding, governor of the Federal Reserve Board, addressed the members of the N. A. C. C. at noon to-day. He reiterated that there would be no discrimination against automobile paper, even in the Kansas City district, and declared that so far as finances are concerned he can see no reason for anything but optimism for the future.

The members will listen this afternoon to a debate on the problem of unit parts service, to reports on business conditions in all sections of the country and there will be a discussion of the motor truck reimportation question.

It is probable the retiring directors will be re-elected and that at the organization meeting the directors will re-elect Colonel Charles Clifton as president.

The special committee headed by J. Walter Drake which will co-operate with Secretary of Commerce Hoover, will meet with Hoover to-morrow.

Fiat Plant Reopens on Six Hour Basis

Company Successful in Imposing Work Conditions—Stinnes Not Controlling Company

TURIN, ITALY, May 20 (By Mail)—After a lock out lasting 32 days, the Fiat factory has reopened on the conditions imposed by the owners. The works are now running on a 6-hour basis, working 6 days a week. The dispute arose over the claim of the men that they should have a control in shop management and the right to decide when men should be laid off. Rather than accept this the management closed the entire factory, throwing 12,000 hands out of work, and put troops in possession of the entire establishment.

When 8000 men had signed an agreement to accept the disciplinary measure imposed by the directors, and to execute any kind of orders, whether for peace or war, it was decided to open the factory. The general elections which have just taken place completed the downfall of the socialist and communist movement, for the ringleaders who were responsible for the revolutionary outbreak last September failed to secure a majority.

Local trade is in a very depressed condition, with the result that the smaller companies, having few foreign connections, are badly hit. The bigger firms, such as Fiat, Lancia and Isotta-Fraschini, are kept busy on foreign orders. The recent automobile taxes, under which a 35 hp. car pays $3,000 a year at nominal exchange, is having its effect on the industry, and some firms having specialized on big cars up to the present are preparing to produce engines of lower power for next season.

Fiat has opened an automobile factory in Warsaw, Poland, the concern being registered under Polish laws and having a capital of five million Polish marks. Half this capital has been subscribed by Polish financiers and half by Italian interests. Cars and trucks are being produced under the technical direction of the Italian Fiat Co. Business prospects are declared to be good.

The report that Hugo Stinnes had obtained control of the Fiat Automobile Co. is officially denied by that concern, which declares that the German iron king does not hold any stock or have any connections with the leading Italian automobile company. The report seems to have got abroad when Stinnes purchased 20,000 shares in the Alpine Montan Gesselschaft, in which Fiat directors were also holders. The two concerns, however, are entirely distinct.

DIESEL AGENTS NAMED

CHICAGO, May 31—The Dalton-Elliott interests, Wrigley Building, this city, have contracted for the exclusive representation of the Export Gesellschaft fur Deutsche Fabrikate for the North American continent. This carries with it exclusive sales and purchasing representation. The organization is composed of 54 manufacturers in Germany representing practically all lines of industry. It controls a large portion of dye production and, among other products, the Diesel engine. The contract calls for the purchase of raw materials in this country.

Cars Take Second Place in Leading Industries

WASHINGTON, May 31—Automobiles ranked second in the value of products produced in 1919, according to a preliminary statement of the 1920 census of manufacturers, issued to-day. With 315 establishments reporting in 1919, the estimated value of automobiles was $2,387,833,000. This figure is supplemented by 2394 establishments producing automobile bodies and parts to the value of $673,593,000 and 15,486 establishments listed as automobile repairing with production valued at $222,596,000.

The meat packing industry led in the value of products.

These comparative figures illustrate the growth of all branches of the industry, for in 1914 there were only 971 establishments producing automobile bodies and parts with a total production of 129,601,000 and in the same year 3273 automobile repair establishments reported production valued at $29,920,000. Thirty-one establishments manufacturing airplanes, seaplanes, airships and parts in 1919 with a value of $14,373,000 as against 16 establishments in 1914 with production valued at $790,000.

FIRST DUESENBERGS BUILT

INDIANAPOLIS, May 28—The Duesenberg Automobile Co. placed on display in the plant yesterday a roadster, a chassis and a touring car, the first automobiles to be manufactured for sale by the local company, which marks the beginning of production in the first of the three units of the company. The first shipment of automobiles to agents will be made July 1. The six cars entered in the Speedway race were manufactured here, and finishing touches are being put on four racing cars to be entered in the Grand Prix race at LeMans, France, July 26.

TO SELL IMMEL PLANTS

COLUMBUS, May 31—Upon the application of Robert H. Schryver, receiver for the Immel Co., the court ordered the sale of the plant and other assets. The south plant is to be sold for $200,000; the plants on Livingston Avenue for $20,000 and $17,500, and the land at $1200 per acre. All material on hand is to be sold for cash. The preferred stockholders have perfected plans to make a substantial bid for the properties and has made arrangements with J. D. Potter, formerly vice-president of the Kilbourne & Jacobs Co., to head the organization if they secure the plants.

METAL MARKETS

WITH the normally dull period in the steel market ushered in the theme that is in the foreground of discussion is whether there will be a revival of demand in August. In past years when the steel industry suffered from extreme stagnation in the last half of the second and the beginning of the third quarter, it was always August that brought the turn. Optimists among the producers aver that by July the steel market will have reached so moribund a condition that August is certain to bring a reaction. The pessimists say that if the revival does not come in August they will abandon all hope for better conditions during the remainder of the year. Aside from the leading builder of low-priced passenger cars who continues to figure more or less in all departments of the steel market, buying for automotive account is of retail proportions and on the hand-to-mouth order. What little in the way of orders is being placed goes to those mills that have been able to maintain operations on a one-third capacity basis. The reason for this is that those mills which are in operation can make shipments within a few days, while those that are down are prevented from resuming operations until they are fortunate enough to accumulate a sufficient backlog of orders. Prices are extremely soft, and in all transactions that are even remotely representative concessions are the order of the day. Reluctance to shade the nominal quotations is confined to those producers who are not operating anyway. Those who are striving with might and main to keep at least a third of their plants going are more than ready to offer inducements whenever tonnagers and specifications are in the least attractive. The strip steel market reveals sharp cuts by individual mills apparently in an effort to determine whether these concessions will bring out any business. All of the automotive buying of sheets is for instant shipment, and most sheet mills do not know from one day to the next whether they will have enough orders on the morrow to warrant a continuance of operations.

Pig Iron.—Although production continues at famine proportions and the market, if its statistical position governed, should be more than strong, prices are pliable. Even at $23 automotive foundries seem to show little interest. All of the iron for the Ford Motor Co.'s castings is being supplied by its own furnace.

Steel.—New demand for steel bars is light and Chicago bar mills face the end of their backlog of orders...Forging quality bars are being shipped to the Ford Motor Co. by Ohio valley mills that are reported to have taken the business at concessions of $3 per ton. Cold-rolled strip steel is offered in Pittsburgh at 5c. and hot-rolled at 2.55c., compared with 5.50c. and 2.75c., respectively, supposed to be leading producers' quotation. Bolt and nut buying has died down.

Aluminum.—The market continues flat and quotably unaltered.

Copper.—A new copper contract became effective on the New York Metal Exchange June 1. It permits trading in Standard copper, by which term anything running from 96 per cent upward in purity is known. The new contract is designed on the pattern of that in vogue in London and intended to "broaden trading" in copper. If this object is attained, it will mean "outside" speculation which, at times, may bring about artifical conditions that call for extraordinary caution on the part of consuming buyers.

FINANCIAL NOTES

Fisher Body Ohio Co. paid a $2 dividend on the preferred stock May 31. This is the April 1, 1921, dividend, which was suspended until it was determined whether the common stockholders would accept or reject the share exchange offer made by the parent company. The plan was declared operative May 10.

Commonwealth Finance Corp. has declared an extra dividend of one-half of 1 per cent in addition to a quarterly dividend of 1 per cent on its common stock; also a semi-annual dividend of $3.50 a share on its preferred stock, all payable July 15 to holders of record June 30.

Pierce-Arrow Motor Car Co. directors have voted to pass the quarterly dividend on preferred stock due July 1, to conserve the assets of the company during the present period. Quarterly payments of 2 per cent have been made on this issue since Jan. 1, 1917.

Rolls-Royce, Ltd., in a balance sheet for the year ended Oct. 31, 1920, shows net profits of 202,835 pounds sterling, which compares with 192,777 pound for the previous year.

Winfield Barnes Co., Philadelphia, will be sold at receiver's sale, permission for which has been granted by Judge Thompson in United States District Court.

Milwaukee Rolling Mill Co. will increase its capitalization from $1,500,000 to $3,000,000, to provide for expansion.

Auto Car Co. has declared a regular dividend of 1½ per cent payable June 10.

INDUSTRIAL NOTES

C. H. Wheeler Mfg. Co., Philadelphia, manufacturers of pumps, condensers, etc., has opened a new branch office in Boston at 53 State Street.

Stutz Motor Car Co. has started rebuilding the units of the plant destroyed in the recent fire. Production has not been hampered seriously.

Los Angeles Trailer Co., Los Angeles, has changed its name to the Utility Trailer Mfg. Co., with no change in personnel or location.

Marion Plants Find Business Outlook Good

MARION, IND., May 31—Automotive industries of Marion are in fair condition and the future outlook, according to information this week, is for a big increase in production in the next 60 days. Reutenber Motors Corp. is just getting settled into its new plant. It is not in operation. Orders on the books and inquiries that have been received in the last few weeks indicate much new business. The plant will be in operation this fall.

Velie Motors plant, formerly the Rutenber plant, is not in production on power units. It is occupied almost entirely with experimental and laboratory work and it is understood that when production is organized for this fall, a new design of power plant will be announced.

The Indiana truck plant is going steadily on a curtailed schedule. A steady income of orders from Mexico and the Central States is causing preparations for an increased production in June. Most of the new business is coming in from Chicago, Kansas and Texas and is a decided increase over April.

On 50 per cent production now, the Western Drop Forging Co. expects to be in full production on automotive parts within 30 days if business in that time continues as through the last month.

G.M.C. Denies Report of Fusion with Austin

NEW YORK, June 1—The General Motors Corp. denied to-day reports from London that it had been instrumental in arranging a loan for the Austin Motor Co. through W. P. Bonbright & Co. The London report was that there might be a virtual fusion of the British interests with those of General Motors.

Greater credence was given the report because the assistance for Austin came from an unexpected source. It was said at General Motors headquarters, however, that the corporation had no interest in the Austin company beyond a claim for a comparatively small sum for goods furnished. There were reports in London a year ago that Austin was anxious to have General Motors acquire an interest in its business.

Weideley and Midwest Extend Engine Schedules

INDIANAPOLIS, May 28—Officials of the Weideley Motors Co. are planning a production schedule of 14,000 engines for 1921, and in order to produce engines according to the schedule, approximately 4900 tons of raw materials are to be purchased. By the end of the year the company plans to employ about 750 men, or the maximum. An export business of 2 per cent of the output was done by the company last year. The company is selling its product to 22 companies at the present time. It will continue to specialize in engines for automobiles, but intends spending some effort in the development of its tractor department.

A production schedule of 18,000 engines is being planned by officials of the Midwest Engine Co., and it is also planning to get in on the ground floor in the export end of the business. Engines for fifteen concerns are being made by the company and they are planning to have 1800 men employed by Dec. 31.

TO MAKE CAR FOR COAST

LOS ANGELES, June 1—The West Coast Automobile Mfg. Co., organized to manufacture passenger cars, trucks, tractors and trailers in this city, will first bring out an automobile in six and eight-cylinder models, to be known as the Mission. The car will be of featured design and it is proposed to distribute it exclusively on the Pacific Coast. The design of the car above the frame is covered by patents held by Augustus W. King, first vice-president, general manager and designing engineer. The company is incorporated for $1,500,000.

BANK CREDITS

Written exclusively for AUTOMOBILE INDUSTRIES *by the Guaranty Trust Co., second largest bank in America.*

NEW YORK, June 2—The local money market again gave signs of firmness last week. Call money ranged from 6½ per cent to 7½ per cent, as against 6½ per cent to 7 per cent the previous week, with a ruling rate of 7 per cent, which was the renewal rate every day except Tuesday, when 6½ per cent was the renewal figure. On Thursday and Friday 7½ per cent, the highest quoted rate since Feb. 8, was reached during the trading periods. There was little activity in the time money market, where rates were also higher. Sixty and ninety days' and four months' paper were quoted at 6¾ per cent to 7 per cent, as against 6½ per cent to 6¾ per cent the previous week, while five and six months' paper were quoted at 6¼ per cent to 7 per cent, as against 6 per cent to 6½ per cent the previous week. Among the factors having a bearing on the firmer tone in the money market last week were the large Government withdrawals and the preparations for the first-of-the-month's disbursements. In addition, there were in the neighborhood of $150,000,000 in new issues during the week, of which the French 7½'s accounted for $100,000,000.

The Federal Reserve System continued to show the improvement which had been made consistently since the first of the year. The mid-week statement showed increased gold reserves of $14,041,000, and increased cash reserves of $9,098,000. Bills discounted secured by U. S. Government obligations increased $19,082,000, and total bills on hand $33,174,000. Total earning assets, however, declined $50,858,000, almost wholly as a result of decreased holdings of U. S. certificates of indebtedness. Total deposits declined $10,686,000 and Federal Reserve notes in circulation $32,611,000. As a result of these changes, the ratio of total reserves to deposit and Federal Reserve note liabilities combined increased from 56.8 per cent to 57.6.

Foreign Exchange Irregular

The foreign situation is still clouded, with the exact method of the payment of the German reparations undetermined. This uncertainty was reflected in the foreign exchange market, where rates were irregular and tending to decline. The British pound dropped to more than 13 cents below the recent high for the current year. The announcement of further dividend cuts by prominent industrial corporations was probably in part responsible for the lower prices for industrial shares. Railroad shares, on the other hand, showed some resistance to the downward movement on the strength of rather favorable earnings statements for the month of April, published last week, which, taken in conjunction with the wage cuts which are expected to take effect July 1, had a bolstering effect on the market.

MEN OF THE INDUSTRY

Charles W. Churchill, until recently general manager of the Winton Co., Cleveland, has joined the sales organization of the Buick Motor Co. In his new work with Buick Churchill will be closely associated with E. T. Strong, general sales manager, with headquarters at the main office in Flint. Churchill rose from retail salesman to general manager of the Winton company. In 1904 he became identified with Winton, where he gained valuable first-hand experience in selling cars. In 1906 he was made eastern manager of the company with headquarters in New York. His success in New York was so marked that after two years' experience as a branch manager he was recalled to Cleveland to take over the direction of the entire sales force. As general sales manager, the high calibre of his judgment and executive ability was evidenced and in 1915 he was promoted to general manager of the complete Winton organization, which position he held until joining Buick. Churchill has been a director of the National Automobile Chamber of Commerce for some time and has been chairman of the membership committee as well as chairman of the patents committee.

J. S. Garlent has been named factory manager of the Auto Wheel and Gier Pressed Steel units of the Motor Wheel Corp., at Lansing. Garlent joined the organization a year and a half ago, previous to which time he was factory superintendent for the King Motor Car Co.

Le Roy J. Williams has resigned as counsel and assistant to the general manager of the Lincoln Motor Co. He had been associated with the Lelands for the past six years.

Langdon A. Smith has been appointed vice-president and director of sales for the American Motors Corp., Plainfield, N. J., manufacturers of the American car. He has been connected with Maxwell-Chalmers interests for several years, latterly being assistant director of sales for the combined companies. D. M. Kingley has been appointed manager of the American's New York branch. He was vice-president and sales manager of Holmes and before that was associated with Locomobile.

C. W. Butterfield has been appointed sales manager of the Apex Motor Corp. He was sales manager of the Herschell-Spillman Motor Co., and also served for several years as sales and service manager of the Dyneto Electric Corp., Syracuse.

E. J. Mueller has been named director of sales and advertising of the Cleveland Motorcycle Mfg. Co. He had been connected with Harley-Davidson Motor Co. for eleven years, the last five as sales manager.

H. S. Dart, advertising manager for the Paige Motor Car Co., has resigned effective immediately. He has not announced his future plans.

O. L. Weaver has resigned as sales manager of the Star Rubber Co., because of ill health, but will continue as a director and secretary. A. G. Partridge, formerly vice-president and general sales manager of Firestone, has been named vice-president and sales manager of the Star company.

John T. Bowers has been appointed commercial manager of the Columbia Motors Co., Detroit. This is his first service in the automotive field, his sales experience to date having been almost exclusively in piano merchandising.

Wilson Bailey, formerly Eastern sales manager for the Gary Motor Truck Co., Gary, Ind., is now Eastern district manager of the Trackless Transportation Corp., New York.

W. C. Sills Resigns as Chevrolet Sales Chief

NEW YORK, June 1.—The Chevrolet Motor Co. announces the resignation of W. C. Sills as general manager of sales, effective to-day. Sills began his connection with Chevrolet in 1912, when he resigned from the Buick Motor Co. as assistant New England manager and started the distribution of Chevrolet cars in Boston and New England.

He moved to New York in 1914 and assumed the general direction of sales for the Chevrolet company. He has been, in a large measure, responsible for building up the strong organization now marketing the Chevrolet product.

Sills will return to Boston on Aug. 1 and resume distribution of Chevrolet cars in New England. He will be succeeded by Colin Campbell, who has been executive assistant to the general manager of sales for more than five years.

Colonel Cardway Resigns as Packard Export Head

NEW YORK, June 1—Colonel Fred Cardway has resigned as vice-president and general manager and director of the Packard Motors Export Corp. to devote all his time to personal interests. He has been a leading factor in the upbuilding of Packard international trade and his achievements have earned him a reputation as "one of the world's great business diplomats and psychologists."

Paul D. Davis, advertising manager, who for several years has been identified with the export sales promotion and advertising activities of Packard and the Firestone Tire & Rubber Co., has also submitted his resignation, as have Charles A. Cobb, assistant sales manager, and Paul F. Mulvey, secretary to Col. Cardway.

Rice Outlines Policies at Testimonial Dinner

DETROIT, May 27—H. H. Rice, who succeeded R. H. Collins as president and general manager of the Cadillac Motor Car Co., was guest of honor last night at a dinner in the dining room of the new Cadillac plant at which 400 of his co-workers were present. The meeting was presided over by G. H. Layng, vice-president of the Cadillac, and the committee in charge of the affair included C. M. Carson, industrial manager; F. A. Tresler, office manager, and J. A. Cleary, advertising manager.

All of the administrative officials, heads of the various departments throughout the factory, as well as foremen and assistant foremen, were present. The affair took the nature of a get-acquainted, get-together dinner, and Rice took occasion to outline some of the plans that would guide him in his efforts as the head of the Cadillac company.

Receivers Are Named for Portage Rubber

AKRON, June 1—George D. Bates and J. W. McGuire have been named receivers for the Portage Rubber Co. on a petition in bankruptcy filed against it by the Wellman, Seaver Morgan Co., which has a claim for $22,266. Total liabilities are listed at $1,700,000.

The receivership follows a hitch in the refinancing plans of the company. Creditors refused to assent to a plan of readjustment. The failure is due largely to heavy inventory shrinkage on raw materials and contractual losses for fabric and rubber.

Force Reduction Causes Lafayette to Sell Homes

INDIANAPOLIS, May 31—A group of fifty-six houses built by the Lafayette Building Co. here have been placed on sale by the company. The houses were primarily built for employees of the Lafayette Motors Co., of which the building company is a subsidiary organization, but because the plant has been forced to cut its force the houses are to be offered publicly for sale.

The houses are being sold for $1000 under the actual cash price and in some instances a greater loss is being taken. It is estimated that the company has suffered a loss of about $100,000 on the entire group, but it is thought that with a colony established the company will be able to utilize the remainder of the lots for building purposes and absorb the loss on their first group of houses.

The Union City Body Co. at Union City, Ind., is planning the construction of from twenty to forty houses on a site near its factory for employees, the houses to be sold on payments. The company plans to have the houses completed by fall.

TRUCK DIRECTORS TO MEET

DETROIT, May 28—Directors of the National Association of Motor Truck Sales Managers will meet June 7 to discuss improved sales methods among motor truck dealers and outline a plan of campaign to bring about a better understanding. Fred Glover, general manager of the Timken-Detroit Axle Co., and G. W. Yoeman, vice-president of Continental Motors, will attend the meeting and address the directors. Many reports that have reached the association headquarters regarding the activities of some dealers not in accord with good business principles, resulted in the decision of the directors to make an effort to bring about betterment through persuasive methods, if possible. In the event of failure, drastic measures will be taken, it is said, to bring such practices to an end.

Calendar

SHOWS

Sept. 5-10—Indianapolis, Automobile and Accessory Show in conjunction with Indiana State Fair, conducted by Indianapolis Automobile Trade Association, John B. Orman, Mgr.

Sept. 28 - Oct. 8 — New York, Electrical Exposition, 71st Regt. Armory, Electric Equipment, Machinery and Vehicles.

Nov. 27-Dec. 3—New York, Automobile Salon, Hotel Commodore.

January — Chicago, Automobile Salon, Hotel Drake.

FOREIGN SHOWS

June, 1921—Reykjavik, Iceland, Agricultural Exhibition—Agricultural Machinery—Icelander Agricultural Society, Reykjavik, Iceland.

September—Buenos Aires, Argentina, Passenger Cars and Equipment. La Pabellon de las Rosas. Automovil Club Argentino.

September—Buenos Aires, Argentina, Cars, Trucks, Tractors, Farm Lighting Plants and Power Farming Machinery. Palermo Park; Sociedad Rural Argentina.

September—Luxemburg, Luxemburg, Agricultural Sample Exhibition.

Oct. 5-16—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

Nov. 4-12 — London, British Motor Show, Society Motor Mfrs. and Traders.

May, 1922—Quito, Ecuador, Agricultural Exposition, celebrating Centenary of Ecuador. Automotive Section.

CONVENTIONS

July 4-9 — Mackinac Island, Mich., Summer Meeting Automotive Equipment Association.

Oct. 12-14, 1921 — Chicago, Twenty-eighth Annual Convention National Implement & Vehicle A'ssn.

Nov. 22—New York, Convention of Factory Service Managers, National Automobile Chamber of Commerce.

RACES

June 18—Uniontown, Pa., Speedway Events.

July 25—Grand Prix, Le Mans.

Labor Day—Uniontown, Pa., Autumn Classic.

Death of Batchelder Shock to Motordom

(*Continued from page* 1186)

Batchelder was born at Akron, N. Y., 52 years ago, and was educated at Attica, N. Y. He began life as a printer at Attica and one of his cherished possessions was a gold plated printer's stick. After learning his trade in Attica he went to Buffalo and became a compositor on the Buffalo *Courier*. He was an enthusiast on sports and became sporting editor of the *Courier*. His page was widely quoted and he was regarded as an expert in various branches of sport. But his chief interest was in bicycles.

He came to New York 27 years ago as a handicapper for the League of American Wheelmen. He also served as bicycle editor of the New York *American* at a time when cycling was in its heyday. Four or five years after coming to this city he was made chairman of the National Cycling Association, which controlled racing throughout the country.

Just as he had been a pioneer in the promotion of the bicycle, Batchelder became one of the first automobile enthusiasts in the days when few foresaw the future of the motor vehicle. He studied automobiles thoroughly and made the acquaintance of the men who did most to develop the industry in its early days. He was one of the first to grasp the importance of highways.

When Alfred Reeves resigned as automobile editor of the *Evening Mail* his position was taken by Batchelder, who later became editor of *The Automobile* and then took up his work with the A. A. A., which then was an infant organization.

Batchelder took with him into the development of the national association of motorists the enthusiasm which had marked his entire career. While intensely interested in every activity and development which related to motor vehicles he concentrated his major energies on highways and soon became one of the foremost exponents of this subject.

Just as Batchelder had progressed from the bicycle to the automobile, he was turning to aviation. He had visions of great national highways gridironing the country to be utilized by aviators and motorists alike. He had long contended that aviators could follow these roads and that they should be lined from coast to coast and from border to border with landing places. One of the principal speakers at the annual dinner of the A. A. A. at Washington two weeks ago was Brigadier General Mitchell of the Army Air Service who advocated the building of landing fields. It probably was the lack of a suitable field upon which to land that cost Batchelder and his companions their lives on the ill-fated flight from Washington to Langley Field in a Curtiss Eagle ambulance airplane in a terrific electrical storm.

Steel Tread Tires Pass Out in France

(*Continued from page* 1181)

of leather used for receiving the steel rivets. The curious feature is that without any publicity campaign the French motoring public should have been induced to abandon a type of tire which not long ago was considered essential.

Clincher bead tires still hold the market, with no likelihood of their immediate abandonment in favor of the straight side. Michelin, the biggest manufacturer in France, is conducting a campaign against the straight side and has circularized all his dealers to fight it. According to reliable information, however, Michelin has a straight side tire ready to be put on the market if the move is considered advisable.

At the present time this change could only be made at immense expense and with the aid of a big propaganda campaign, for the public would refuse to buy cars with straight side equipment unless assured that supplies could be obtained in all parts of the country. There was a certain possibility of straight side tires getting a footing in France by reason of American army automobiles being put on the market, together with stocks of American tires. This opportunity has been lost, however.

PACKARD AWARDS WATCHES

DETROIT, May 28—The Packard Motor Car Co. Wednesday night presented to each of its employees who had served ten years or more a gold watch, among the recipients being President Alvan Macauley.

Shippers Association Invites Automotive Men

PITTSBURGH, May 28 — Manufacturers of automobiles and automotive equipment, who make use of the public merchandise warehouse in distributing their products, will be interested in the annual meeting of the Shippers' Warehousing & Distributing Association to be held at the William Penn Hotel here on June 16 and 17.

The association was organized last June by manufacturing interests which route their goods from factory to retailer and consumer by way of the public warehouse. The warehouse industry itself has for thirty years had a national organization, the American Warehousemen's Association, but shippers who had business dealings with that industry had no organized means of adjusting differences with warehousemen. The recognized need of standardization of documents and practices in this business relationship has attracted to the shippers' body such companies as the Westinghouse Electric & Manufacturing Co., American Sugar Refining Co., Colgate & Co., Lever Brothers Co., De Laval Separator Co., Horlick's Malted Milk Co., Kellogg Toasted Corn Flake Co., Procter & Gamble Distributing Co. and others.

Automotive interests which use public warehouses are eligible to membership and their representatives will be welcomed at the convention. Information regarding the program may be obtained by addressing the association's secretary, Kent B. Stiles, editor of *Distribution and Warehousing*, 239 West 39th Street, New York.

WILLYS MOVES EXPORT OFFICE

NEW YORK, May 31—Removal of the administrative offices of the John N. Willys Export Corp. from 165 Broadway to the Willys headquarters at Toledo on June 15 was announced by the company here to-day. A branch office will be maintained at New York but the export business will be directed from Toledo by E. C. Morse, vice-president and general manager. The export corporation will be continued and will not be merged into any of the other Willys subsidiaries. The company handles foreign sales on all the products of the Willys companies.

AUTOMOTIVE INDUSTRIES
THE AUTOMOBILE

VOL. XLIV. NEW YORK—THURSDAY, JUNE 9, 1921 No. 23

The Stage Is Set—Now for a Selling Campaign

With practically all prices adjusted to the sentiment of the times and the cost of manufacture, the job remains to sell the public and get the business. Secretary Hoover getting ready to help. Points out importance of automotive facts to other industries.

By Clyde Jennings

TWO major events of last week indicate rather definitely the task immediately ahead of the automotive industry. The first was the unofficial expression of opinion gathered during the N. A. C. C. meeting, which was of much more importance than the meeting itself; the second was the meeting of representatives of the industry with the Secretary of Commerce. Both indicate that, now that the stage is set, it is time to quit talking troubles and to sell automobiles.

The BIG IDEA has finally got across to the automotive industry. Here, there and everywhere prices are being adjusted. There was not a man at the National Automobile Chamber of Commerce annual meeting last week who was not outspoken in the sentiment:

> **"It is up to the industry to settle the price question right now and end the feeling of uncertainty that exists in the public mind. People do not buy on a falling market and we must stabilize values immediately."**

The N. A. C. C., of course, did not discuss prices, nor did the members attempt to indicate to each other what should be done. But all of the king's horses and all of the king's men could not have stopped the conversations between the men present when they were not in meeting.

Sales (and, of course, prices) were uppermost in their minds. As far as public expression goes they were all of a mind. Some laughed at the idea that an expression from the N. A. C. C. would help the situation. Instead of favoring such action, the sentiment was about like this:

> **"The manufacturer who is not sold on the necessity of clearing the atmosphere on price questions need only consult his own sales department and get an expression from his dealers. Perhaps his competitor announces a price cut. The next morning he gets a bunch of telegrams cancelling shipping orders for his cars. The dealer knows what prospective sales are competitive and he knows which he has lost, or will be delayed. So he stops deliveries for these cars.**
>
> **"Or, if he cuts the price of his own cars, he gets telegrams asking for shipments, because the dealer knows what prospects are holding back merely because of price.**

"No matter whether the manufacturer has cut or not, he can easily get the importance of price to present day sales."

That is about the way the industry stands at present. "Cut and cut now" was the unofficial and unanimous sentiment when the leaders were together.

And the flock of price announcements that came in left no doubt but that they were acting on their best judgment.

There is, however, a second chapter to this movement that is quite as important as the price cutting.

This is to justify the present price. How many times have you read advertisements during the last few months that announced "the last, final reductions" on clothing or other commodity. It is possible that the public will still be suspicious after reading the new prices. You can't blame the public if it is. For months and months the public has been fed on information as to war profiteers, speculations that were boosting prices, news of industrial and labor organizations that were upholding purely fictitious prices, the greed of landlords and many other things. There must be some sane, honest statements to counteract the opinions left by this long siege.

These sane, honest statements can be applied to automotive vehicles. We believe that this industry is honest and that it is merchandising its products honestly. It is giving honest value and it has, in the main, written off its share of the losses.

Then why not convince the public of this?

Why not let every automotive advertisement come out strong with honest value statements?

Why be afraid to discuss the real value of the car or the truck?

All hands will have to admit now that the effort to do business on the 1920 plan failed because the attitude of the public had changed. The seller must meet the attitude of the buyer. He must convince the buyer. Foolish publicity, such as serves when the buyer meets the attitude of the seller, will not serve the purpose for this.

The entire industry needs honest, substantial publicity. Despite all that has been said and done in the last five years, there are many who dare to doubt the utility of the industry. These folk must be convinced. The individual who buys a vehicle must be convinced that he has made a good buy.

There were other happenings of the week that worked to the same conclusion that the industry has reached in the slow course of reasoning that has governed it since "FORD DID IT" last fall. The entire course of development was plain to all who wanted to study the future then. Some were reactionary; some did hasty things; now all realize that the best thing to have done then was to write off the loss.

A lot of manufacturers who wanted the public to share in the losses have found that the public was of a different mind. The public became discriminating and bought of those who made the best practical showing—and you cannot convince any man to-day that price is not a practical argument.

There is one consolation to be gained—and that is that the public apparently is sold on the honesty of manufacture of the entire industry. This is shown in the inclination of the public to follow the price, regardless of previous choice of car. If the car they wanted did not cut, then they bought the one that did.

But to get back to the other happenings.

Credit Now Ample

W. P. G. Harding, governor of the Federal Reserve Bank, spoke to the N. A. C. C. He did not say anything about the prices of automobiles in so many words, but he did say much about price trends. Also he vouched for the statement that the public held a tremendous buying power to-day. He said that the changed conditions had brought about a buyers' market in all lines, and he thought that this was a beneficial state of affairs. He frankly favored a buyers' market because it brought out the best that was in the seller, both as to methods of manufacturing and marketing. The governor reviewed the history of finance, from the banking standpoint, since the beginning of the war, and dwelt especially on the period following the war. This review is more or less familiar, but his conclusion was new. It was, in effect, as follows:

AFTER setting forth that the credit foundation had now been laid for new activities, Governor Harding in his address to N. A. C. C. members suggested the revival of the slogan: Business as usual.

He said this slogan was tried during the first days of the war, but was dropped when it was found to be impractical. Now, he suggested, was a very fine time to revive it and to let the optimists do the talking. In this connection he said:

"Just at present the pessimist is entirely too prominent. The pessimist is a very useful person. He keeps us from running away with ourselves. He should have been listened to a year or more ago. Just now he should be silenced.

"My personal objection to a pessimist is that he operates best at the wrong time."

The banks are now in excellent position to help any helpful business. They have the proper basis for extending credit and there is no reason for any discrimination between helpful industries. In some quarters business is dragging, and you automotive manufacturers should strike out boldly to push business. Your business to-day is very large; it has many ramifications, and if you will do your best to help business you have a great power for good and it will not be long before all lines of business are responding.

Meet with Secretary Hoover

The next day came another move in the same direction. It took place in Washington, where a number of automotive manufacturers met with Secretary of Commerce Hoover at the latter's invitation. J. Walter Drake acted as spokesman for the manufacturers. At the opening of the meeting the manufacturers were just a bit doubtful as to what Secretary Hoover wanted with them and how he was going to get whatever it was that he wanted.

The Secretary quickly allayed any suspicion by stating his position quite clearly. He said at the outset that he wanted only the figures that would be helpful to business, but he told the automotive manufacturers that their industry had become of such importance in the business world that other industries were asking for their figures showing the status of the industry.

The accuracy and excellence of the present automotive industrial figures were conceded by the Secretary, but he said that to other industries they would be much more valuable if they were given by price classes. He also

made it clear that he was not interested in the figures of any one factory, but in figures that were representative of the industry. He did not even care how these figures were gathered, except that the data be accurate.

In explaining his dealings with the National Automobile Chamber of Commerce, Secretary Hoover stated that he was entering upon this alliance because it was his information that this was one of the really helpful industrial organizations and is, and has been, clear of doubtful business practices. He said that some trade organizations could not be considered in this relation because their activities were chiefly in restraint of trade, rather than a promotion. He expressed his pleasure in meeting an industrial committee that comprised association members as well as non-members. He said that he was quite willing that the N. A. C. C. should be the chief agent in gathering statistics, and that he wanted such statistics as the individual manufacturers could see the benefit of. He had no desire to force figures from an industry.

It was practically agreed that the monthly shipping figures comprised the data that other industries were chiefly interested in. Drake informed the Secretary that the practice of the industry was to regard future orders, or annual sales contracts merely as a means of allotment and not as "future orders." It was Drake's thought that the shipping figures were the only informative data, and that these could be separated into price classes, also the percentage of closed cars could be given by classes.

NOT much has been said recently about the prices of trucks.. The faster moving passenger car is the center of attraction and is experiencing a revival of selling.

Here is a curious result. Early this week a truck man came to talk over the prospects and, after considerable discussion, he remarked:

"We are very much afraid someone will start a price cut on trucks."

Evidently the passenger car is faster than the trucks in other than road operating speeds.

Drake presented to the Secretary the industry's request for information from other branches of trade. He said that additional steel figures were needed, also crop statistics, figures showing the status of the meat packing, textile and shoe industries and accurate and prompt reports of railroad passenger miles and railroad freight ton-miles. The Secretary said that he thought these figures would form a part of the complete picture of business that the Department contemplated publishing, once the facilities were equal to the task that the Department had undertaken.

While discussing this question the need of more detailed export and import figures was taken up. Drake said that the manufacturer wanted to know what kind of motor cars were going to a certain country. The Secretary said that this need had early impressed him, but that to get the port figures classified properly it was necessary that this service be transferred to the Department of Commerce. This work was now under the Treasury Department. He said that some time ago **he and Secretary Mellon thought they had adjusted this phase of the work, but that the comptroller had decided that, while they might shift the labor from one department to the other, they could not shift the appropriation.** Now it was necessary to await a new comptroller. The Secretary made no further comment on this, but after the meeting had adjourned the manufacturers who were present talked it over at length as an illustration of business methods of government.

The Secretary said that in time he hoped that export figures would be classified in a way to be most helpful. He told of speeding up the compilation and publication of foreign trade figures.

Another matter of considerable importance was the naming of two men to be placed in the Department of Commerce to represent the industry while the new plans for the promotion of domestic and foreign sales were being carried forward. First the Secretary wanted as a trade advisor in the Bureau of Foreign and Domestic Commerce a broad-gage salesman who could form the plans upon which statistics were to be gathered and used both at home and abroad. This man would also help to educate the traveling agents who will go to other countries to look into trade prospects. This man, said the Secretary, must be a man who, in private life, can earn several times what the Department can pay him. He must be a very self-sacrificing individual for a period of perhaps a year while the Department is being educated. This obligation was assumed by the representatives of the industry.

Another man is wanted for the Bureau of Standards. This man, the Secretary said, should be both an engineer and production man. The idea behind this appointment was to make the Bureau of the utmost practical value to the industry. The salary in this job will be utterly out of keeping with that which the man wanted would earn in industrial employment. The manufacturers promised to suggest such a man, but said they would probably consult the Society of Automotive Engineers on this, as they had regarded the Bureau of Standards as the engineering branch. Secretary Hoover said he was quite anxious to make this Bureau of practical manufacturing value to the industry.

An interesting point was raised when the Secretary asked if it was possible to report periodically on production as a percentage of capacity. The manufacturers said they were at a loss to measure capacity and did not feel that they could make an accurate report on this.

At the conclusion of the meeting Drake offered to submit to the Secretary at once a memorandum setting forth the extent to which the industry could co-operate in the effort to broaden and stabilize business generally and what the industry needed for the same purpose. He also said he would forward suggestions for appointment to the two positions at the same time. The Secretary said that this course was satisfactory to him.

Those present were: J. Walter Drake (Hupp), Alfred H. Swayne (G. M. C.), A. T. Waterfall (Dodge), E. A. Williams, Jr. (Garford), Gaston Plaintiff (Ford), J E. Kepperley (Overland), H. S. Vance (Studebaker), R. A. Hauer (International), M. L. Hemmingway (M. A. M. A.), Pyke Johnson and John C. Long (N. A. C. C.), T. F. Cullen (Chilton Pub. Co.), Clyde Jennings (Automotive Industries).

THERE are 107 agencies for foreign cars in Holland. American manufacturers have the largest representation with 37. It is estimated that there are now about 10,000 passenger cars in use throughout Holland; 3000 American cars went into that country during 1920 alone.

New Federal Is Heavier and More Powerful Than Earlier Models

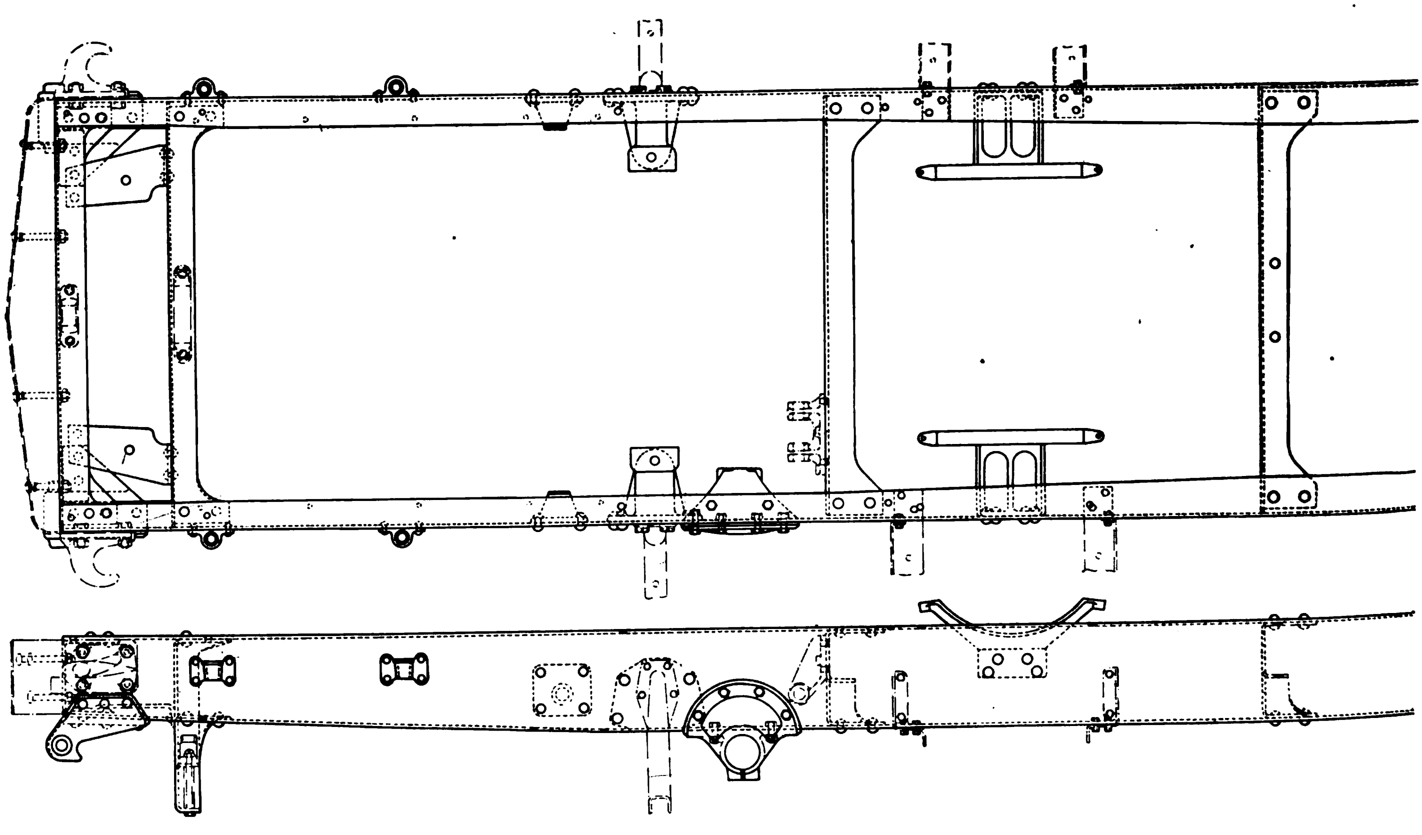
Five to six ton job is equipped with new Continental engine which develops 50 hp. at 1100 r.p.m. and has full pressure lubrication. Other equipment includes lighting generator, vacuum fuel feed, Eisemann magneto, Pharo governor, hub odometer and Alemite grease attachments.

By J. Edward Schipper

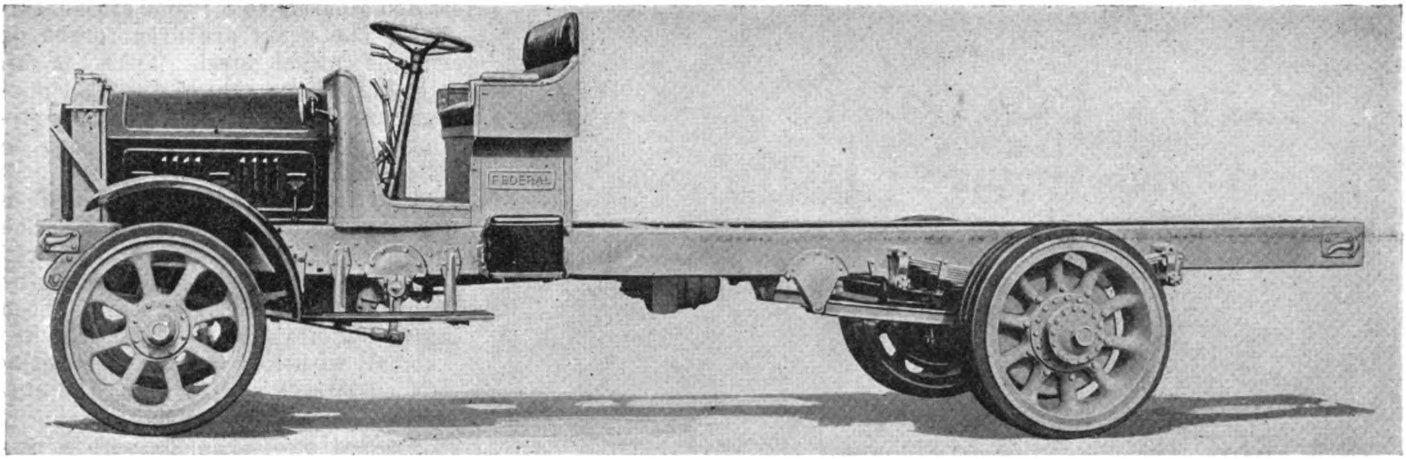
A NEW 5 to 6-ton Federal truck, incorporating a number of features of advanced design, is about ready for the market. As compared with the older 5-ton Federal, the new truck has a larger engine, the displacement being 425 instead of 350 cu. in. This engine has a removable instead of a fixed cylinder head, larger crankshaft bearings and full pressure oil feed instead of circulating splash. Electric lights and horn are furnished in place of oil lamps and a hand horn, and provision is made for an electric starter. The truck has a 14-in. instead of a 12-in. clutch, a larger propeller shaft, a heavier frame and a heavier transmission, with less reduction in the rear axle and increased reduction in the transmission, thereby attaining greater speeds in high gear without sacrifice of power in the lower gears. The new truck also comes with better equipment, being provided with four towing hooks, vacuum feed in place of gravity, and a hub-odometer.

The engine used is a new Continental model. It has been designed particularly for heavy work, being a four-cylinder, 4¾ by 5 in. design, developing 50 hp. at 1100 r.p.m. The cylinders are cast in pairs with removable heads. One of the features of the cylinder castings is the exceptionally large water jacket, the depth of which is even noticeable from the outside, giving a rather fully rounded casting. The crankcase is of aluminum, and the aluminum oil pan is bolted to it. The flywheel housing is cast integral with the crankcase and oil pan. The engine has a three-bearing crankshaft, 2⅝ in. in diameter. The end thrust of the crankshaft is taken on the front bearing and an adjustment for end play is provided. The reciprocating parts are completely machined for balance, and both the pistons and connecting rods are of extra length to reduce side thrust per unit of bearing surface on the cylinder wall. Each piston is equipped with four ¼ in. piston rings.

The gear train at the front end of the engine consists of four instead of the conventional three gears. The



Plan and side view of frame



New Federal 5-6 ton truck, which is generally heavier and more powerful than the former 5-ton Federal.

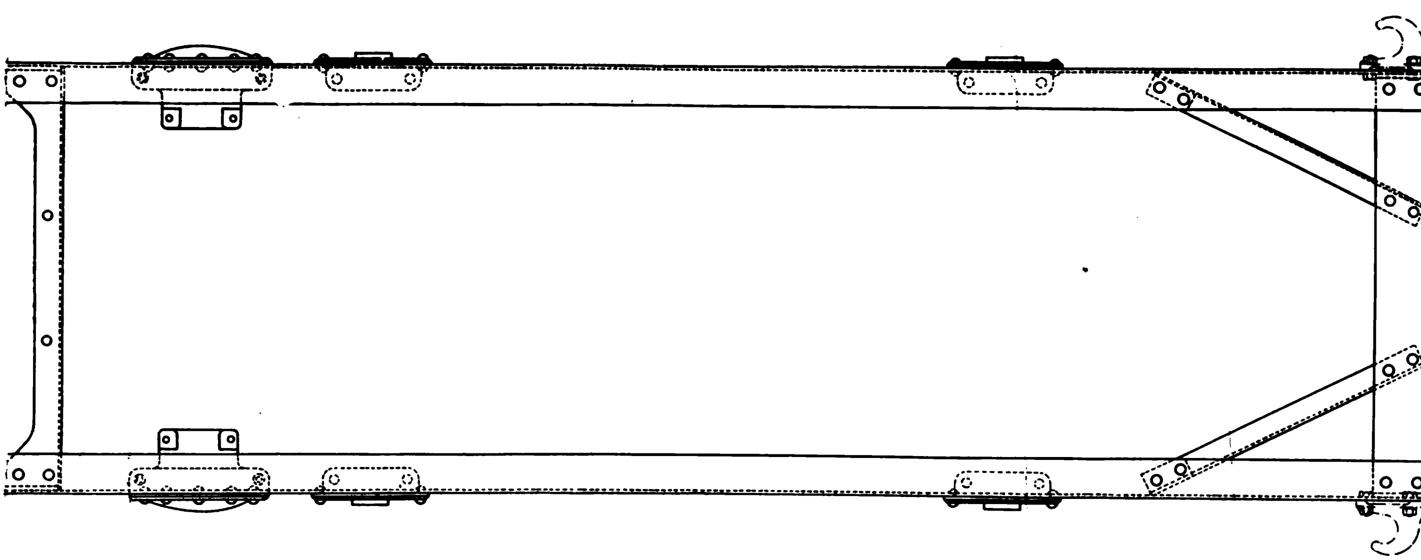
use of an idler gear between the cam and pump gears and the crank gear makes it possible to distribute the accessories, such as the pump, generator and magneto, so that they can be accessibly installed. Three bearings are employed for the crankshaft, which is 1¼ in. in diameter between the cams. It is machined and ground on special machines and the diameter of the camshaft at the bearing is greater than the height of the cam, to permit the removal of the shaft without disturbing the bearings. The valves are on the right side of the engine and are 2 1/32 in. in diameter. The valve stem diameter is 7/16 in.

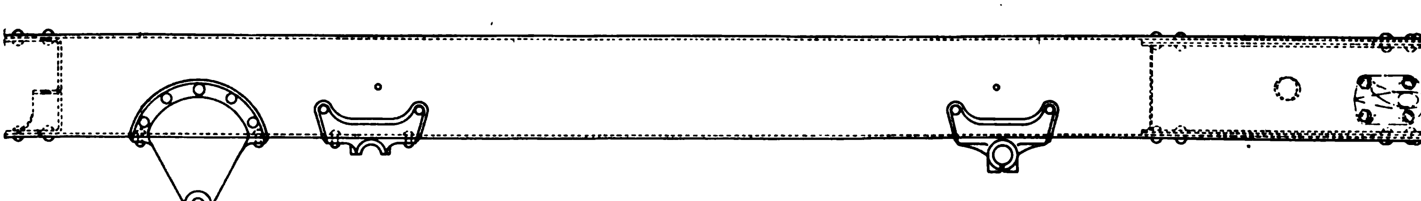
Cooling is provided for by centrifugal water pump so mounted that there is ample room for taking up and replacing shaft packings. The pump is on the left side of the engine on the water pump and magneto shaft, which are driven off the same gear which supplies the drive to the fan pulley.

Full pressure feed oiling is secured by a gear pump, driven by spiral gears from the camshaft. The oil pump draws oil through a strainer in the oil pan. From this pump oil leads run to all the main bearings and the timing gear case. The crankshaft is drilled to supply oil to the connecting rod bearings, and an oil duct carries the oil from the lower end of the connecting rod to the piston pin bearing.

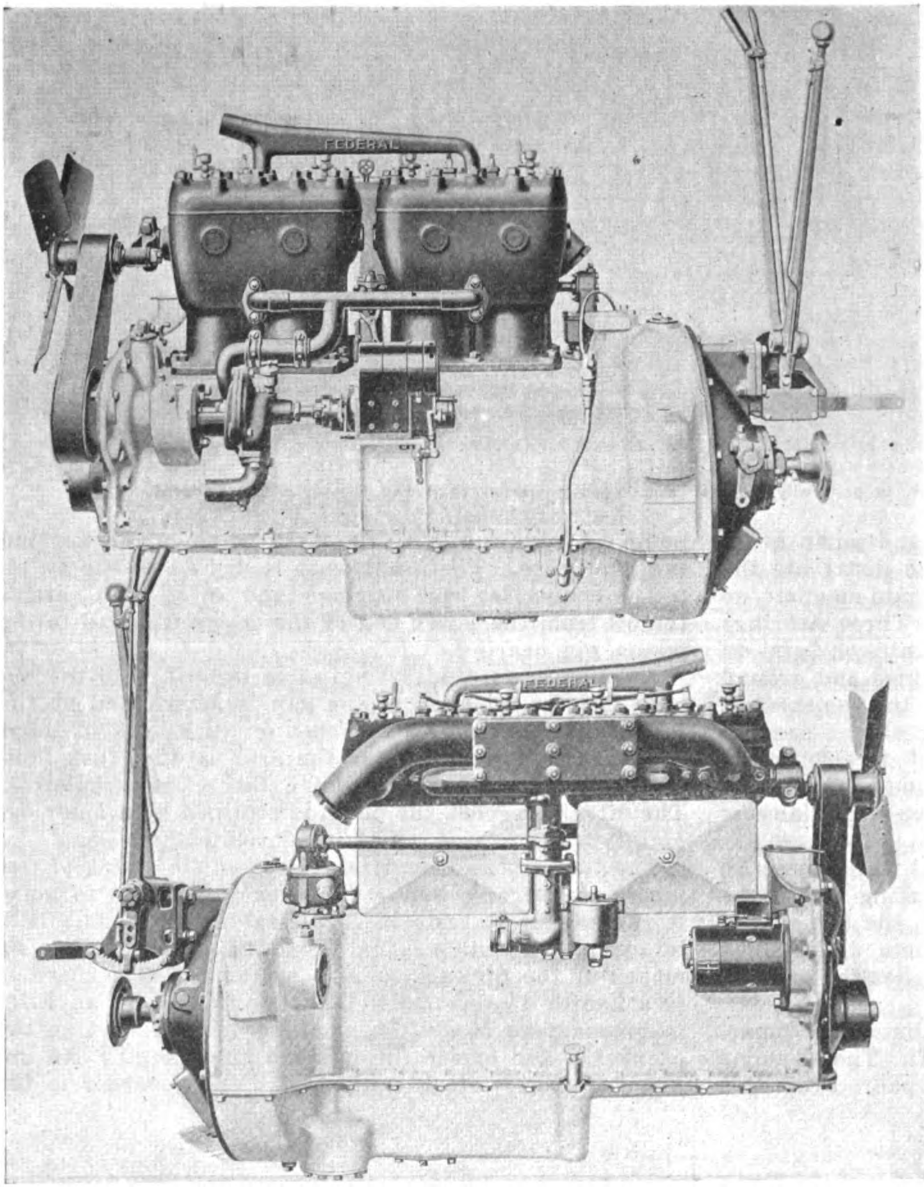
An oil pressure adjusting valve is built into the engine and the oil level in the pan is determined by the use of the conventional bayonet or stick type of gage. A pressure gage located on the dash of the truck indicates the pressure under which the oil is circulating. The oil which feeds the pump is strained by a non-clogging type of strainer which is carried in the oil pan.

The fuel system comprises a pressed steel tank of two pieces electrically welded together and tinned to make it rustproof. It rests in a malleable iron saddle held by straps. Gasoline is fed from this to the engine by means of the Stewart vacuum system. The carburetor is a Zenith 1½-in. model L-6. Ignition is by an Eisemann magneto Model G4, mounted on a bracket on the crankcase and driven through the pump shaft. An impulse starter is stock equipment. The governor is the





with all brackets in place.



Two views of the new Continental 4-4¾ x 5 in. truck engine fitted to the new Federal truck.

Pharo, a centrifugal device using oil as the medium subjected to centrifugal force. The pressure of the oil raises a piston, which closes a butterfly valve in the intake pipe.

Three-point suspension is used for the engine, the front end being supported by a circular trunnion cast integral with the timing gear case and resting in a saddle bolted to a cross member. The two rear engine arms are supported on brackets riveted to the frame members. One of the rear arms is flexibly mounted by means of a coiled spring used in connection with the hanger bolt.

A Borg & Beck clutch 14 in. in diameter is fitted. The clutch shaft is 1¾ in. in diameter and is milled with 10 splines. Throw-out thrust is taken by a ball thrust bearing. The clutch shaft is mounted on two ball bearings and lubrication of these bearings and the throwout sleeve is provided for by a drilled clutch shaft through which grease is forced to the bearings.

The four forward and one reverse speed ratios of the transmission are as follows: High, 1 to 1, third, 1.75 to 1; second, 3.22 to 1; first, 5.85 to 1, reverse, 6.8 to 1. The gearset is mounted amidships and is supported at three points, two in the rear and one at the front. The front support is flexible, while the two rear supports are bolted securely to a frame cross-member. The gears are drop forged of chrome nickel steel. There is an opening on the side of the transmission case, through which, by removing a plug, the transmission can be filled with oil.

Provision for a power take-off is made on both sides of the case. The drive shaft between the clutch and transmission and that between the transmission and rear axle, both carry two universals. The shafts are tubular, with forged stubs electrically welded to each end to which the universal joints are attached.

Pressed steel channels with a section 9 in. deep by 9/32 in. thick are employed for the frame. The latter is reinforced at all corners and at the junction of the frame cross-members is provided with heavy gusset plates. The frame is hot riveted and all the rivet holes are drilled. The truck is made in three chassis lengths with wheelbases of 163 in. on two of them and 187 on the third. The two with the 163-in. wheelbase have loading spaces of 130 in. and 154 in. respectively. The 187-in. wheelbase chassis had 190-in. loading space. These trucks all have the same over-all length of the frame, 222 in.

A Gemmer steering gear is employed and the control levers for the spark and throttle are mounted on the steering post. The steering gear, clutch, pedal and service brake pedal are on the left side. The gear shift lever and the emergency brake lever are mounted in the center.

The 5 to 6-ton model is equipped with generator, 6-volt battery, two side lamps with diffusing lenses and a tail lamp. A feature of the equipment is the mounting of the tail lamp in a recess of the rear frame member and of the license plate on the rear frame in such a way that it is illuminated by the tail light.

The axles are Timken type, mounted on roller bearings throughout. The rear eye of the front spring is slightly lower than the front eye, thus providing a caster effect. The rear axle is a full floating worm type,

A Possible Explanation of Airplane Accidents Attributed to Engine Trouble

Formation and collection of snow in inlet manifold is known to cause throttling and erratic engine action. The trouble can be remedied by slightly heating the incoming charge with but slight loss in power.

By Stanwood W. Sparrow*

WHEN the daily paper tells that a plane has crashed, and states a definite cause such as the fracture of a fuel line or the collapse of a wing, public confidence in the safety of aviation is shaken. It is easy to believe, however, that defects so glaringly revealed will be corrected at once. The real blow to aviation comes when no satisfactory explanation for the accident is forthcoming. Knowledge of what is wrong must precede any intelligent effort to make a thing right. A wrecked plane bearing mute testimony to the existence of a fault and a confession of ignorance as to the nature of the fault tends to contradict assertions that aviation has outgrown the experimental stage. To bring attention to one possible cause of such unexplained accidents this note has been prepared for the National Advisory Committee for Aeronautics.

In testing airplane engines at the Bureau of Standards it has happened frequently that engine performance became erratic when the temperature of the air entering the carbureter was between 0 deg. C. (32 deg. Fahr.) and 20 deg. C. (68 deg. Fahr). Investigation revealed the trouble to have been caused by the formation and collection of snow somewhere between the entrance to the carbureter and the manifold, probably at the throttle. Experiments in the carbureter test plant had shown the possibility of this trouble. In fact, a glass portion of the induction system made it possible for one actually to see the snow as it collected.

Proof scarcely less convincing was obtained during engine tests. That something was wrong became apparent from a drop in power. The manifold depression, the difference between atmospheric pressure and the pressure in the manifold, was greater than that usually obtained at full throttle at this speed. At the same time, measurements showed the rate of air flow to be lower than usual. Inasmuch as both of these effects would be produced by throttling the engine, they gave a clue to the source of trouble. In some cases the snow would continue to collect until it shut the engine down, while at other times after it had effected a decrease in power of from 25 to 50 per cent a portion would become dislodged and the engine would speed up. The test apparatus is arranged so that the air on its way to the engine passes over heating grids. If, while the power was still low, sufficient heat was applied to increase the air temperature 20 deg. C. (36 deg. Fahr.) the power, manifold depression and air flow would soon regain their normal values. A few rather violent fluctuations of speed usually accompanied this period and can be attributed to the water passing into the combustion chamber as the snow melted.

*Of the Automotive Powerplant Section of the Bureau of Standards. This paper is issued as Technical Note No. 55 of the National Advisory Committee for Aeronautics.

Granting this trouble to be caused by the condensation of moisture from the air and the subsequent formation of snow, the removal of the moisture should prove as effective a cure as an increase in temperature. Fortunately it was possible to do this and thus check the validity of this supposition as to the origin of the trouble. The engine test apparatus includes refrigerating coils which enable all the air taken by the engine to be cooled to below —20 deg. C. (—4 deg. Fahr.). This air is then reheated to the desired temperature. Air when cooled to —20 deg. C. (—4 deg. Fahr.) contains almost no moisture and no opportunity is offered for it to collect any during its passage from the heating grids to the engine. Under these conditions, the engine operated satisfactorily at these temperatures at which difficulty was experienced with the air from which the moisture had not been removed.

The more serious the manifestations of this trouble, the more difficult it becomes to secure accurate data for record. Fluctuations of speed are violent and a stalled engine is usually the final result. A record of a few instances where it was possible to hold the speed reasonably constant are given as examples of the trouble in its milder stages. On Feb. 14, 1921, with the engine operating at part throttle at 1800 r.p.m. it was noted that the power was decreasing. At 1:06 p. m. readings of carbureter air temperature and manifold depression showed the former to be 10 deg. C. (50 deg. Fahr.) and the latter 25.0 cm. (9.84 in.) of mercury. Heat was applied and at 1:08 p. m. the air temperature had risen to 38 deg. C. (100 deg. Fahr.) and the manifold depression had dropped to 6.8 cm. (2.68 in.). Again the temperature of the air was allowed to drop and again a drop in power and increase in manifold depression resulted. With the speed maintained at 1800 r.p.m., the throttle was opened wide and readings taken showing the air temperature to be 10 deg. C. (50 deg. Fahr.), the manifold depression 11.1 cm. (4.37 in.) and the brake horsepower 86. Within two minutes, the application of heat had resulted in dropping the manifold depression to 5.6 cm. (2.20 in.) and in raising the brake horsepower to 185. The foregoing results were all obtained at air densities corresponding to ground level. Similar conditions were found on Feb. 23, at an air density corresponding to an altitude of 5000 ft. with the engine operating at full throttle at 1600 r.p.m. With the air at a temperature of 30 deg. C. (86 deg. Fahr.), the manifold depression was 2.9 cm. (1.14 in.) and the brake horsepower was 156. Eight minutes after the heating was discontinued, the air temperature had become 8 deg. C. (46 deg. Fahr.), the manifold depression 5.1 cm. (2.01 in.) and the brake horsepower 120.

While in all of these instances it was a change in weight of charge that caused the drop in power, the mag-

nitude of the decrease may have been influenced by another factor, a change in mixture ratio. If a carbureter does not maintain the air-fuel ratio constant at reduced loads, any unintentional throttling involves a departure from the desired mixture quality as well as a reduction in mixture quantity. To the reader familiar with carbureters in which changes in the area of a small passage between the float chamber and throat effect the mixture ratio changes, still another source of danger has doubtless suggested itself. This danger is that a collection of snow may block the connecting passage and cause a serious change in air-fuel ratio.

Discussion thus far may have emphasized unduly loss of power instead of what is probably the more serious effect, excessive fluctuations in power. Under these conditions a pilot is in exactly the same position as though his engine were controlled by a lunatic, opening and closing the throttle at will. Yet, in case of an accident, before an examination could be made the snow would have melted, leaving no evidence to confirm the pilot's report of trouble.

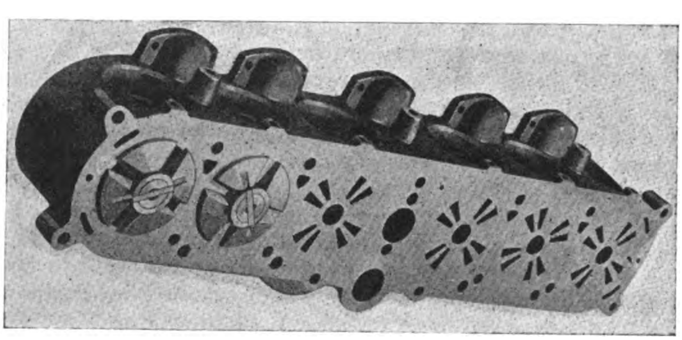
It is hardly worth while to attempt to predict from theoretical considerations at what temperature the trouble from snow formation will be most pronounced. It does seem desirable, however, to consider how much additional external heating is necessary to give reasonable assurance that the trouble will not occur. The weight of water vapor that a unit volume of air can contain decreases with decrease in temperature and the surplus condenses. Obviously if the drop in temperature be prevented there can be no condensation. The problem is to supply sufficient heat to completely vaporize the fuel so that no heat for this purpose need be withdrawn from the mixture. If the heat of vaporization of aviation gasoline be 75 cal. per gram (135 B.t.u. per pound)* complete vaporization will produce a drop in mixture temperature of 26 deg. C. (47 deg. Fahr.) with an air-fuel ratio of 10 to 1 and a drop of about 14 deg. C. (25 deg. Fahr.) with an air-fuel ratio of 20 to 1. It is safe to assume that the mixture ratio used will fall within these limits. The above calculation assumes all the fuel vaporized and all the heat used in vaporizing the fuel to be supplied by the mixture, while usually a portion of this heat is supplied externally. From these considerations it appears that the addition of an amount of heat sufficient to increase the mixture temperature 25 deg. C. (45 deg. Fahr.) should prove a reasonable guarantee of immunity from this trouble. The power loss that this would entail should not exceed 5 per cent.

This note is not intended as a sweeping recommendation of additional air heating for every airplane engine. Such a course would be akin to prescribing medicine for a patient without first being assured that he was really sick. The aim is to call attention to a "disease" to which aviation engines are subject, to describe its symptoms, and to emphasize its seriousness. Methods of prevention or cure can be consigned with safety to those vitally concerned.

*Ricardo, *Automobile Engineer*, February, 1921.

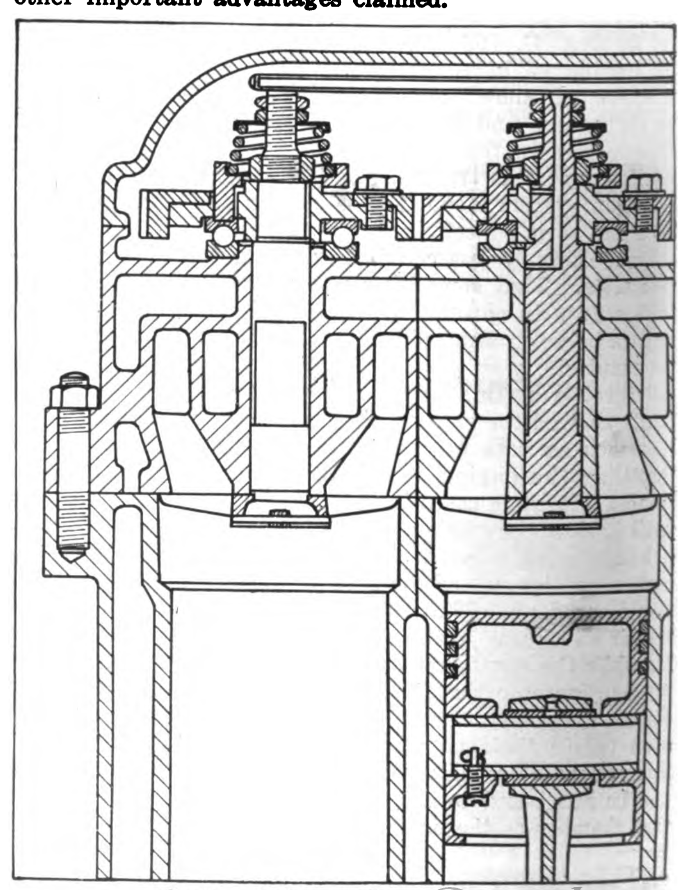
Disk Valve Engine Used in New Car

ONE of the passenger cars marketed for the first time this year is known as the Ace, and the principal feature of this car is the Guy rotary disk valve engine. The disk is located in the combustion chamber. It bears against the cylinder head and is provided with four radial, rectangular slots forming ports. In the cylinder head there are four corresponding inlet and four exhaust ports. As the inlet ports, for instance, are opened every time the slots in the valve disk register with the inlet ports in the cylinder heads, which happens four times during one revolution of the disk, and as they need to be opened only once every two revolutions of the crankshaft, the disks revolve at only one-eighth the crankshaft speed. This low speed of rotation seems to be the chief novelty. The inlet and exhaust ports are located adjacent to each other. Inlet and exhaust ports lead to two concentric passages with outlets on opposite sides of the cylinder head.



Head of Ace engine, showing Guy rotary disk valve

The claims made for this valve are that it insures better scavenging, gives a high low-speed torque, is self-cleaning and that lubrication is positive. It is said that a Guy disk valve used in an engine which was driven more than 50,000 miles showed less than 0.001 in. wear on the valve surfaces. Silent operation and freedom from warpage are other important advantages claimed.



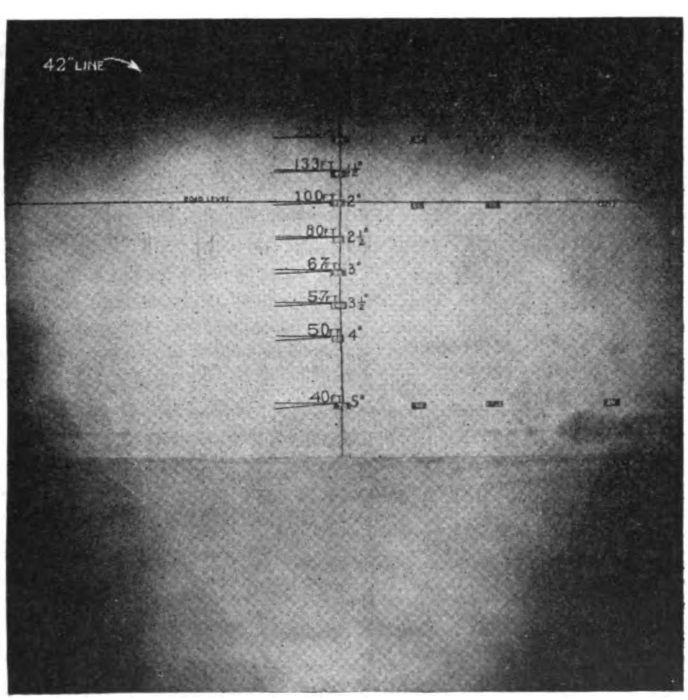
Sectional view of Guy disk valve

Devices for Controlling Headlight Glare

Specially shaped reflector designed to keep beam of light below eye level requires no special lens. Ford cars are now being regularly equipped with green visor lenses and device for focusing the bulb.

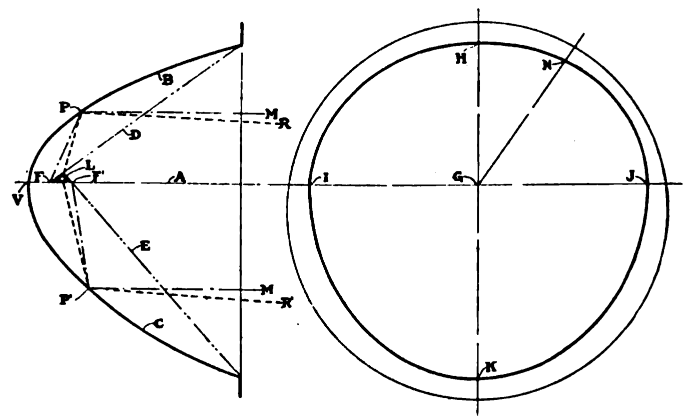
THE problem of controlling headlamp illumination so as to effect efficient lighting of the road ahead of the car and yet prevent annoyance by glare to people traveling in the opposite direction is still with us. Almost every conceivable means of attack has been made use of since the glare problem first became serious, about 1910. At first absorbing media, such as amber colored lenses, were used to quite an extent. Later came lenses of such formation as to break up or disperse the light beam, and finally it was decided that the proper principle to use was to control the direction of the beam of light, so it falls upon the road surface at a reasonable distance ahead of the car, but does not rise to a sufficient height to reach the eyes of the approaching pedestrian or vehicle driver. Use of the dispersion principle does not seem logical, for we first place behind and around the luminous source a carefully made reflector to gather the rays into a parallel beam and then place in front of the source a lens which breaks the beam up again before it has accomplished any useful purpose. The eyes of other users of the highway are always above the level of the headlights and the most logical plan seems to be to direct all the rays from the source downwardly. This can be done by use of lenses of prismatic form; it can also be done by giving the reflector a suitable shape, and this is perhaps the simplest method.

C. W. and C. H. Crockett have developed a reflector which permits of this desirable control of the beam of light. This reflector is in the form of one smooth continuous surface, but within the concavity of the reflector there is a space, in which the source of light may be placed, such that, when the light source is wholly in the space, all of the light falling on the reflector will be reflected either horizontally or in a downward direction.



Photograph of surface illuminated by beam from Crockett reflector.

The surface of the reflector is generated by revolving, about its horizontal axis, a parabolic arc whose parameter



Crockett head lamp reflector.

gradually increases as the arc is revolved through 180 deg. from its upper vertical to its lower vertical position. Referring to the drawings, the plane *GH*, through the axis *A* and on one side thereof, will cut the reflector in a parabolic arc *B*; and any other plane *GN* through the axis *A* and on one side thereof, will cut the reflector in a parabolic arc having a parameter greater than that of the arc cut by the plane *GH*; and the parameter of the section will increase as the cutting plane passes from the position *GH* to the position *GK*, where the parameter of such an axial section will have its greatest value, the corresponding section of the surface being the parabolic arc *C*. Thus the sections of the surface, made by planes through axis *A*, are parabolic arcs, all having the common axis *A* and the common vertex *V*, the focus of each arc being situated on the axis *A* between *F*, which is the focus of the parabolic arc *B* and which is the focus nearest the vertex *V*, and *F'*, which is the focus of the parabolic arc *C* and which is the focus farthest from the vertex *V*.

The sections made by planes perpendicular to the axis *A* and in the form *IHJK*, which consists of two semi-ellipses, *IHJ* and *IKJ*, having a common center *G* and a common axis *IJ*, *GH* being less than *GI*, while *GK* is greater than *GI*.

If the reflecting surface is a right parabolic cylinder, whose intersection with the vertical plane through the axis *A* is shown in the curves *B* and *C*, and if a point of light *L* is placed above the horizontal axis *A*, and in the vertical plane through *A*, and forward of the line *D* drawn from the focus *F* to a point on the parabolic arc *B* which corresponds to the upper forward edge of the reflector, none of the rays of light falling on the upper portion of the surface will be reflected in an upward direction; for, if a point of light is situated at the focus *F*, any ray *FP* will be reflected in the direction *PM* parallel to the axis, and there-

fore any ray *LP* from the light *L* will be reflected in the direction *PR*—downward. Again, if a point of light *L* is placed above the axis *A*, and in the vertical plane through *A*, and to the rear of the line *E* intersecting the focus *F′* and extending to a point on the parabolic arc *C* which corresponds to the lower forward edge of the reflector, none of the rays of light falling on the lower portion of the surface will be reflected in an upward direction; for, if a point of light is situated at the focus *F′*, any ray *F′P′* will be reflected in the direction *P′M′* parallel to the axis, and therefore any ray *LP′* from the light *L* will be reflected in the direction *P′R′*—downward. Hence, if a point of light *L* is placed above the axis, and in the vertical plane through the axis and forward of the line *D* and to the rear of the line *E*, that is, if it is placed in the shaded triangle whose base is *FF′*, none of the light falling on any portion of the surface will be reflected in an upward direction. But there will be upward reflection if any part of the source of light is outside of this triangle.

When the surface is one of double curvature, as it is in all reflectors, the direction of the reflected ray is not easily determined, but somewhat similar conclusions are true for the Crockett reflector. There is a limited space, projected in the shaded triangle bounded by the lines *D*, *E* and *A*, such that, if the source of light is contained entirely within this space, none of the rays of light will be reflected in an upward direction. But there will be some upward reflection if any part of the light source is outside of this space.

A test of this reflector was made by the Electrical Testing Laboratories of New York City using a Mazda B headlamp bulb of 18 spherical candle-power. The maximum beam candle-power was 11,000. The photographic record of this test is reproduced herewith, and it will be seen that there is no light above the 42 in. line. The reflector is said to meet the anti-glare provisions of the laws of New York, New Jersey and Massachusetts. With a reflector of this type a plain glass lens can be used, and it is believed that this reflector affords the least expensive means of dealing with the troublesome glare.

Ford Green Visor Lens

FORD cars are now coming through regularly equipped with non-glaring head lights known as the Ford green visor head lamps, installation of these head lamps having started in March. The Ford company has also placed on sale replacement lenses for the cars already in use. The new head lamp has been tested and approved in the states of Connecticut, New York, Pennsylvania, Maryland and Wisconsin, in the District of Columbia and in the city of Detroit, and tests are at present being conducted in California.

According to the Ford Motor Co., this device has been adopted in an effort to provide a head lamp which will give ample light for driving and at the same time eliminate glare.

The diagram herewith shows the illumination obtained in the New York tests and indicates that the equipment complies with both the light and anti-glare requirements. The new lamp comprises the standard Ford parabolic reflector of 1⅜ in. focal length. The lens has the upper part painted green. The visor extends ⅝ in. below the center of the lens and is tapered back to a distance of 1⅛ in. above the center line at each side. A special double filament bulb is supplied carrying a helical major filament, closely wound and 7/32 in. in length. This filament is specially focused with the filament drawn back of the focal center of the reflector until the front end of the filament is at the focus. The tip of the filament being at the focal center gives the direct beam required, while the remainder of the filament behind the center distributes light to the sides of the lamp.

Standard adjusting directions have been supplied all dealers. A shop layout for focusing and aligning the lamps is shown in the sketch herewith. The empty car is put on a level surface in front of a white wall or screen 25 ft. from the front of the head lamps. This wall must be in semi-darkness or sufficiently shielded from direct light to enable the light spots upon it from the head lamps to be clearly seen. The bright lights are turned on and the lamps focused by means of the screw at the back of the lamps, first one lamp and then the other, drawing the bulb filament slightly back of the focal center of the reflector until a semi-circular spot of light is obtained on the wall, with the flat side up and with a concentrated circular central portion. In focusing the bulb is drawn back to obtain as wide a spread as possible and still maintain the approximately flat top line and the concentrated central portion. In general, the spot of light when properly focused will measure about 5 or 6 ft. across the top.

In aligning the head lamps the brackets are bent so that the top lines of the bright spots on the wall are set at a line 28 in. above the level of the surface on which the car stands. The half cone of light from each head lamp is to extend straight forward; that is, the centers of the concentrated circular portions must be 28 in. apart. In assembling at the Ford plant, this is the last step taken before the cars leave the line.

An Analysis of Elements Which Govern Automobile Fuel Economy

Part I

A paper containing much useful information in regard to the factors which determine rolling resistance, frictional and other losses which are encountered in converting the heat in fuel burned in the engine into tractive effort at the periphery of the driving tires.

By W. S. James*

AN attempt has been made, first, to analyze and state the factors effecting the power requirements of cars; second, to analyze and state the factors affecting the amount of power supplied the car as fuel to produce at the road the power required for transportation.

The power required to propel rubber-tired vehicles over roads is delivered to the road by the wheels as thrust or tractive force which is used (*a*) to overcome wind resistance, (*b*) to overcome the resistance to the rolling of rubber-tired vehicles, (*c*) to produce linear acceleration of the car masses and angular acceleration of the wheels and (*d*) to overcome gravity deceleration when climbing hills.

The thrust or tractive force required to overcome wind resistance is proportional to the projected frontal area of the car and to the square of the velocity of the car relative to the air.

$$F = CAV^2$$

where A = area in sq. ft., C constant of proportionality, F = force in lb. and V = velocity in miles per hr.

The constant of proportionality C varies with the type of body and no reliable information seems to be available on the effect of changes in body shape on this figure. Values of C vary from 0.0030 to 0.0042 according to various authorities. The measurement of the projected frontal area of 17 different representative makes of car gave an average value of 26 sq. ft., the minimum being 24 and the maximum 30 sq. ft.

The thrust or tractive force required to overcome the road resistance to rolling of rubber-tired vehicles is nearly independent of speed (see Table 1) and depends on (*a*) the weight of the vehicle, (*b*) the character of the road surface, (*c*) the construction of the tires, (*d*) the inflation pressure of pneumatic tires and (*e*) on the type of wheel bearings. The rolling resistance of rubber-tired vehicles over different types and conditions of road surface varies widely. Values of this resistance according to various authorities run from 9 to 19 lb. per 1000 lb. of car weight on hard smooth concrete asphalt, wood or macadam, and may reach 150 to 250 lb. in sand. There is little information available as to the effect of tire construction on rolling resistance. For a given car weight the variation in road surface resistance is by far the most important item to consider in the reduction of rolling resistances.

*Associate physicist at the Bureau of Standards, Washington, D. C. Condensed from a paper presented at the Semi-Annual Meeting of the Society of Automotive Engineers.

The tractive force required to give a linear acceleration to the mass of the car and an angular acceleration to the wheels is directly proportional to the weight of the car and the weight and moment of inertia of the wheels. The force required to accelerate the wheels is about 2 to 4 per cent of the total tractive force and can be neglected.

An acceleration of from 3 to 4 ft. per sec. per sec. is usually demanded in good performance, but accelerations as high as 5 and 6 ft. per sec. per sec. are very uncomfortable for passengers. The tractive force required per 1000 lb. of car weight for several rates of acceleration, including an additional force of 3 per cent for wheel accelerations, is given in Table 2.

TABLE 2—TRACTIVE FORCE REQUIRED FOR ACCELERATION

Acceleration, ft. per sec. per sec.	Tractive Force, per 1000 Lb. of Car-Weight, lb.*
0.5	16
1.0	32
1.5	48
2.0	64
2.5	80
3.0	96
3.5	112
4.0	124

*An additional 3 per cent is assumed for wheel acceleration.

The tractive effort required to overcome grades is equal to the product of the car weight, gravity acceleration and the sine of the angle of grade. For grades less than 14 per cent the per cent grade can be used in place of the sine of the angle with an inaccuracy of only 1 per cent. In cities the grades are kept below 10 per cent unless extraordinary conditions must be met. Tractive force per 1000 lb. of car weight for grades up to 14 per cent is given in Table 3.

TABLE 3—TRACTIVE FORCE REQUIRED TO OVERCOME GRADES

The power or tractive effort required for acceleration and hill-climbing are performance requirements independent of the road surface and wind-resistance. They can be considered as one power-demand interchangeable in application as both are essential accelerations and seldom demanded at the same time. The only point of difference lies in the fact that hill-climbing does not necessarily involve wheel acceleration. This item is small and for the purposes of this illustration can be neglected.

To illustrate the relation existing between the three major power demands, wind resistance, road rolling resistance and acceleration, the characteristics of the average 1921 American car have been computed and the results are given in Table 4. It will be noticed that the tractive force available to overcome wind and road resistance and produce acceleration varies less than 4 per cent over the driving range of speeds from 10 to 35 m.p.h.; that the tractive force available to overcome rolling resistance and produce acceleration varies more than 25 per cent over the same range of speeds; and further that grades of from 9 to 4.5 per cent can be negotiated at speeds from 20 to 35 m.p.h., dependent on the road resistance to rolling. If the car characteristics chosen are representative of the present American product meeting the demands of the driving public, the performance demands of the public are in no way unreasonable with our roads as they are to-day.

Fuel conservation from the point of view of power demands of the car would be greatly furthered by a sound, far-sighted good roads program. The power demands to overcome grade and high average rolling resistance would not only be reduced but, more important still, car weights could be reduced without any sacrifice of constructional sturdiness. Any reduction in car weight means an almost proportionate decrease in the power required and therefore in the fuel to supply the power.

The processes involved in the production of power at the rear wheel rims from fuel supplied the engine may be divided into four main groups; (*a*) the preparation of an explosive mixture of fuel and air, (*b*) the transformation of the chemical energy latent in the explosive mixture into gas pressure, (*c*) the transformation of the gas pressure produced into crankshaft torque and (*d*) the transformation of crankshaft torque to thrust at the road surface.

The preparation of an explosive mixture of air and fuel involves three major factors; (*a*) proportioning the proper weight of air to a given quantity of fuel, (*b*) mixing the fuel and air as intimately as possible, and (*c*) controlling the weight of combustible mixture used in a unit of time.

In proportioning the air and fuel it is important to know the limiting values of the ratios of weight of air to weight of fuel which will explode under cylinder conditions. There are some data available on this subject but they are inadequate.

[1]The data used in this computation were a maximum of 33 hp. at 2270 r.p.m.; a transmission and rear-axle efficiency of 85 per cent; the torque-speed curve was proportional to that given in a paper by A. L. Nelson, published in AUTOMOTIVE INDUSTRIES for Jan. 27, 1921; 32-in. tires; a rear-axle ratio of 4.42 to 1; a car-weight of 3096 lb. without any load and a passenger weight of 750 lb.

[2]Projected frontal area of car 26 sq. ft. The division of the total car resistance by the car-weight does not mean that the air-resistance varies with the car-weight. It was done for ease of comparison with the available thrust and road-resistance for 1000 lb. of car-weight.

[3]Ten pounds tractive force per 1000 lb. of car-weight is nearly equivalent to the tractive force required to move 1000 lb. up a 1 per cent grade.

In an engine cylinder the explosive charge is diluted by the products of combustion from the previous working stroke. At the end of the exhaust stroke there remains in the clearance volume an almost constant weight of exhaust gas irrespective of the engine speed and load. As the weight of unburned charge taken in decreases with any decrease in the load, the percentage of exhaust gas dilution increases. The effect of inert gas dilution on explosive range of gasoline-air mixtures has not been extensively investigated. Fig. 1 is drawn from admittedly meager data on this subject. It indicates that the less the stratification or the greater the turbulence of the cylinder contents, the richer the leanest mixture which will fire regularly must be. From the viewpoint of fuel economy, the lean explosive limit of the mixture of air, fuel and exhaust gases in the cylinder at ignition sets a maximum limit of leanness and, therefore, thermal efficiency unless charge "stratification" is resorted to.

Within the explosive proportion limits there are two mixture proportions which are interesting from the point of view of internal combustion engines and one from an academic viewpoint. These are (*a*) maximum economy mixtures, (*b*) maximum power mixtures and (*c*) chemically "correct" mixtures. Excellent experimental work has been done by several observers on maximum economy mixtures, and it is concluded that the mixture for maximum economy is the leanest mixture on which the engine will fire regularly, usually about 16 to 1. Mixture ratios for maximum power development have also been carefully studied, and found to be practically independent of speed and load and to vary from 11 to 1 to 13 to 1.

Effect of Mixture Proportions

If equal proportions of each of the 10 compounds of the paraffin series be mixed in a single fuel and chemically correct mixture ratio of the average would be incorrect for the lightest or heaviest component by only 1.2 per cent. Similarly such a mixture for the aromatics would be incorrect by 3.5 per cent, for the acetylenes 1.3 per cent and always correct for the olefines.

It will be noticed that the maximum economy mixtures are leaner and the maximum power mixtures are richer than the chemically correct mixtures. The presence of exhaust gases, the law of mass action and the limited time available for the completion of the reaction would explain why all three mixtures are not the same. At the present time our knowledge of the relations between these factors is insufficient. In a cylinder of fixed dimensions, as the oxygen occupies a greater volume than the fuel vapor it must be entirely consumed to obtain the maximum power. To accomplish this in the shortest possible time an excess of vapor must be present. In the same way when all the fuel is to be consumed as in the case of maximum economy mixtures, excess air must be present.

To indicate what the variation in the mixture ratio with changes in the speed and the load is with present carbureters, several makes of stock carbureters, representing at least 60 per cent of the total number of carbureters in use to-day, have been tested in the carbureter test plant at the Bureau of Standards. The results show that there is little agreement among carbureter manufacturers as to the variation of mixture ratio requirements with changing loads and speeds.

The average mixture ratio, computed from exhaust gas analysis, supplied the engines of 23 average cars tested under winter conditions by the Bureau of Mines,* varied from 12 to 13.5, corresponding more nearly to maximum power than maximum economy.

*See Gasoline Losses Due to Incomplete Combustion in Motor Vehicles, by A. C. Fieldner, A. A. Straub and G. W. Jones, published in *Journal of Industrial and Engineering Chemistry*, vol. 13, p. 51.

Mixing and Vaporization

Insuffcient fuel and air mixing is probably the source of the greatest fuel waste to-day. Poor distribution among cylinders and the need for over-rich mixtures when starting and accelerations are the result of insufficient mixing. Minute and thorough subdivision of the fuel is the solution of the mixing problem. The difficulties involved in attaining thorough mixing are realized when it is appreciated that (*a*) when liquid gasoline is injected into an airstream probably not more than a small percentage is ever vaporized before entering the engine cylinder except when the air in the manifold is heated; (*b*) a cube of liquid gasoline 0.1 in. on a side is all that is required to be mixed with a cube of air 2.1 in. on a side; (*c*) when the cube of gasoline is evaporated the vapor occupies a cube 0.6 in. on a side; and (*d*) from 0.1 to 1.0 sec. elapses from the time the liquid fuel leaves the carbureter jet until it is ignited within the cylinder. Subdivision of the fuel may be accomplished in two ways, (*a*) by vaporization or change in state, and (*b*) by minute subdivision of the liquid or atomization.

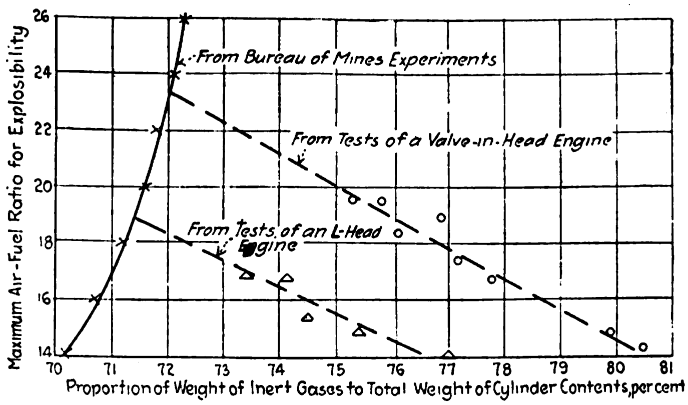

Fig. 1—Effect of an increase in the weight of the inlet gases on the maximum air-fuel ratio for explosibility.

Vaporization of the liquid fuel gives the most minute subdivision attainable. To vaporize the fuel a definite quantity of heat must be supplied per pound. The latent heat of vaporization and specific heats of the liquid for gasolines and some pure compounds found in liquid fuels are given in the series of articles by Ricardo published in recent issues of AUTOMOTIVE INDUSTRIES. Variation in the latent heat values are to be expected from the known variation in the composition of gasolines. Vaporized fuel occupies over 200 times the volume of the liquid fuel before vaporization, and in an explosive mixture the vapor volume represents from 1 to 2.5 per cent of the total volume of the charge.

Complete vaporization of the fuel would decrease the volume of air which could be admitted to a fixed cylinder; hence, the power of the engine by about 2 per cent. On the other hand, the cooling of the charge caused by such evaporation, if no heat were supplied the air from external sources, would contract the air by some 7 per cent, thus increasing the power output by this amount. Thus vaporization of the fuel causes a net increase in the power output, and the heating of the charge in the manifold, a decrease. The temperature required for complete vaporization is at least equal to the temperature at which the vapor pressure of the fuel equals its partial pressure in the explosive mixture. If this is more than about 20 deg. Fahr. above that of the entering air, a net loss of air volume will result.

Sufficiently fine atomization of the liquid fuel at the carbureter jet and subsequent vaporization within the cylinder during compression would accomplish the same

result as vaporization without the attendant loss of air volume and power output.

Charge Quantity Control

Three methods have been used to control the quantity of explosive charge used, namely, reducing (*a*) the manifold pressure but not the volume of the charge drawn from it which is the usual throttle control; (*b*) the effective time interval of inlet valve opening; but not the manifold pressure or what is known as variable inlet valve timing; and (*c*) the weight of the *combustible* charge but not the cylinder charge weight or the stratification and direct fuel injection method. In the first method the power required to pump the cylinder charge from the manifold to the exhaust pressure increases with a reduced load, thus reducing the economy with the load. At 20 per cent full load the loss in economy may amount to about 20 per cent. Exhaust gas dilution also increases with a reduction in the load and thus reduces the leanness of the mixtures which will explode. When variable inlet valve timing is used there is no increase in the "pumping loss" with a reduction in the load, and the exhaust gas dilution increases with a reduction in the load in the same manner as when charge throttling is used. However, mechanical complications are introduced. Results on a test of an engine using a late closing inlet valve show that at a little less than half load the fuel consumption was about 50 per cent less than that attained when using fixed valve timing and the usual throttle control. In the case where charge stratification is relied on entirely, "pumping loss" is entirely eliminated. As yet no commercial application of direct injection engines has been made to automobiles. Mr. Ricardo gives results from tests of an engine using stratified charge and fuel throttling for reduced loads. The results show a remarkably constant thermal efficiency of from 30 to 35 per cent from full load to about 0.15 load.

The chemical energy of the explosive mixture supplied the cylinder is transformed into gas pressure by (*a*) an increase in temperature of the gases within the cylinder resulting from heat added during combustion and (*b*) a difference in specific volume of the gases before and after combustion, due to a change in the number of molecules during combustion.

The voltage necessary to produce an ignition spark varies from about 2000 to 15,000 volts, increasing with increase in density of the charge and length of spark gap at constant temperatures of the electrodes. Recently it has been found that an increase in the temperature of the spark plug electrodes decreases materially the sparking voltage required. This decrease may amount to as much as 50 per cent. It has been shown that when a truly explosive charge surrounds the spark gap any spark passing the gap will ignite the charge. It has not been shown, however, that this is true if the explosive charge be near the limit of inflammability, from either incomplete vaporization or dilution. The results of the experiments on the explosive limits of mixtures indicate that the character of the spark discharge has a decided effect on ignition. The effect of spark characteristics on the ignition of poor mixtures needs further attention.

Mention should be made of "spontaneous" or "autoignition" temperatures. Spontaneous ignition temperature is usually thought of as the temperature at which a given mixture ignites without ignition being supplied at any point from an outside source. Spontaneous ignition may occur in an engine cylinder with certain fuels and compression ratios. When an engine is operating certain metal parts, such as spark splug electrodes and valves, or carbon deposits, remain at a higher temperature than the average temperature of the charge. If the temperature of any of these surfaces is sufficiently above the ignition point of the fuel so that it can supply enough heat to raise a portion of the charge to the spontaneous ignition temperature, ignition will take place even though the average temperature of the gas is below its spontaneous ignition temperature. The lower the ignition temperature of the gas, the smaller the rise in temperature necessary to be produced in this way. Hence, ignition of this sort will occur in the engine at average mixture temperatures lower than the spontaneous ignition temperatures of the fuel, but these average mixture temperatures will vary under the same cylinder conditions with different fuels in much the same manner as the true spontaneous ignition temperatures of the fuels. It has been shown that the spontaneous ignition temperature for hydrogen at least is materially raised by the dilution of the explosive mixture by an inert gas.

Assuming the usual pressure volume and temperature relations, the increase in the average gas temperature, and therefore the cylinder pressure, is limited by four factors, (*a*) the amount of heat liberated by the combustion of the fuel per unit volume of combustible mixture, allowing for heat absorbed in the dissociation of the products of the combustion, (*b*) the heat capacity of the gases contained in the cylinder at the end of the preceding exhaust stroke, (*c*) the rate of heat loss from the hot gases, and (*d*) the rate at which the mixture burns.

Heat of Combustion

The heats of combustion of nearly all of the constituents of gasoline have been measured. (Some values for these heats of combustion were given in the article by Ricardo printed in AUTOMOTIVE INDUSTRIES for April 14, 1921.)

The rate of heat loss from the gases during combustion to the cylinder walls is not known. It is probably very high but of short duration. Measurements of the amount of heat entering the jacket water are of little value for this purpose. There is very little reliable information on the rate at which energy is liberated from a combustible mixture. This rate is not necessarily that with which the flame passes through a mixture.

The number of factors believed to affect the rate of burning is large, probably because we know so little about it and cannot as yet separate the important from the unimportant factors. Some of these will be enumerated but not discussed because of lack of information. They are (*a*) temperature and pressure at ignition, (*b*) point of stroke at which ignition occurs, (*c*) number of points of ignition, (*d*) mixture ratio, (*e*) shape of combustion chamber, (*f*) fuel, (*g*) turbulence, (*h*) auto-ignition temperature of fuel and (*i*) detonation tendency.

The cylinder pressures after combustion will be increased by an amount proportional to the increase in specific volume of the gears. This increase in pressure due to the presence of a greater number of molecules increases with the molecular weight of the fuel.

Gas Pressure Transformation Loss

The transformation of gas pressures into crankshaft torque in a cylinder, reciprocating piston and crank mechanism is fundamentally an intermittent process. It is made continuous either by the use of a reservoir of energy such as a flywheel or by the multiplication of elements acting intermittently, that is, the addition of working cylinders. There are four sources of loss in this mechanism: (*a*) incomplete expansion, (*b*) heat transfer from the gases under pressure, (*c*) work of filling and exhausting the cylinder and (*d*) mechanical friction of the moving parts. The loss from incomplete expansion is

usually given in terms of air as a working fluid and is one minus the so-called air cycle efficiency. The usual computation of the air cycle efficiency involves the assumptions that (*a*) the last three sources of loss mentioned earlier in this paragraph are zero, (*b*) the combustion is instantaneous, (*c*) the specific heat at constant volume is independent of both temperature and pressure, (*d*) the specific volume of the working fluid after combustion is the same as it is before combustion, (*e*) the ratio of specific heats of the unburned charge is the same as that for the burned charge and both are independent of temperature and pressure and (*f*) there is no dissociation of the products of combustion. Any loss incurred through incomplete expansion is directly due to the imperfection of the mechanism, because it is impracticable to increase the expansion without an excessive increase in the weight and size of the engine. This loss, however, should not be altered by the losses or gains resulting from the last five assumptions just made, nor should it be altered by assuming constants for a working fluid other than that which it is actually possible to use. Losses or gains due to these assumptions should be charged to the fuel and working fluid used. To be sure, our present knowledge of the effect of these assumptions is incomplete, but it is sufficient to tell us that none of them is negligible. The relationships involved in each can and should be determined in order that the status of any process of combustion under pressure can be truly interpreted. Some recent preliminary determinations of the ratio of specific heats at atmospheric temperature and pressure of a particular sample of explosive mixture taken from an engine, gave a value of 1.36 and a particular sample of exhaust gas gave 1.34. Corrections for the higher temperatures of the exhaust gases would probably reduce the latter figure below 1.30.

The loss due to the heat transferred from the working fluid to the cylinder walls is directly chargeable to the type of mechanism used. No good values of this loss have been determined but they may range from 15 to 25 per cent of the total heat in the fuel. The work lost in filling and exhausting the cylinder includes (*a*) a direst loss, negative piston pressures as given by the lower loop of the indicator card, and (*b*) an indirect loss, the loss in the weight of the cylinder charge due to throttling, gas heating, etc., usually included under the term volumetric efficiency, which is one of the factors governing the size of the engine used to give a definite performance, or the maximum power output of a given engine. Any reduction in the maximum power with a constant mechanical loss involves a loss in brake efficiency, and if a larger engine is required to produce the same power, both the mechanical losses and the power required to carry the engine are increased as the size of the engine is increased. The losses due to negative piston pressures increase with reduction in load. Losses due to a reduction of the cylinder charge vary with valve timing, valve design and engine speed. They may vary from 50 to less than 5 per cent. The losses due to mechanical friction of the moving parts vary from 10 to 40 per cent with different engines and increase so materially with speed as to raise some doubt as to the possible fuel economy of small high speed engines.

Power Transmission Efficiency

The transformation of crankshaft torque into thrust at the rear wheels involves three factors; (*a*) transmission efficiency, (*b*) universal-joint efficiency, and (*c*) rear-end efficiency. All of these factors are affected to a marked degree by the kind of lubricant used and its method of application.

Considering the system as a unit the efficiencies may vary from 50 to 85 per cent according to Riedler. The value given by the Automobile Engineer's Handbook, 1920, London, is 85 per cent. Lewis P. Kalb considers 90 per cent to be a closer value. Universal joint efficiencies, according to C. W. Spicer, range from about 92 to nearly 100 per cent when transmitting power in excess of 5 hp. At lower powers the efficiency may drop as low as 80 per cent. These data include results with angles of from 2 to 12 deg. with forks in the same plane and at 90 deg. Mr. Spicer makes the following statement:

> Between 10 and 100 per cent of full load, the efficiency is above 99 per cent for all angles less than 7 deg.

The efficiency of the gearbox according to tests made by Worby Beaumont is from 70 to 90 per cent on direct drive. C. M. Allen finds that the efficiency of a worm gear axle varies from 70 to 85 per cent with power inputs of from 2 to 8 hp. reaching 90 per cent for higher inputs. With a bevel gear axle the efficiencies ranged from 95 to 98 per cent with inputs of from 2 to 8 hp. and were above 98 per cent for higher inputs.

From the point of view of the power requirements of cars it is believed that (*a*) the car performance demanded by the average driver is not unreasonable and (*b*) greater fuel economy could be attained by a sound far-sighted good roads program through possible reduction of car weight and also road resistance.

From the point of view of power development and its delivery to the road it is believed that (*a*) the greatest gain in fuel economy would result from an effort spent on the preparation of the unburned charge under all conditions of temperature, engine speed and load, first from a thorough mixing of the air and fuel and second from a correct variation of the fuel and air proportions; (*b*) the reduction of the mechanical friction losses, possibly through a change of engine speed and size, will increase the fuel economy at part throttle without any sacrifice in performance and (*c*) the closer study of the processes of combustion will make possible a rational basis for the statement of the ultimate engine efficiency and a clearer conception of the value of different fuels.

Some of the most valuable information presented in this paper was contained in six appendices written by other members of the Bureau of Standards staff. These will be published in condensed form in a later issue.

The New Federal Is Heavier

(*Continued from page* 1196)

with a ratio of 10¼ to 1 as standard. The standard tire equipment comprises 36 by 6 front, and 40 by 6 dual rear, solid tires. Forty by 12-in. giant pneumatics can be provided at extra price. The wheels are steel, with hollow cast spokes, but webbed internally for strength. Among the items of standard equipment are towing or pintle hooks at the front of the frame; a hub-odometer and Alemite greasing attachments on all bearings.

A LONDON-AMSTERDAM aerial service was started on April 14 by the Koninklijke Luchtvaart Maatschappij with a Fokker Type F-111 monoplane. The machine is fitted with 230-hp. Siddeley-Puma engines and has a cabin seating five passengers, of which three face forward and two aft. The driver's seat is at the side of the engine, much like in the latest type of London motor bus. The first regular trip started from London at 10:15 a. m. and ended at Amsterdam at 2 p. m. the same day. A quarter of an hour after the arrival of the first machine in Amsterdam the second machine left the latter city for Croydon, where it arrived at 6 p. m.

How to Lighten Front Axle Sections Without Decreasing Strength

Narrower outside draft angle is entirely practicable and permits better disposition of metal. In one case slight changes in section made possible a saving of over 6 lbs. per axle without material decrease in strength.

By Herbert S. Jandus

IN the past, the design of front axle sections was arrived at by the rule of "present practice." The usual procedure was to collect all possible data on current designs which had been in service for a period of time, make such changes as the record indicated, check up the section modulus and let it go at that.

Of course experience is fundamentally the biggest factor in successful design, but for economical reasons it is advisable to combine that experience with a reasonable amount of theoretical practice and check the results obtained so as to determine whether the section is the most suitable and economical one that could be devised.

Obviously the most economical section is that having the bulk of its area disposed at the greatest practicable distance from the neutral axis of the section. Structural rolled I-beam shapes represent, perhaps, the most economical sections in use to-day. The outside of their flanges being flat and without draft, and only a slight draft being necessary on the inside of the flanges, the resulting section is one in which the metal is advantageously placed for minimum area and maximum strength.

While it is possible and practicable to roll sections with thin webs and flat flanges, it is not practicable to forge them thus. On forgings draft is necessary both on the outside and the inside of the flanges, and the thickness of metal cannot be reduced beyond the point at which the metal will readily flow to the required depth in the die. It is, however, both possible and practicable to improve considerably on the present average design and for a given strength increase the "efficiency" as defined below from 5 to 10 per cent.

The usual draft angle for forged axle sections is 10 deg., this angle being advocated by the forge shops as best adapted to quantity production, as it obviates sticking in the dies due to the contraction of the forging in the die-block. Since the contraction of the forging in cooling is responsible for this difficulty, it is apparent that the inside faces of the flanges are the surfaces that tend to grip the die-block, while the outside faces tend to draw away from the die.

It seems, therefore, that a reduction of the draft angle on the outside of the flange would not only be practicable from the forging standpoint but would result in a more advantageous disposition of the metal of the section. Upon taking this matter up with the forge shops it was found that 7 deg. was a perfectly practicable draft angle for the outside of the flange and even 5 deg. could be used without difficulty.

Figs. 1, 2, and 3 show axle sections having outside draft angles of 10, 7 and 5 deg. respectively, while Fig. 4 represents an ideal condition with no outside draft. Taking Fig. 4 as an arbitrary standard for comparison and calling it 100 per cent, the "efficiencies" of Figs. 1, 2 and 3 are 93.4 per cent, 95.3 per cent and 96.8 per cent respectively, these "efficiency" values being based on the ratio of the radius of gyration to one-half the total depth of the section. The inside draft angle of the above sections is 10 deg. in all cases.

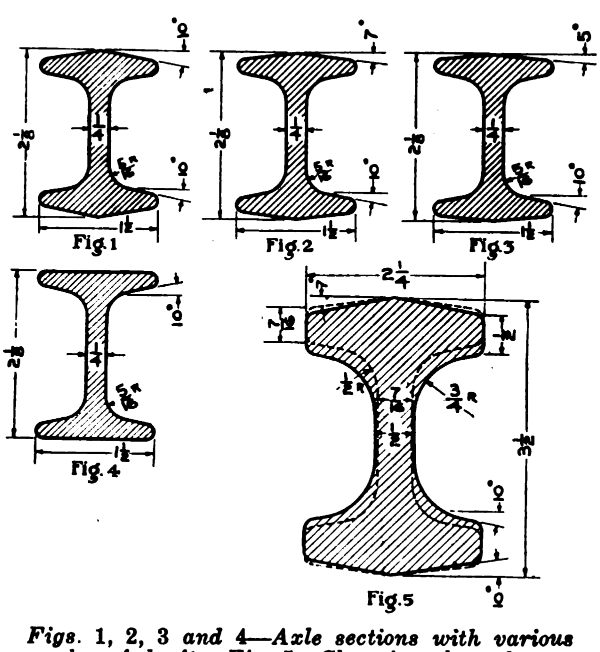
Since the strength of any section varies directly as the cube of its depth while the area varies directly as the first power of the depth, it is evident that the ratio of the moment of inertia to the area would not represent a constant ratio for different sizes and shapes of sections. In order to allow for this variation and express a true relation of strength to area which is independent of the size or shape of section under consideration, it is necessary to use a first power function of the moment of inertia. The radius of gyration fulfills this requirement as follows:

$$r \text{ (radius of gyration)} = \sqrt{\frac{I}{A}}$$

in which

I = moment of inertia,
A = area of section.

Now I is a function of the fourth degree while A is a function of the second degree. The radius of gyration, therefore, is a first power function and represents a distance from the neutral axis at which the total area of the section may be considered as concentrated. It follows that for sections of the same area regardless of shape, that one having the greatest radius of gyration has the greatest "efficiency," or to put the expression in another form, the more closely the radius of gyration approximates the distance of the outermost fiber from the neutral axis, the



Figs. 1, 2, 3 and 4—Axle sections with various angles of draft. Fig. 5—Changing the axle section shown in heavy lines to conform to dotted lines decreased axle weight 6¾ lb. without material decrease in strength

more "efficient" the section.

The ratio of the radius of gyration to one-half the depth of the section may be designated the "efficiency factor," and represented by the symbol e, thus:

$$e = \frac{r}{d}$$

The values of e for the different sections shown are as follows:

Fig. 1—10 degrees draft—$e = .700$
Fig. 2— 7 degrees draft—$e = .715$
Fig. 3— 5 degrees draft—$e = .726$
Fig. 4— 0 degrees draft—$e = .750$

In order to show a practical application of the above principles as applied to an actual axle section, attention is directed to Fig. 5. This section is one in actual use to-day and has a 10 deg. outside and inside flange draft. The properties of this section are as follows:

$I = 5.830$
$A = 4.350$ sq.in.
$r = 1.157$
$e = .661$

The "efficiency factor" value of .661 corresponds to an "efficiency" of 88.7 per cent based on the arbitrary standard section above referred to.

The dotted outlines in Fig. 5 indicate a substitute trial section having a 7 deg. outside draft and a flange and web thickness of 7/16 in. instead of ½ in. as in the original. The properties of this revised section are as follows:

$I = 5.760$
$A = 3.776$
$r = 1.234$
$e = .706$

This value of e corresponds to a relative "efficiency" of 94.75 per cent and represents a gain of 6 per cent. It should be noted that the above revised dimensions were held within the limits prescribed by the original section and this necessarily limits the possible increase in efficiency. An increase in the width of the flanges would, of course, place more metal away from the neutral axis with a corresponding gain in "efficiency."

In the particular case above cited, the axle bed is approximately 43 in. long from outside to outside of the spring pads. The saving in area is .574 sq. in. or, for the total length above named, 24.1 cu. in. At 0.28 lb. per cu. in. of steel, this corresponds to a saving in weight per axle bed of 6¾ lb., an item of no small importance when large production costs are considered.

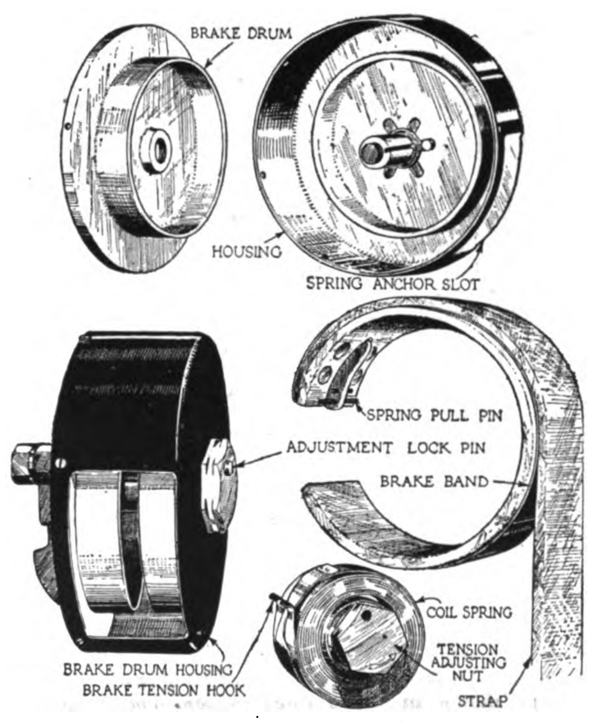
By the observance of the above principles and a little care in the design and proportions of an axle section it is possible to produce practical sections having a relative "efficiency" as high as 97.0 per cent.

A New Type of Shock Absorber

A NEW type of shock absorber in which the resistance to spring action at the normal position of the spring is very slight and which increases as the spring deflection increases, has been put out by the Watson Company. The new shock absorber known as the stabilator depends on friction for its operation, the friction being secured between a brake band and shoe, which is so mounted and designed as to afford varying degrees of friction, depending on the location of the spring.

The illustration herewith shows the parts of the shock absorber. The brake drum and housing are stationary. Surrounding the drum is a brake band, around part of the circumference of which is a pull strap which is connected with the axle members. The tension on the brake band is regulated by a coil spring which is held at its inner end by a slot in the hub of the shock absorber. At the outer end there is a hook which engages with the end of the brake shoe. As the spring takes up its normal position under the ordinary load of the car, the brake band is unwrapped from the shoe to such a position that very little friction occurs, because of the fact that there is only slight engagement between the brake band and shoe. This unwrapping is done against the tension of the spring. When an obstruction in the road is struck, causing the axle to lift off the ground, the spring tension causes the brake band to warp around the drum just as rapidly as the pull on the strap is released, due to the flexure of the spring. The friction between the band and drum prevents the rapid rebound which would ordinarily occur, due to the potential energy in the leaf spring. As a result, the spring is allowed to return slowly to normal position, the resistance to its action tapering off gradually, as the amount of contact between the brake band and drum decreases.

Due to the length of the coil spring, no flexure of the leaf spring is so rapid that the movement of the brake band cannot keep pace with it. The result is that the shock absorber is ready to function on the instant that the spring tends to return to normal. Due to the wrapping action of the brake band around the drum, which increases with the amount of spring flexure, the action of the shock absorber is practically proportional to the action of the leaf spring. The tension of the spring is adjustable by turning a nut on the outside of the housing, thus winding the spring more tightly, or releasing it to some extent. All of the parts are given a Parker rustproof finish and the brake band material is a special quality designed to endure the life of the car.



Parts of the Watson "stabilator"

Fifty million citizens are made happier, healthier and better by the automobile.

Can you imagine a city without automobiles? Think about it.

Material Flows Steadily With Efficient Intra-Plant Trucking

An analysis of trucking methods in any plant may reveal opportunity for reducing costs and eliminating interruptions from the flow of material. In the big factory discussed here, practically no hand trucking is necessary. Planning and supervision achieve the results described.

By Norman G. Shidle

TO operate a plant comprising nearly a million and a half square feet of active working space, and to move all the material required for this task without the use of a hand truck is a notable achievement in the design and operation of production equipment and methods. Theoretically this has been accomplished at the Studebaker light six factory; practically it has been so nearly accomplished as to render the achievement no less noteworthy.

The elimination of hand trucking means not only reduced labor costs,. but also the reduction of confusion to a minimum, the lessening of delays and interruptions, and a continuously high standard of efficiency in the handling of material. Two factors are responsible for the accomplishment of this end.

1. The layout of buildings and equipment, together with the installation of conveyors and other mechanical labor-saving equipment in every possible instance.
2. The effective routing and handling of power-trucking equipment.

The degree to which the first factor is developed will determine to a large extent the difficulty of handling the second. But even under the best conditions, a great deal of careful planning and intelligent administration is necessary to get the best results from a minimum of trucking equipment.

The completeness of the conveyor and labor saving equipment and the efficient way in which it has been placed and utilized at this plant cannot be adequately treated in a brief article. In making all the parts for and assembling a large number of cars each day, however, it is obvious that there must be a movement of material between buildings and sections that cannot be handled in any way except by trucking. And it is apparent that the continuous flow of material through the various departments is dependent fundamentally upon the efficiency of the trucking system. In fact, the very completeness of the conveyor equipment within the various departments renders more necessary than ever an efficient trucking system, since a break in the flow of material means that much expensive equipment is idle.

Moreover, the problem cannot be solved simply by a multiplicity of trucks of various kinds. The larger the number of trucks and operators or laborers, the greater the need for supervision and direction, the greater the chance for confusion and inaccuracies and the greater the investment in trucking labor and equipment. In other words, the only solution to the problem lies in applying to the matter of intra-plant transportation the same methods of careful analysis, intelligent routing, and close supervision that are exercised in connection with other phases of the production system.

There are more opportunities for waste in an inefficient trucking system than are generally realized. Some of these have been pointed out. A description of the trucking methods used at this Studebaker plant serve to show how trucking costs can be reduced through intel-

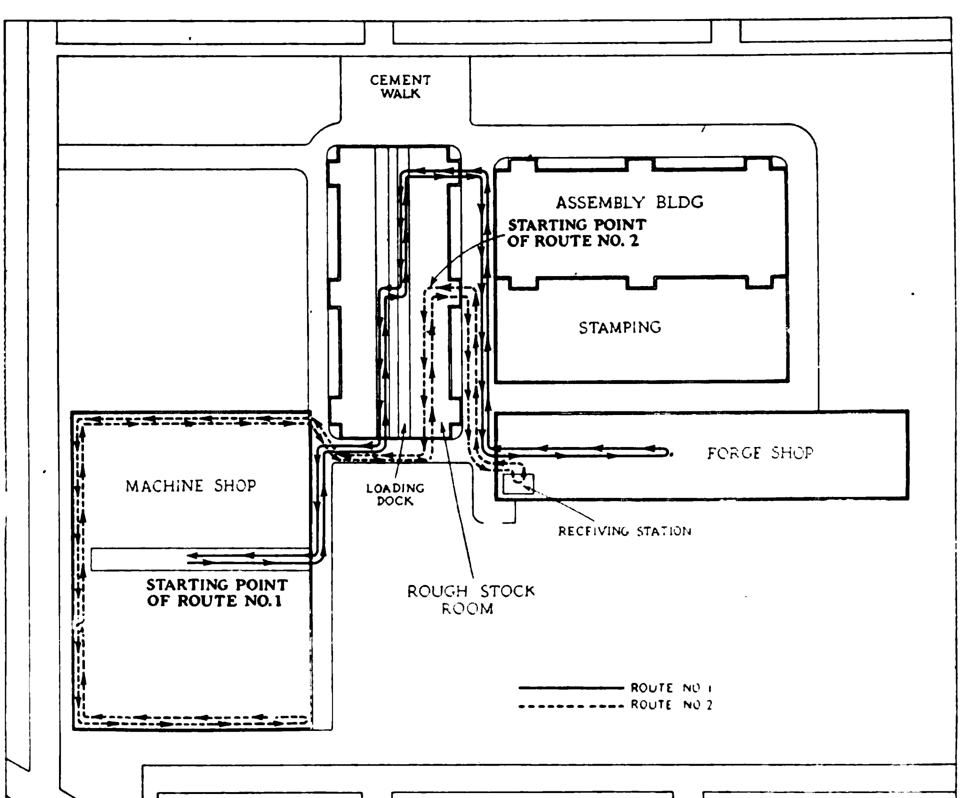


Fig. 1. Ground plan of Studebaker light six plant, showing relative position of various buildings, together with truck routes

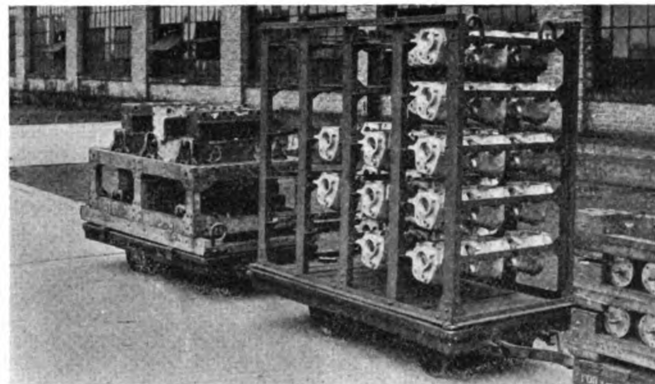

Fig. 2 (Above)—Type of special trucks used for carrying transmissions and cylinders
Fig. 3 (Below)—Type of special truck used for carrying crankshafts

ligent planning and routing, and how important is this phase of production activity.

All of the parts of this car are manufactured within the limits of the plant, with the exception of the foundry work, which is located at some distance away. The accompanying plan, Fig. 1, shows clearly the various units of manufacture and their relative location. On the basis of this plan it is possible to discuss definitely the various aspects of the trucking system. Samples of these special trucks are shown in Figs. 2 and 3. Fig. 2 shows the type of truck used for carrying transmissions and the type used for cylinders, while the crankshaft truck is shown in Fig. 3.

As stated previously, there is practically no hand trucking done in the plant. The equipment for moving material from one department to another consists of several Mercury electric industrial trucks and a large number of small box trucks and special built trucks or racks for specific parts. The box and special trucks are hauled in trains by the Mercurys, each Mercury having a special route and a definite task to perform.

Run Number 1 and Run Number 2 operate on a schedule as do railroad trains, making certain definite stops at definite times, and for a definite purpose. Run Number 1 begins at the machine shop inspection bay, as indicated on the drawing. It should be explained in passing that the finished production of the machine shop feeds directly into this inspection bay from both sides. Here the finished machined parts are inspected and loaded on the box and special trucks. The trucks are then made up in trains.

The Mercury comes to the inspection bay, hitches on to this train of finished parts and carries it out of the inspection bay along the route traced on the map to the shipping and receiving dock which bisects the sub-assembly building. Various platforms protruding from the different floors are adjacent to the various sub-assembly stock rooms, in which are stored the finished parts for sub-assemblies.

At this receiving dock the Mercury drops from its train the trucks filled with finished parts ready for the sub-assemblies. The big traveling crane then picks up the trucks and distributes them to the proper platforms.

From here the Mercury train goes on to the assembly building where it drops more trucks. The trucks contain certain parts which go directly from the machine shop to the final assembly line. From this point the train goes on to the forge shop where it makes its last stop. Here it drops the finished parts which are to be heat treated.

Having left the last of its full trucks, the Mercury picks up the empty forge shop trucks, and starts on the return trip, picking up empties at the various stopping points of the backward journey. The entire round-trip for this run comprises a distance of about .7 of a mile. The Mercury train runs on a thirty-minute schedule, leaving the machine shop inspection bay every thirty minutes throughout the day. A view of Run Number 1 Mercury train leaving the machine shop inspection bay is shown in Fig. 4.

The driver punches a time clock at the beginning of each trip, the first trip being at 7:15 a.m., according to the usual schedule. An examination of a number of time cards picked at random from this run indicate that it has proved possible to adhere to the schedule with surprising regularity. Everyone with any actual experience in attempting to regulate similar trucks, realizes the many petty delays and difficulties which tend to throw the schedule out.

A careful planning of the route, however, together with thorough instructions to the drivers concerning their duties and routine, has made it possible here to eliminate a large proportion of these inefficiencies. The trains are made up for the driver at each station, so that he has to leave the truck only to attach the train to the Mercury. As an indication of how well it has been possible to work out this system, the following times are given from a time card of the driver on this run. The card was chosen at random, only the times for the afternoon runs are given, but will be sufficient to illustrate the point:

P. M.: 0.18, 0.90, 1.40, 1.72, 2.20, 2.67, 3.17, 3.65, 4.13, 4.65.

Run Number 2 is the longest, requiring 50 minutes to complete a round trip. Not only is this run of considerable length, but it includes a number of stopping points.

The run begins in the rough stock room, where the Mercury starts out with a train of trucks loaded with rough stock destined for the forge shop. It carries this train to the forge shop, drops it, and brings back finished forgings to the rough stock room. It then takes a train of rough stock parts to the machine shop, by the route indicated on the drawing.

As it enters the machine shop at the end nearest the sub-assembly building, the Mercury drops off its train at an inspection desk, where all of the parts are counted. While this load of rough parts is being counted and inspected, the Mercury picks up the train which it brought on the previous trip and which has subsequently been counted. This it takes around the outside aisle of the machine shop, dropping off at each of the various departments, the rough parts which are to be machined there.

The machine shop is so arranged that with one or two exceptions, the first operation on every part is done on a machine adjacent to this outside aisle. Thus no hand trucking is necessary to bring the stock to the machine. The Mercury simply drops the truck load and the stock is practically in position for the operator to take the pieces and place them in the machine for the first operation.

When the Mercury has thus disposed of all of its train, it turns in its tracks, and picks up empties on the way back. It carries this load of empties back to the rough stock department and is ready to begin another round trip.

It will be noted, as indicated previously, that the machining operations are so arranged that the last operation on each piece feeds into the machine shop inspection bay, out of which the finished parts are carried by the Mercury on Run Number 1 as described. Thus with the first operation placed so as to receive the parts directly from the Mer-

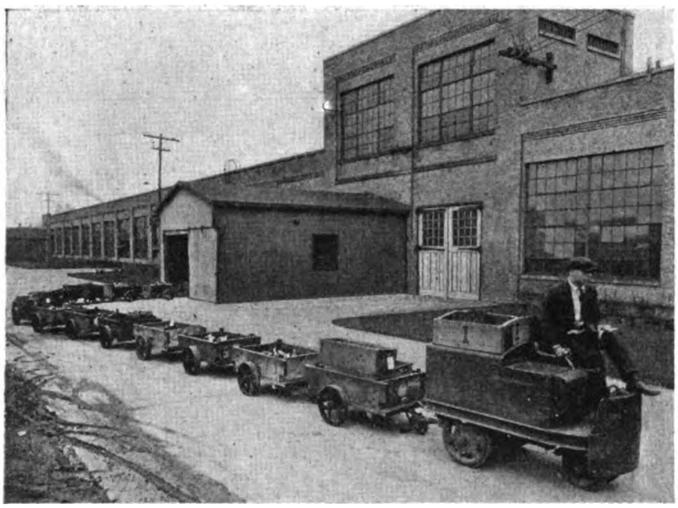

Fig. 4. Truck train leaving machine shop receiving bay on Run Number 1

cury on Run Number 2, no hand trucking or manual labor of that kind is necessary.

The driver on this Number 2 run also punches a time clock, 50 minutes being the time required for a round trip, as stated before. In this case, however, he punches a clock at several points on his journey. Fig. 5 shows the card used for this purpose, the points at which he checks himself, and the times of the trips for one morning.

Run Number 3 is not operated on a definite time schedule, but the driver has a set program which must be followed out. The program is such that it is impossible for him to have any idle time, though the run is such that a time schedule is not feasible.

This driver operates on the second, third, and fourth floors of the sub-assembly building and on the second floor of the final assembly building. The various sub-assemblies, including front and rear axle, transmission, wiring and small parts, motor, etc., are concentrated in the one building, which is connected by a bridge to the final assembly building.

As these various sub-assemblies are completed, they are placed upon specially constructed trucks. The Mercury on Run Number 3 then comes along and carries those truck loads to the final assembly stock room on the second floor of the final assembly building.

While the actual ground covered by this driver is not so great, his speed is diminished by the necessity for going up and down on the elevator. Upon him depends the supply of finished parts for the final assembly line, and he is kept continually making his regular round.

Run Number 4 covers the stamping building. The man on this route takes the finished stampings to the stamping inspection department, located in the same building, and plies between the stamping building and the final assembly building. His route consists of a large number of very short runs, so that a time schedule again is not feasible. It should be noted, however, that in this, as in every other case, the driver has a definite restricted territory and specific duties to be performed.

Even in the "best regulated families" every action or operation cannot always be fitted into a groove. So with this efficient trucking system. To care for the different trucking needs not covered by the specific routes, the Mercury on Run Number 4 performs miscellaneous service. This does not mean, however, that it runs aimlessly about the plant at the beck and call of everyone. It works only on written orders from the trucking foreman.

The Run Number 4 driver gives two hours each day to the oil stores department, two hours to the receiving dock, and about five hours to miscellaneous dies and haul needs.

The other regular run consists of carrying scrap to the salvage department from the various departments of the plant. One extra Mercury is held in reserve, to take the place of any other Mercury which may have to be laid up temporarily for repairs.

On Run Number 1 and Run Number 2 very long trains are usually carried, averaging between 20 to 35 trucks. The length of the trains is limited rather by the possibilities of speed, and safe and efficient handling than by the ability of the Mercurys to pull the loads. On Run Number 3, for instance, long trains of this kind cannot be pulled because of the necessity of using the elevators.

By these systematic methods of truck operation the material is handled almost twice as rapidly and efficiently as before the methods were installed. The transportation foreman has a definite check on every train, knows approximately where it should be at any given time, and is able to check up very closely on any loitering or inefficiency on the part of the drivers.

At one time helpers were sent along with the driver of each Mercury, but experience has shown that far better results are obtained through the present method. The truck trains are made ready for the Mercurys, so that the driver does not need a helper. It is found that there is less loitering, horse-play, etc., under this system, while less time is actually spent in preparing the trains and getting them under way.

Before the present system was installed, there was considerable delay in the distribution of material, although three more men were engaged in the work of taking it about. Material is reaching its destination on time, and the flow of work through the plant is thereby accelerated materially.

Even under a system of close supervision, however, a good deal depends upon the men who are actually driving the Mercurys, according to the transportation foreman. Where the driver is intelligent as well as interested in his job, he can facilitate the movement of material to a great extent; he can readily meet the small difficulties which must constantly arise in any such job; and he can act effectively without having to delay proceedings for minor instructions. Although the pay for the Mercury drivers is not high, the job offers certain opportunities which appeal to some wide-awake young fellows. It takes them around to the different departments of the plant and allows them

to learn a great deal about the general manufacturing processes, if they have a desire to learn. It enables them to see and understand a large number of jobs, and perhaps to choose some better job or trade into which they would like to go at a later time.

The results achieved by a close analysis of the intraplant trucking problem at Studebaker indicates that money can be saved and production speeded up at the same time through a careful study and operation of this phase of material distribution. It is a factor of the production problem that has not been studied as closely as some others and in many plants offers opportunities for improvement.

Economical Forming of Storage Batteries

Installation of boosters at the Prest-O-Lite plant permits batteries which are undergoing forming operations to be discharged back into the line thus saving much energy and reducing cost of manufacture.

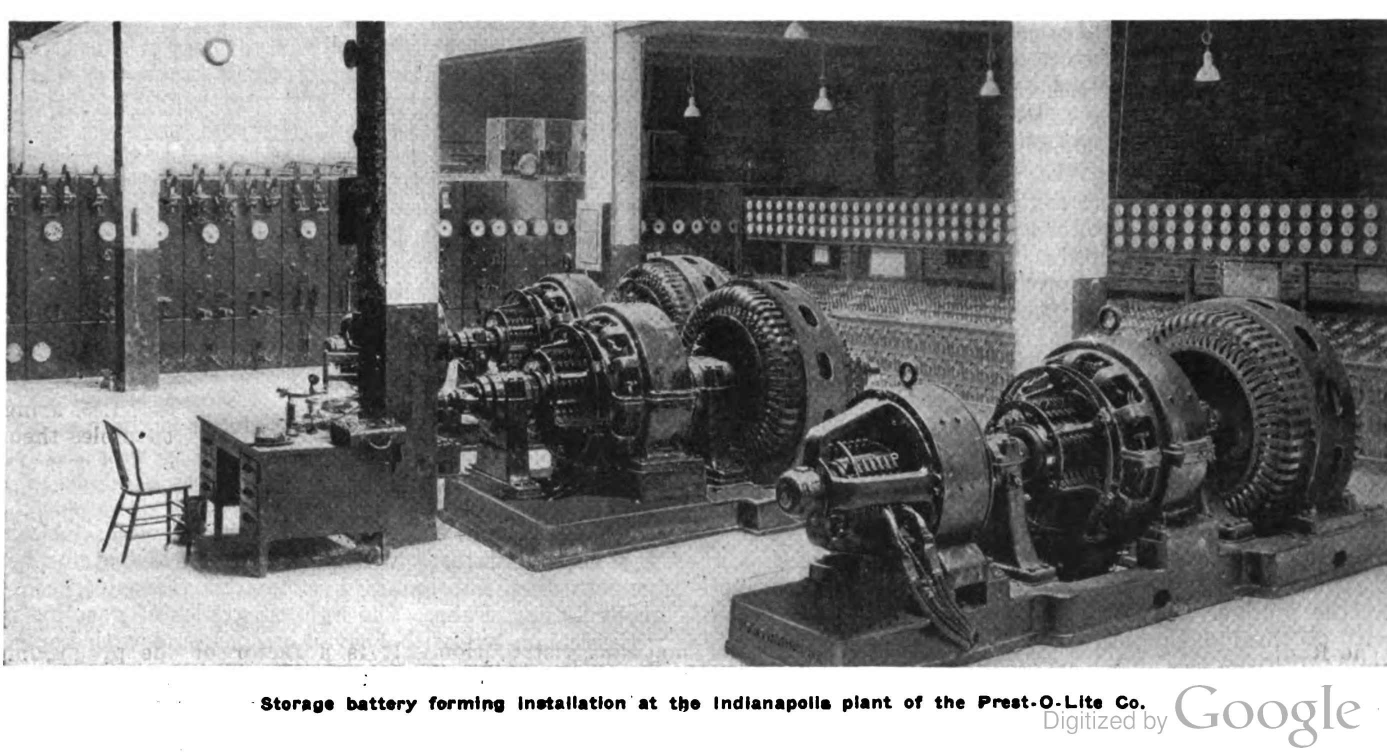
STORAGE batteries, before they are ready to leave the factory, are subjected to a number of long charges and discharges in order to properly form the plates, after which they are given a final charge. This requires a considerable amount of energy and usually forms an important item in the cost of manufacture of the batteries.

At the Indianapolis plant of the Prest-O-Lite Co. this energy is furnished through synchronous motor generator sets converting the energy from 4100-volt 3-phase alternating current to 250-volt direct current. In the photograph are shown two 625-hp. and 450-hp. machines. An 875-hp. machine will be installed shortly. The feature of this equipment is the use of three units for each machine, the third unit being used as a booster to allow the storage batteries to be discharged directly back into line.

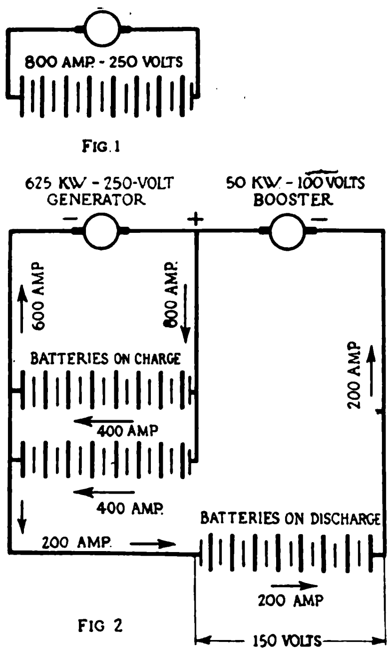
The method of accomplishing this is shown in the accompanying diagram of connections, and can be understood by an explanation of operating conditions. For charging, batteries are connected across the 250-volt generator in the regular manner, the generator (Fig. 1) delivering 800 amp. for charging various batteries, each having a suitable charging rheostat connected in series therewith. If several other batteries are connected to the discharge circuit, the conditions shown in Fig. 2 exist. These batteries are connected in series with a booster which composes the third unit of the converting apparatus, it being a 100-volt direct-current machine. Assuming that the batteries on discharge deliver 200 ampères through rheostat to the negative terminal of the booster and the voltage is thereby raised 100 volts, the batteries on discharge will develop approximately 150 volts, which with the 100 volts developed by the booster, causes the discharge circuit to pump 200 amp. into the 250-volt bus. Therefore, with a current of 800 amp. flowing through the batteries on charge, only 600 amp. is delivered by the main generator because the discharge current is delivering 200 amp. to the charging circuit.

The main object of this booster is to increase the capacity of the charging equipment. That is—with a standard motor-generator set, the number of batteries which could be charged at one time would be limited to the capacity of the motor-generator set. With the addition of the boosting generator on the same shaft the effect is obtained of increased generator capacity. For instance, in Fig. 1 the 250-volt generator is delivering 800 amp. for charging or is producing 200 kw. Now, if a 200-amp. 150-volt battery is placed on discharge, 30 kw. are available. In this case, the generator will be required to deliver only 600 amp. or 150 kw. However, to raise the voltage of the discharging circuit to 250, 200 amp. at 100 volts must be produced at the booster machine. This amounts to 20 kw. Therefore the same number of batteries are charged with only 170 kw. being taken from the main source of supply neglecting the losses in the machines.

In this plant, the facilities for charging the batteries are comprehensive in principle but simple in operation. Each battery circuit is controlled through bench board panels equipped with knife switches, rheostat handles



Storage battery forming installation at the Indianapolis plant of the Prest-O-Lite Co.



Figs. 1 and 2—Diagram of connections of battery forming plant

and ammeters. On one side of the room there are 288 of these circuits and on the other side there are 180 circuits. Two operators can easily handle all of these circuits and thereby charge and discharge a great number of batteries at the same time. One of the interesting features of this charging equipment is the method of mounting the grid rheostats. On the side shown in the photographs, these rheostats are mounted nine in a row directly behind and on a level with the board. On the other side, however, there was not enough space for this kind of mounting so that some of the resistance had to be mounted above the top panel. This type of mounting precludes accessibility but as in two years of operation there has been no need of repairs on the 288 circuits, such facilities are thought unnecessary.

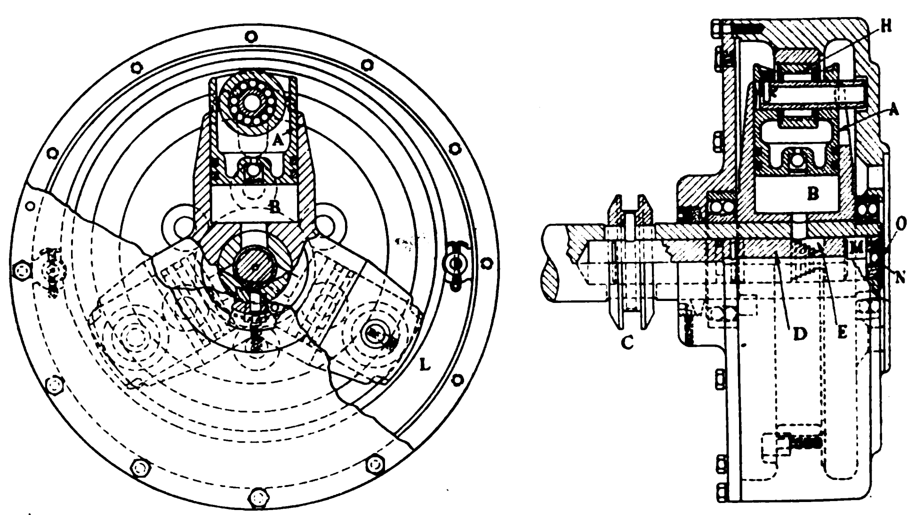
At the end of the room is the switchboard controlling the motor-generator sets. The 4100-volt energy enters through an oil switch and then goes to the main bus. The motors of the machines are connected directly to this bus through separate oil switches. No starting apparatus is necessary because the motors are designed to start as induction machines.

On this switchboard are also contained the panels controlling the power circuits for the rest of the plant.

A Hydraulic Type of Clutch

A CLUTCH which is claimed to afford the desirable feature of easy engagement and positive driving lock has been developed. The feature of this clutch is that it can be engaged with any degree of slippage so that the power of the engine can be developed as desired and yet smoothly and evenly transmitted to the rear wheels at extremely low vehicle speeds. When disengaged the clutch functions in reality as hydraulic transmission.

The clutch is built inside the flywheel in the usual way and is inclosed. It runs in a bath of oil. In the sectional illustration the pistons are shown at A. Oil is imprisoned above these pistons in the cylinders B and can be by-passed from one chamber to another above the pistons by moving plunger D to open the by-pass shown at E. The three pistons A ride on roller bearings H against the eccentric ring L, which is ½ in. off center, thus allowing the pistons to make a 1-in. stroke. When the clutch is released the continuous by-passing of oil from the three chambers B through E maintains a constant equalization of pressure above these pistons so that the roller bearings are in idling action against eccentric ring L, and the pistons are in constant pumping action.



The Hubbard Oil Clutch.

When the clutch is engaged plunger D moves forward to close by-pass E, thus locking the pistons A against the eccentric ring L. This locking action results from closing the by-pass from oil-filled chamber B, the oil remaining under each piston. It is impossible to drop the clutch into sudden engagement, for at the end of the plunger D is a space M which acts as a dash-pot. As the plunger D is pulled back, this space M is filled with oil through the ball valve N. If the foot is released suddenly from the clutch pedal the oil within this dash-pot M flows out gradually through the by-pass O, this causing smooth gradual engagement of the clutch.

It is evident with the hardened steel roller bearings which are rotating about the contact ring during slippage of the clutch that there are no parts in the clutch which can be worn by slippage and consequently the driver is free to slip the clutch as much and as often as he pleases, thereby giving him additional traffic control without in any way damaging the clutch.

The pressure required to release the clutch is equal to the tension of a spring only strong enough to hold the weight of the clutch pedal. The clutch is the product of the Hubbard Clutch Co.

BENZOL and alcohol are readily miscible. Alcohol-benzol mixtures will not freeze at low atmospheric temperatures, but unmixed commercial benzol freezes at about 23 deg. Fahr. The lightest grades of gasoline mix with alcohol, but with heavier grades, and with kerosene separation occurs. Separation is prevented by addition of a mutually miscible solvent such as benzol.

Human Study a Necessary Factor in Automotive Sales

Now that it is necessary to discover merchandising in the automotive field, the question is uppermost as to the proper place to look. Most searchers have turned to statistical tables. Here is a suggestion for another field.

By Harry Tipper*

I WAS in Detroit last week visiting with some of the people who are at the center of the automotive manufacturing, attempting to discover what the conditions were from the production standpoint. They are better than we could expect in view of conditions.

The manufacturers are moving forward in production further than we had any idea of at the beginning of the year, and those manufacturers who have maintained their product on a basis of stability and their organizations on a basis of fair efficiency are moving ahead a little faster than the average. The orders up to June show a very surprising volume. In the replacement business the cars and trucks that are in use are apparently beginning to absorb their usual quantity of replacement materials. Stocks in the case of jobbers are beginning to move once more and they expect to keep them to a normal basis during the rest of the season. So the outlook is better. We had a rather severe shock but the possibilities are that we shall have sufficient business to take care of on the basis of present industrial conditions.

We have to discover merchandising in the automotive field now. We have not had to do it heretofore. The entry of a new convenience of that kind into the world's possibilities required no particular merchandising. It required only more or less effective production in order to bring it into use. At no time have conveniences of communication or transportation required very much merchandising to sell them; they have been seized upon, always, with avidity by the world's population because progress depends entirely on communication and the ease of transportation itself. The automobile offered a flexible unit of transportation, under the control of the individual, and this opened up an entirely new field of social and industrial possibilities to the individual and the community. It was seized upon just as fast as we could turn it out—people desired to have it and we have not yet fulfilled the desires.

The future of the business depends on our intelligence in knowing the conditions and not on any supposed saturation point or limiting point in the possibilities of use. As a matter of fact, we are entirely too prone to view industry from a static standpoint, as though we could take a stationary and fixed view of it. We talk about economic conditions of the country as being against the possibility of consuming more or less of this or that material, but we forget that the economic conditions of the country depend upon our productivity, on the increase of our population, the growth of our wealth and a number of factors that are not stationary in themselves but are constantly moving. Any view we take of industry must agree with the dynamic character of the industry itself. It is always moving and the automobile business has not moved in the volume that it must approach.

It might be worth while to spend just a minute on that point because the thing has grown so fast that we are a little doubtful if there is not some magician's trick in it that will leave us in the lurch later on.

In the passenger car business, we have established so far that a car on the present basis of production and efficiency will last a little more than five years and on that basis we shall have replacement requirements, at the end of five years, of about 1,700,000 automobiles merely to keep the present number going. We have exported a few cars in a single year abroad, but we have a market there that we have not yet touched. We must supply cars to the great foreign countries of the world, because there is no competing country manufacturing on a mass production basis in automobiles. For medium low-priced cars and even high-priced cars there is no corresponding value in the largely hand-work or individual production of the other manufacturing countries. There is no possibility of getting the volume out of those countries.

We talk as though mass production could be gained in a few months by putting a little machinery in the plant, but it has taken the automobile business ten or fifteen years to standardize for mass production. They have not begun to standardize the work in European countries. They have ten or fifteen years of standardization work before them. Organization cannot be planned in a few months unless the elements have been established and these other countries have not established organization for mass production. The call came to us all last year in our office from people all over the world, importers, distributors, dealers in cars and trucks and tractors wanting to know about the American product, claiming it the only thing they could get in a reasonable time and in reasonable quantity. This offers a foreign market two or three times as large as at present and in itself is enough to make the outlook somewhat inspiring. The matter of the possibilities is not a discouraging one and the only discouragement we can get is from our lack of analysis of the situation. The reason for our lack of analysis is the fact that we have not been obliged to analyze heretofore. We have not had to know why automobiles were bought. We are ignorant of many of the merchandising necessities. We must now discover what these necessities are and I wanted to suggest a few things that enter into this.

First of all merchandising is a human matter. Our

*An address by the Business Manager of AUTOMOTIVE INDUSTRIES before the Advertising Club of the Brooklyn Chamber of Commerce.

market statistics are of no value unless they tell us a human story. After all, buying is done by human beings and because of human reactions. It is affected by tradition and association just as much as it is by economics. The desire to buy a single product may rest in the mind for years before the possibility of buying comes along, but when the money is there the spending of that money is influenced by the long controlled desire. We must understand the human reaction if we are to understand the market conditions.

What we are trying to do in merchandising is to produce a favorable reaction toward us on the part of every individual and have that result in agreement for the exchange of a product. We have been too much inclined to consider markets as based upon statistics and economics. As a matter of fact, the statistics and economics are the outcome of the previous condition of the market and all they can do is to give us a general idea of the flow and ebb of human actions in connection with industry and merchandising.

We have not studied human reaction very far in the automotive business. Along in last August when the drop began to come, I was asked by some of the manufacturers what would be the probable return and I made the statement then **that the social buying of passenger cars would begin before the industrial buying of trucks —long before any business buying—and I based it upon the fact that the social buying would come first from those people who had had a long desire to own a car and found it impossible for one reason or another to do so.** Among the individuals in the population there is always money to be spent, even when money is scarce in the general sense.

I know in my own travels of certain general classes who had been out of the buying of cars all through the war but who had never lost the desire for a car, who were beginning to get in shape for the buying of cars. That is what happened. The volume of production in passenger cars to-day is much larger than the production of the truck, simply because the human reaction is different and the desire to buy on the part of the individual is more insistent than the necessity for buying on the part of business.

That is something we have not paid much attention to in the marketing of automobiles. Similarly we have not paid much attention to why the thing is bought. The sales reasons which you give for a car or any other product are frequently not the reasons why people buy at all. You have insisted on the technique as well as the details of the car to a degree which might have been all right in the beginning but is no longer necessary. You have neglected the insistence upon a lot of other details which are absolutely necessary for a favorable reaction on the part of many buyers.

I watched in the shows last year and this year and heard the conversation between the people who wanted to buy and the people who were selling. A lot of information was displayed on the part of customers about the technical details, but the reaction after they left the booth, the conversation among themselves, did not go much on the technical details. It went upon the conveniences of the car, of the shift lever, on the room in the front seats and the character of the upholstery, upon the feel of the tonneau seats and of the probability of its riding easily and matters of that kind connected with the immediate comfort of the passengers, but I did not notice the insistence on those points in the booths.

We do not study quite sufficiently people who buy. It is a curious thing. I was talking to Mr. Clark at lunch and he found it rather extraordinary, that in an investigation made not long ago not one of the owners approached knew what tires he had on the car previous to the last two that he bought, and a great many of them did not know what tires they had on the car at all. That seemed extraordinary and he felt there must be some mistake, but it was a very careful investigation. There are many reasons for that, but one of the important reasons is that the buyer does not buy tires for the reason that the manufacturer thinks he does. Many tires are bought because they are recommended by a neighbor or the dealer and many tires are bought because they justify themselves among the neighbors or to the dealers. Many buyers refuse to purchase tires because they think a great deal of luck enters into them. They find that they vary considerably in mileage and they think it is more luck than the manufacture when they get a good set.

I might run down a number of products and show you that the buyer of products reacts toward the product in an entirely different way from what we suppose.

We are too much engrossed by the technique of our business to know what the other fellow thinks about it and our sales approach and how merchandising arguments are affected by that fact.

Then we have been merchandising cars and trucks without having divided the buyers up into their ordinary groupings and know how they are affected in their purchasing by those groupings. It is interesting to me to know how many trucks are used in the different lines of industry, but I am sorry to say that I am unable to find from the truck manufacturers themselves any who knew which was the biggest market and the next, and the next, and the number of trucks that entered into each market. They are unable to divide their market up and consequently they do not know how to approach that market.

Then we have not determined how the division of the market affects the product itself; how much people are willing to spend and what they demand in the way of individual differences for the expenditure. There are a large number of small concerns building a few trucks a year. They are doing a successful business because they are building the bodies of the trucks to suit the individual requirements of the individual customer and building the service to suit the requirements of its customers. We have not measured how much the divisional groupings of the market require a change in the product to meet those conditions, because we have not studied the probable reactions of the buyer sufficiently.

Similarly, we have not measured the channels of distribution. I was mentioning again at luncheon to Mr. Clark the subject of branch houses for the tire people and I mentioned the fact that very few of the tire manufacturers know that the branch house came into the rubber business long before the tire was a real factor, it being the mechanical goods that they originally carried. Tires were simply added later on to those other lines.

We have not understood what are the normal channels and what are the abnormal channels of distribution. We think we can talk about eliminating the jobber and going to the dealer, eliminating the distributor and going to the jobber and going to the consumer as if it were a matter of decision. These lines of distribution have been worn deep by custom and tradition and habit of buying. We cannot simply break down those banks and put the stream in any other channel by a mere decision. We have not learned why certain lines of goods were

distributed in one way and why some others had found another channel.

Furthermore, in the automotive buying or merchandising we have not yet determined the relative importance of standardizing lines or of individualizing them. Every merchandising effort is an attempt to take your product out of competition and give it an individual character. You wish to take it out of the general acquaintance and put it into a personal friendship; that is, take it out of the competition or comparison and put it into an individual place for itself. So that every merchandising effort is to individualize the product. Time after time when the problem comes up to us in the shop, a manufacturer wants to duplicate what the other man is doing, he wants to make a package of about the same character, he wants to make a product of about the same character, and wants to go through the same methods of sale organization without determining the fact that he must attempt to individualize his work. That individualizing will rest upon certain points of difference.

Instead of attempting to differentiate himself from the others he attempts to classify himself with the others and makes it more difficult to overcome the sales resistance. We have not measured the value of standardized practice and the value of individual methods in merchandising. We have been largely impressed by the value of standardized practice in production and suppose that the same thing operated in sales.

Finally, we have had no basis for measuring the value of merchandising operations outside of the personal salesman. We know how to measure the personal salesman because we look at his order book and the credits at the end of the year. We know what he has done—what we have delivered—and we can measure his value upon that basis. In advertising—that is the mass salesman—sales promotion of various kinds, we have no means of measuring their value. We do not know how much our advertising has contributed to the sales; we do not know how much our sales promotion work has actually increased value, and we are frequently without any information which would indicate the extent of service we can allow and the character of that service. We have no basis of measurement of these points and, consequently, we are always experimenting, hoping to arrive at some groundwork, without any analysis being made and always arrive with no basis of measurement in the end.

So long as times are good we will accept the expense for advertising and the requirements of the service and O.K. them, without any understanding as to why they are in that shape, but when times are bad we ruthlessly cut them in two and cut off one-third without any understanding of the reasons. Why? There is value in all these methods, but most of the value lies in the human reaction and not in the statistical information. Out of a thousand things that pass your vision to-day, you record one on your consciousness. Out of a thousand things that are put before your eyes, pass your eyes, in advertising, out of a thousand sounds that hit your ears you select one or two to be remembered or recorded. It is automatic. How do we know that the advertisement we are putting out to-day will be one of the thousands that will be rejected or one of the few that is remembered? On what basis do we measure that?

We simply go blindly into the market and throw out our advertising matter just as if I threw it out of the window here, in the hope that people would pick it up as they go along the street. For this reason we waste a tremendous amount of effort in our sales promotion and sales work. We do not know why people act and, therefore, we cannot arrange our methods to agree with their reactions.

As a matter of observation and effect in advertising, in the mass sales work, people react to very few things. If you will think back and analyze yourself from day to day you know that there are very few things that interest you, very few; your business, certain portions of your business, not all of it in detail, your surroundings at home, certain things about it, certain things about your social life; there are very few that you examine in detail or are interested in. You probably look at half a dozen things and you are through. That is the extent of your examination and interest.

Now those interests govern your reactions very closely and if I wanted to have you react pleasantly and favorably to me I must know your interests and apply my own interests to those interests, and not only that, but also at the time you are interested in them.

There is no use for me to get you interested in the details of your business when you are wondering if you will make the put on the ninth green.

There is no use of me trying to get you interested in reference to details about church work when you are just stretching for the seventh inning.

The associations that you have are separated very carefully into compartments. The interests that you have are differentiated so that you will take up one interest where it belongs at the time that you are working on that.

If I want to advertise to you, impress you and get the recording of my impression on your consciousness, I must suit my interest to yours.

We do not do that very often. We have so large an amount of technique, without fundamentals, in our work that most of our work is scattered all along the surface, whether it touches our customers or not.

We presuppose that other people are interested in the things we are interested in. I am presupposing you are interested in this address—the chances are you are interested in a small part of it and probably will not remember more than one thing. You will forget all but a sentence or two. But personally I am apt to presuppose you are interested, because I am interested. All through life we are conducting our business on the presupposition that other people are interested in the things we are doing. We go ahead blithely telling about our production without knowing the other man's interest. Frankly, before we get very far in merchandising, we must be able to step outside our own interest and watch the people objectively so that we will not be submerged in our own technique when we approach the other fellow. Merchandising in the automotive field is no different from any other.

The merchandising outlook is good provided we have the intelligence to tell the people that we will meet their problem and can give them what they desire. They desire automobiles—they desire automobiles to run. They expect to have them continue to run and if we intelligently work out our problem I do not think we shall have any fear of the business.

A NEW rust-proofing process, which has been successfully used for bicycle parts, has been evolved in the research laboratory of Rudge-Whitworth, Ltd. This consists in boiling the articles to be treated in a solution of hydric-phosphate of iron which produces a dark gray finish practically immune from the attack of rust. It is said to be very much more rapid than Coslettizing and has no effect upon either the strength or temper.

What You May Expect From Foreign Advertising

Again it is said here that foreign advertising, and we might add merchandising, is not distinctly a different problem. Advertising and selling, like the people, are not vastly different because of the lines on maps.

By A. B. Cole*

FOREIGN advertising is an investment to insure sales, and when it ceases to be an asset it is time for the liability to be wiped out. Many concerns have treated their foreign advertising as a side issue, and carry it as a heavy liability, owing to the lack of proper co-ordinated sales and advertising effort behind a set campaign or advertising program. It is natural to expect just as much from your advertising appropriation as from any plant investment. A certain investment in advertising can be made to produce returns that will parallel, if not exceed, any other investment of equal amount.

It can be made to—

Add to sales directly,
Add to sales indirectly,
Create good will for manufacturer and commodity,
Change living conditions,
Analyze markets,
Discover demands for products when none appears to exist,
Open channels of distribution,
Successfully counteract resistances both active and passive.

It is gratifying to observe that there are many large organizations using foreign advertising to search out the markets of the world. However, we need a more universal revision of our sales organizations on the part of the medium sized and small manufacturers in this country. Many of these companies are doing 25-, 50-, 100-, and in some instances a few hundred thousand dollars' worth of business a year, and were the executives of many of these companies to take a greater interest in their foreign trade and rightly use the experience in what has made them what they are to-day, co-operate with their sales and advertising departments, their foreign trade would increase rapidly. This rightly applied will place their export trade on a permanent basis. Some small manufacturers are doing a large foreign business, and in every instance it will be found that they are conducting their foreign trade along fairly practical lines—in other words they are thinking internationally.

Then, again, there are larger interests that should be selling their products in every country on the earth, who are practically doing nothing. Their foreign sales promotion and advertising methods are haphazard, they are not concentrating on this commerce of the highest order. On account of the wonderful experience some companies have passed through during the last few years, they have overlooked the greater factor that makes any industry worth while—that of business building for the future—that great insurance which not only sells service, but causes one to point to a particular concern as a great international institution.

A plan is essential; know first what is desired to be accomplished; then as a general would deploy his armies, divine available forces to overcome obstacles. These forces must be used in their proper relation to each other, and, speaking of forces, international salesmanship in its broadest sense is meant.

Generally speaking, there are two kinds of selling: making use of existing markets, or being an opportunist; and making markets and using creative salesmanship.

ADVERTISING is nothing more than creative selling; and sales promotion in its final analysis consists of the use of three mediums:

Space—this includes from newspapers to motion pictures,
Direct-by-mail merchandising,
Salesman.

The foregoing media must be used; some or all, according to the necessity of the products or scope of the company.

After all, building up a foreign trade is nothing more than creative selling.

The foreign field is looked upon by many as a mystery. Certain localisms influence the judgment out of all proportion, owing to the lack of an international mind. Because toast has never been used as a food in Japan is no proof that a market cannot be built up for electric toaster stoves—educational work may be necessary first.

Advertising in its true sense can be used, and will produce a pre-determined result, provided proper analysis has been made of fields to be covered.

Like investing in anything, consideration must be given to the question, "Will the returns warrant the expense?" It is surprising what can be done with a limited appropriation—if care is taken to be sure every part is co-ordinated.

Human nature is very much the same the world over. Under the skin we are similar. There are certain appeals which apply to all of us and if these appeals ring with sincerity they are just as effective in Brazil as they are in China or the United States. Speaking of appeals, we mean those which affect the emotions—fear—comfort—gain—fight or pride.

Granted, the general physical conditions of a race must be considered. The so-called Latin does not like to be hurried, consequently "pep" copy lacking dignity would not pull as well as good descriptive sincerely logical copy with, perhaps, the pride appeal. Of course, the "copy" would depend upon the commodity and the locality.

*Director of Publicity, Westinghouse Electric International Co. Paper read at the Eighth National Foreign Trade Convention.

If we consider the underlying emotions common to all, the problem of foreign trade is not nearly so complicated in its fundamentals. True there is naturally, due to the wide field, a mass of detail, but this after all can be classified until it becomes mere routine.

If you have a product of merit, the thing to do is go out and sell it. First, find out how great a resistance you have, perhaps using advertising to determine this; marshaling the means available so that each and every one does its full complement of work, eliminating everything that does not help in the plan. If it does not help, it is a hindrance.

Creative salesmanship, energized by the master force visualization, sells the goods. This is true, but visions and products of the imagination, while wonderful are merely idle dreams until will power and hard work put foundations under them, after which they become realities. And the tool with which to build the foundation of any business, whether it be a corner grocery or international company, in "character" is advertising. However, it must be employed with as much care and common sense as in the buying and selling of any commodity. Return on investment in advertising should be in proportion.

Customs change overnight; they are after all only the surface. Some ten years ago all the Chinese wore queues. They were gone almost overnight. The advisability of catering to customs should not be discounted; they are an entering wedge.

We think of the customs of a country. We hear much of it these days, but in the essence what is selling anyway, but the changing of customs, the changing of another mind to conform with your ideas? It matters not whether the idea is good or bad.

Being specific, as to what may be expected from a foreign advertising appropriation, one of the primal results should be a world-wide or a country-wide acquaintance with the manufacturer, large or small, wherever advertised, namely, institutional advertising. Although many do not agree as to the value of institutional advertising, in many instances remarkable results will be obtained from a well planned campaign of this nature. Particularly gratifying results are obtainable from native mediums and with such a campaign, followed by a definite consumer campaign of commodities, a good foundation is laid.

It is highly essential that all advertising activities be properly supported by appropriate window trimmings where possible, and by well planned, and executed, dealer and consumer literature.

In export merchandising, the returns from this angle of advertising are in proportion to the aggressiveness with which the field organization as well as the home organization works. You can lead a horse to water, but you can't make him drink. So it is with the heavy machinery salesman. While he may occupy a prominent position in his own little sphere, his gross sales could be increased many times were he to analyze and dig deep into the desires and requirements of the merchants around him. Proper merchandising should always be sold with a resale feature in view. Thus, many times the aggregate of a salesman's efforts in selling merchandising lines is often greater than heavy machinery sales, on account of the duplicate mail or repeat order.

There is one advantage that we must remember in relation to our foreign competitor, and that is, the foreign house does not help his dealer move the goods off his shelves as we do. He does not feel obligated to furnish all the dealer helps that are prevalent among our up-to-the-minute advertising and sales organizations.

The Latin-American, particularly, is fast becoming cognizant of our business methods, and it is gratifying to say these methods are being favorably received. If you can show a merchant how by better merchandising he can turn over his investment several times per year instead of once, he is not going to forget the favor; and your advertising backed by such sales promotion efforts will more than pay out handsomely.

Above all, the foreign advertising appropriation should produce confidence in customers, stimulate consumer demand and keep goods sold.

As a facility for handling foreign advertising, the great importance of using a first class foreign advertising agency must not be overlooked. In this connection these points must be duly considered:

1. A foreign advertising agency is a prime essential for any extensive export operation. However, this agency must have had world-wide merchandising experience.

2. The advertising manager of a manufacturing company can obtain the best results if he does not overlook the fact that it is highly essential that the agency have his utmost co-operation in order that it may become conversant with the technicalities of his marketing problems. It stands to reason that an outside organization, being retained to assist any manufacturer, should not be expected to be any more than space brokers if the advertising manager does not assist the agency from all standpoints. If co-operation for the ultimate success of an undertaking is required, it is certainly the case in this particular relation.

3. In many instances, foreign advertising of a manufacturer depends on what the manufacturer is to-day. Too many manufacturers treat this subject as one totally foreign to their business, while in reality it is the domestic business told in another way.

4. Practical experience must be injected into foreign advertising.

The foreign agency should be treated in the same way as the domestic agency—such procedure is imperative.

The success of an advertising appropriation does not depend wholly upon media and copy, but the whole plan affects the net result.

American manufacturers must extend this world-wide facility—trade, and this can be obtained only through the co-operation of all the departments from the president to the various committees, down to the shipping clerk.

Who of you have considered these factors in order that proper analysis of your foreign advertising might be assured?

Here we have some of the factors that insure success in foreign advertising campaigns.

All efforts must be closely allied with the local advertising and trade paper compaigns in the particular countries through the assistance of the field organization.

The field organization must be completely sold as you proceed to unfold this profit-sharing method of advertising. Bear in mind that you must make advertising profit-sharing if you would succeed. It is hardly necessary to elaborate on the different forms of advertising, so similar in many cases as that adhered to in this country, such as local advertising in newspapers, trade papers, and bill posters, all of which you are familiar with; and then there is general advertising literature, specially printed matter designed for dealers' use; circular letter campaigns, and all these that I have enumerated, you realize the value of these campaigns. Why we do not adopt these methods more nearly universally in foreign trade is a great conundrum. The common procedure, if put into effect, should place us in a position that we are bound to succeed beyond all expectations.

Recording results from advertising is a real asset—

is a key to the future progress in the development of foreign trade. The most efficient way is the card system, with a practical follow-up plan. The inquiry that you received six months ago may have cost you 35 cents or $35. Perhaps it can be turned into a substantial order if you will review the hidden information within your business. I believe that the loss from neglect, improperly following up of prospects and proper handling of correspondence, has cost our country millions of dollars and much prestige in foreign trade. You may have had a remarkable sales organization; the new era of things will demand that you become as familiar with the facilities of your agents and branches in Hongkong, Buenos Aires, and Melbourne, as in the instance of your Chicago, Cleveland and New York organizations. An agent or a branch of a manufacturer abroad is an integral part of the successful advertising campaign.

The expression "foreign trade" covers a vast amount of territory and one is prone not to analyze intensively the changing conditions of the factors that make up the whole undertaking.

"What I May Expect from My Foreign Advertising Appropriation," gentlemen, is exactly the mission set forth by my company for establishing its policy.

1. We expect that the Westinghouse Electric International Company shall be known favorably throughout the world.
2. We expect that the foreign buyers of the commodities which we make shall know us to be a fair and honest house.
3. We expect that the salesmen representing us in foreign countries shall be proud of the fact that they are working for such a company as ours that is backing them up in every way possible in giving them the entrée, and in assisting them in sales, that the business in their territory be increased and that the great godsend to humanity, the uses of electricity, shall be known all over the world.
4. We expect the dealers and distributors who are handling Westinghouse products to be as proud, as the agency for our goods, as we are proud to have them for our agents.
5. We expect that every dollar that we are expending for foreign advertising to-day will be planting seed of such productivity that it will come back to us in manifold increased sales.
6. We expect that the good word which we are spreading of our company and products shall last for all time to come, so that the name of the Westinghouse Electric International Company shall be the paragon for a good fair company which sells the best kind of goods it knows how to make.

Our foreign organization operates through the arteries of all civilized countries of the globe, covering a wide range of products, 300,000, touching over 500 industries, thus including anything electrical from a giant railroad locomotive to milady's curling iron and baby's milk-warmer.

We are offering engineering advice to many peoples on the earth. This is the world-wide vision that American manufacturers must inaugurate. It is this method of capitalizing the dollar that pays dividends. It is the contribution of this service that will give the world a more convenient "to-morrow."

It is this service that industry must render the world's commerce—one of the greatest missionaries for good, and, gentlemen, the effort that you put forth in behalf of foreign trade is going to make you and your industry bigger to-morrow. And remember that international trade affects every fireside in our great country. It is one of the serious problems with which we are confronted. The great manufacturing institutions of this land realize it. They propose to render this universal service to the world, and it is only through service that any institution has the right to exist.

The company with which I have the honor to be associated has always taken a broad viewpoint of the commerce of the world, like similar institutions unselfishly placing its huge organization at the command of the trade at great cost, along lines that are not prefixed with a dollar sign but basically having in mind the duty to help others, and thereby lessen the burdens of the peoples of the earth.

Automobiles in Japan

THE following extract from a recent issue of the London *Times* gives some interesting data on the status of the automobile and truck in Japan.

"The use of motor vehicles in Japan greatly increased during the war. In 1914 Japan possessed 353 motor cars and trucks for hire, while 713 were privately owned; in 1915 there were 419 of these vehicles for hire and 825 privately owned; in 1916 the numbers were 566 and 1082; in 1917, 1291 and 1381, and in 1918, 2473 and 2060.

"The registrations of motor cars, cycles and trucks show that these vehicles are chiefly used in the larger cities and towns. The country roads are not adapted for motor traffic, although this defect is in course of being remedied. In December, 1918, 1975 motor cars and cycles and 104 motor trucks were registered in Tokyo; 423 and 5 in Yokohama; 421 and 32 in Osaka; 263 in Hyogo (Kobe); 184 and 4 in Kyoto; 146 and 14 in Aichi (Nagoya), and 918 and 50 in other towns. On Sept. 8, 1919, 968 motor cars and cycles and 119 trucks were registered for hire and 1153 cars and cycles and 119 trucks for private use; in Tokyo an increase of 280 vehicles; while in Yokohama, 252 cars and cycles were registered for hire, and 286, with 8 trucks, for private purposes, showing an increase of 93.

Since March, 1918, the Japanese Government has attempted to stimulate Japanese manufacture of motor trucks by giving a bounty for each truck built in the Empire according to military specifications. These trucks may be used only in Japan, and must have a capacity of one ton or upward. The bounty paid does not exceed 400 yen (£40 at normal rate of exchange) per truck, but an additional sum of about 100 yen is granted for trucks used or hired out by a manufacturer. The owner of a truck receives a bounty of 200 yen, and is granted 60 yen per annum for five years toward its upkeep. Owners of imported trucks also receive some 200 yen per truck, and an annual grant of 60 yen for upkeep; these bounties are, however, paid only to Japanese subjects.

"The narrow crowd-thronged streets are prejudicial to the use of motor trucks, especially those required for speedy delivery of goods. Tokio, Yokohama and Osaka will probably be the chief market for motor vehicles until roads and bridges are improved in the smaller towns.

"More cars are required for purposes of hire than for private use, and the demand for taxicabs exceeds the available supply. There are motor omnibuses in Tokio which charge lower fares and render better service than the electric street cars. Small or medium types of passenger cars are generally preferred. There is a big demand for closed private cars on account of the dusty condition of the roads."

The FORUM

Hub and Wheel Standards

Editor, AUTOMOTIVE INDUSTRIES:

The articles by John Younger, published in AUTOMOTIVE INDUSTRIES of March 10, and W. J. P. Moore, published in the April 28 issue, have been read with considerable interest, and it is apparent that there are several other viewpoints on this subject of wheel and hub standards which have not been expressed in either of the above letters.

These articles would give the impression that the automotive industry exists primarily to furnish employment to certain classes of workers of which one is the automobile engineer. This is evidenced by the phrase, "there is a lurking suspicion in the back of my mind that such a standard may lead to loss of individuality." It is undoubtedly true that standardization may result in a certain loss of individuality to the engineer.

However, the industry must face this fact: The American public has let it be known in a most emphatic manner that less expensive automotive transportation is demanded. The problem of the engineer, therefore, resolves itself into the question of how best to discover the method whereby the decreased cost of automotive apparatus can be given to the public.

If this decreased cost can be obtained through the multiplicity of designs and through the free expression of the various idiosyncrasies of designers as exemplified in the 257 odd motor truck hubs and wheels which we now have, in place of the 10 or 15 necessary to fill the field—then no change need be made in our present practices.

If, on the other hand, we are to exhaust every avenue looking toward the production of more economical motor transportation, then serious consideration must be given to the reduction of the multiplicity of designs, and this invariably leads toward standardization.

This standardization is bound to come about whether under the auspices of automotive engineers or under the control of some one manufacturer or group of manufacturers. We already have one-half of the passenger automobiles made by one manufacturer. Certainly, this one-half is standardized. This brings up the question as to whether the cost of motor truck transportation will be reduced by standardization or by any other available means, or will some manufacturer develop who, through economical design and production, takes over one-half the motor truck industry as has already been done in the passenger car field.

Certainly, a standard that involves 10 hub castings, with the corresponding hub designs on complete wheel castings, and which does the work of 257 designs in the range from 1½ to 7-ton capacities, promises a maximum economy in front wheel production. Economies should certainly be expected from the steel wheel maker, the wood wheel maker and the bearing supplier and the axle maker.

The economy in direct cost of the motor truck need not stop as a result of this standardization but would extend also to the maintenance of motor trucks. One of the serious complaints of motor truck operators is the excessive cost of repairs and the loss of time represented by idle trucks while making repairs. The adoption of a standard front hub and spindle design will operate toward more economical truck maintenance for the reason that if the service department of the "A" truck does not have the requisite parts, the owner of the "A" truck can, in all probability, obtain service from the "B" truck agency.

In addition to the above economies, competition between the manufacturers and agencies should lead to reduced cost of service to owners which in the last analysis would be beneficial to the motor truck industry.

A word as to the economic side of motor truck development as affecting standardization should be of interest. The motor truck as it stands to-day is the development of many years' work—the almost life work of many engineers—in bringing the motor truck to its present stage of development. It therefore represents what the automotive engineering profession considers as essential in motor truck construction as evidenced by its approval of existing designs and on the basis of these designs, we have certain necessary selling prices, which prices are based on the most economical present day production costs.

This is the problem on the one hand. On the other hand we have the great American public which, within the past nine months has rendered its verdict to the effect that motor truck costs are too high and must be reduced. The new problems for the automotive engineer, therefore, is to comply with these insistent demands and develop motor truck apparatus that can be sold and operated at a considerable reduction in cost. If these premises be granted, it follows that the motor truck manufacturer in the immediate future is going to be successful in direct proportion to his success in meeting these new demands of the public for motor truck transportation.

The article of April 28 goes into detail as to the type of bearing that should be used on standardized wheel equipment for motor trucks and brings forward the statement that the ball bearing is the recognized world standard in every civilized country of the world outside of the United States. We do not know whether we are to infer from this that the good old United States is backward as regards its civilization, as evidenced by its quite general use of the tapered roller bearing in motor truck wheels. We do not believe the writer intended to convey that impression, but he evidently overlooks entirely the fact that the tapered roller bearing has now been adopted by some 66 European manufacturers of automobiles, and as regards world-wide distribution, it should be of further interest to note that it is available in the great distributing centers of the world, and that bearings of the one standard are manufactured in two plants in America and one plant each in England and France.

There should be no hesitancy, therefore, on the part of the American engineers in using the type of bearing that has made itself by service the recognized standard for motor truck front wheels, as this bearing is available for production and for service practically the world over.

The article of April 28 goes into much detail as to the standardization of other parts of automotive apparatus, much of which has not yet been brought before the

Standards Committee. It is our firm belief that as regards the type of axle for rear wheels, the best sections for tires, the method of attaching tires, it will be found when these matters are studied closely that many of these problems have already standardized themselves and the work of the Standards Committee will consist largely in discovering these "natural" standards and presenting them in a condition to be of greatest benefit to the automotive industry.

It is far from the writer's intention to go into detail on such matters as tire standards which have already received attention from, and is in the hands of, recognized specialists on this particular subject.

T. V. BUCKWALTER, Chief Engineer,
The Timken Roller Bearing Co.

Vital Importance of Mr. Tipper's Articles

Editor AUTOMOTIVE INDUSTRIES:

The articles in AUTOMOTIVE INDUSTRIES by Mr. Harry Tipper have been a source of great satisfaction to me, and I have been frequently tempted to write, congratulating you on the manner in which you are giving publicity in a proper place to facts which are of such vital importance and yet are so generally ignored by those who should give them greatest consideration.

As a member of the engineering organization in various corporations I have had ample opportunity to observe the losses both to corporation and factory workers from lack of sincere regard by the management for the workers. I have also had opportunities to try the opposite treatment on a moderate scale and have had the pleasure of seeing the men respond with far greater effectiveness than I had reason to expect.

Lacking the ability myself for such publicity work as Mr. Tipper is doing, I take great pleasure and satisfaction in reading his articles and in the knowledge that the work is being effectively and persistently carried on.

THOMAS S. KEMBLE.

Cleveland, Ohio.

Non-Corrosive Hard Metal Wanted

Editor, AUTOMOTIVE INDUSTRIES:

We are interested in securing information from concerns who can supply a non-corrosive metal as hard as steel and of 60 scleroscope test, to withstand the action of copper sulphate; probably a material that is high in nickel and copper. This material must be capable of being machined, hardened and of taking a high polish.

We wish to exclude stellite, monel, duriron and stainless, as for various reasons these materials do not satisfy the conditions as observed by tests.

DIAMANT TOOL & MFG. CO., INC.

Army's Interest in Highway Transport

HOW intensely the Army is interested in the work of the Highway and Highway Transport Education Committee was well stated recently by Col. Mason M. Patrick, in an address at one of the public meetings of this committee. After describing in some detail the army's transport problems in France, Col. Patrick said:

"Now, just a word concerning what the army itself is doing to further the highway and highway transportation movement. You have no doubt heard of the opportunities which are being given to men to learn while they are soldiers, to train themselves in order that they may be better citizens when they return to civil life after their brief service with the colors, and it is in just such schools that we are trying to fit them for real, useful work in connection with the enormous problem of road building, of traffic control, and of motor transportation.

"There are open to all these men numerous courses, for any of which they are encouraged to volunteer, and there have been engaged men as teachers who really know their jobs. It will be understood that we are taking a large number of young men who would never have any college or university training and many of whom lacked even the advantages of high school training. While we have no ambition, desire or intention of turning them out as college graduates, we do believe that in their three years' term of service we can make them better men, better able to earn their living, and with a sense of respect for law and order, which is a wondrous asset when possessed by the citizens of any country, and the lack of which may prove a country's undoing.

"In these army schools there are now enrolled 40,000 men, and they are taking courses according to their own likings, carefully guided, of course, but still leaving to them a large measure of choice in subjects as varied as music, stenography, dramatic art, blacksmithing, automotive trades, etc. Among these courses we hope to incorporate some which will fit many of these men to take minor positions with State, county or other organizations which are engaged in developing their highway systems. We hope to have given these men practical courses which will familiarize them with the materials employed, which will fit them to be foremen, or to operate any of the machines which are employed in highway building.

"Others will be given instruction in the management of motor transport, particularly with a view to fitting them to become what, for want of a better term, we may call fleet managers, men who will be capable of conducting numbers of motor trucks running between different points and transporting goods. To my mind this is one of the problems we now have to face and for which we must find a solution.

"Nearly two years ago, in writing to a young man asking advice as to the course of study he should follow to fit himself for his life work, I suggested this idea. It seemed to me then, and I think it is more apparent now, that in the future vast quantities of materials will be carried on our highways in these vehicles, and in order that this may be done most efficiently and most economically, it is essential not only that there should be men who know how to conduct them individually, but others who know how to combine them into large or small fleets and to manage such combinations in a way which will prevent delays, which will hasten the journey and which will do this without danger to other users of the road.

"The army's highway transport problem is to be assured that the roads over which it must operate are suitable, that they are sufficient in number, that they are properly located, and that the motor vehicles which we can procure will likewise be suited for army use. That this problem is solved aright is of importance not alone to the army but to the entire country, and we wish to assure all those who are as concerned as we with the prosperity and with the welfare of our country that the army will aid in this movement by giving all of the encouragement and help it can afford and by furnishing all of the information it has acquired concerning roads and motor transport."

Importance of Human Wastes in Industry

It is easy to recognize difference in economy between two machines. It is more difficult to determine causes of labor waste in producing these machines. Human waste can be determined only after the production effort. We have no method of measuring human capacity to produce.

By Harry Tipper

DR. GRIMSHAW, in an address upon economic matters, at a meeting of the faculty at the New York University some years ago, pointed out that labor was the only value. Nothing is of any value until labor has been put upon it, and its value is in proportion to the amount of labor required for its discovery and fabrication.

When industry is measured from the finding of the material to the use of the product, there is no value except the value of the time and effort which is required to bring it into usefulness. In the average individual establishment, the importance of the labor cost is understood but the elements of labor waste do not receive the same study. The direct labor used in fabricating the product is only a portion of the amount going to make the cost of doing business. Indirectly, of course, we are paying for labor when we pay for raw materials, buildings, machinery, printed matter and everything else that enters into the cost. Capital itself is only the product of previous labor stored in convenient form for use in providing future production.

When the matter is pursued logically to its final outcome, Dr. Grimshaw is right; there is no other measure of value except labor and all costs are outgrowths of labor costs. Without knowing the economics of it most of us are sufficiently aware of this to apply prices to labor cost automatically. The discussion of costs among individuals, in newspapers and in other public prints begins and ends with the labor question.. Whether we regard it as a problem or not, the question of labor is the paramount question at all times in industry, and the future of industry depends entirely upon progress in the direction of labor efficiency.

Labor cost must be measured in time. There are other factors entering into it, of course, but these also are questions of time. The rarity of the skill demands a greater payment because the time is limited and such skill can exercise itself only during that limited time.

A physician who is able to perform an unusual operation with success is paid an unusual amount because his individual skill is rare and he can only work the length of the day. He cannot duplicate his own skill. Similarly men who can organize their own work and organize the work for others receive more money, because that capacity is not usual and the exercise of it is worth a great deal of unorganized labor in the elimination of time and effort.

When all the modifications are considered, however, the problem of production is the problem of the amount of time required to do a piece of work at a given cost per unit of time. Even in the case of piece-work, it is the time which counts and payment by the number of pieces is an endeavor to secure a larger number of pieces for a given time.

The most important wastes in industry are the wastes of human endeavor. We have been very capable of measuring those wastes when they have been translated into materials, machinery, buildings and other tangible products. It is easy to recognize the differences in economy of two machines for a certain piece of work. It is much harder to determine the causes of the labor waste in producing these machines.

Limited as we are by mechanical measurements, we find it impossible to apply any measurements at all to the human being, and, therefore, our labor wastes are only determined after the production effort has been made and not before. When the man has produced his piece of work we can measure with fair accuracy the comparative value of the product. We have no means of measuring his capacity to produce nor the elements upon which that capacity depends in harnessing it to useful work.

While we recognize therefore the fundamental importance of labor, our discussions regarding it are arbitrary and without any sound basis of consideration. We cannot compare labor capacity and waste because we do not know either the possibility of practical improvement or the factors which will bring it into practical result.

In organizing the present work of industry, we have arrived at the point where the mechanical organization is sufficiently complete to be improved only with decreased speeds. So much past effort in the form of capital has gone toward the making of equipment which we use, so much ingenuity has been expressed in its improvement and it has become so large in its proportions that a measurable addition in the efficiency of any of its details can affect the total result but slightly.

This improvement may be lost through a slight decrease in the human efficiency or the mistakes of our organization from the human standpoint. Already in some instances, this difficulty is showing up so that within the next few years it will have a real influence upon the cost.

In the endeavor to secure accuracy from workers who do not understand the value of that accuracy, we have added to the supervision with systems of inspection handled by men who are themselves igno-

rant of the real importance of the work which they do. In some large industries, this centralization has gone so far that the improved machinery has not increased the accuracy materially in the last few years.

In some instances of effective organizations grown to an enormous size, the percentage of spoiled work has not decreased with the improvement of the equipment and the increase in the supervision.

The time of labor scarcity preceding the present depression showed the effect of decreased human efficiency upon costs and the great variation in human efficiency existing in plants of the same character drawing their labor from the same local market. This variation is the most important point of examination in considering organization changes calculated to increase the human efficiency.

As soon as the scarcity of the labor period was passed the human efficiency increased in many lines of industry within a few weeks, twenty or twenty-five per cent. Between plants in the same line of business and in the same locality, the difference in the human efficiency of labor ran as high as fifty per cent. Such variations in cost are too important to be neglected, they involve the whole economic position of the establishment. The reasons for the differences are worth examination and organization changes should not be frowned at where they offer a reasonable basis of increased efficiency, even though it may take some time to establish them.

One of the faults of the present mechanical system of organization has been the centralized control. It became easy to centralize all planning and all developments in the hands of a few executives as the systems of communication and transportation grew more rapid and more complete. These centralized systems reduced many of the supervisors to the position of the worker in their capacity to understand and their ability to conduct their operations in the business.

In many of these centralized systems we have endeavored to secure an understanding from the top over a large group of thousands of men, instead of securing it with the individual and in the small group. The responsibility has been limited to such a degree that few men have developed either an understanding or a capacity for decision in connection with their work.

These are elements which reduce the human efficiency or prevent it from developing. Inasmuch as labor cost is the important cost in industry, increased labor efficiency is the important problem of industry and future organization changes must be based very largely upon their ability to improve the human efficiency of the plant.

Health Service in Industry

A RESEARCH service financed and supported by employers is pretty certain to investigate and discuss questions of practical and immediate value to the production and organization problems of its subscribers. For this reason special interest attaches to the bulletin on "Health Service in Industry" recently issued by the National Industrial Conference Board. Aside from the carefully gathered and well-presented information which the pamphlet gives, the mere fact of its presentation indicates a growing realization of the importance of industrial medical work along with the other human factors related chiefly to a study of and attention to the individual.

The purpose of the bulletin is "to present a survey of what has been accomplished in the development of . . . the Medical Department, and to discuss methods of procedure which have been applied in individual establishments." It is based on material gathered by investigators and from questionnaires.

Much of the general material presented is worth the attention of every executive, although a number of pages are devoted to extremely detailed data concerning physical examination standards, etc., and will interest only the active medical worker.

Some of the most interesting paragraphs relate to the function of the physician in industry. After discussing the gradual development of medical work in industry, the bulletin says of the modern industrial physician: "The physician who confines his activities to the four walls of the plant dispensary is found to be of but limited value to the industry with which he is associated. It is only as his influence reaches out into the operating departments that his full possibility of service is realized." Some of the chief functions of the plant physician discussed are as follows:

1. Curative and preventive activities. This is simply the work that every plant doctor does.
2. Seeing to it that only men physically qualified for certain kinds of work are placed and allowed to continue in that work.
3. Physical examination of workers.
4. Place employees in work for which they are best fitted from physical standpoint.
5. Study the degree of hazard in different production operations and suggest protective measures to meet each situation.
6. Care of health of executives.
7. Care of hygienic conditions about the plant; such matters as proper lighting, heating, ventilation, toilet facilities, fatigue work, etc.
8. Assist in proper adjustment of disturbing factors in home life of employees.

This is a summary of the chief factors discussed in this connection. Many persons will differ with some of the conclusions arrived at, as well as with some of the functions included in the list. The discussion is interesting, however, as much to bring out points of difference as to provide information and instruction.

Other factors discussed include statistics concerning the extent and character of health supervision activities in a large number of New England industries, proper methods of staff organization for the medical department, the equipment necessary to meet ordinary plant dispensary needs, methods and types of first-aid work, uses and methods of making physical examinations of employees and the value of medical records. The entire pamphlet is well worth attention, although certain minor points may meet with considerable question.

ACCORDING to one authority about 75 per cent of the gasoline produced in the United States is obtained by direct distillation from the crude. About 10 per cent comes from natural and casinghead gas, while only 15 per cent is produced by cracking processes.

Secretary Hoover's Attitude

THE recent meeting between Secretary of Commerce Hoover and the committee representing the automotive industry was doubtless much like the similar conferences that had preceded it. The manufacturers present were frankly doubtful when they entered the meeting. They left with the firm conviction that Mr. Hoover had no other idea than to help business in any and every way possible. Also the visitors left the conference convinced that Mr. Hoover well understood the broad fundamentals of business.

It was something new to the automotive manufacturers to have it called to their attention that their business status was of vital interest to other industries. At first the members of the committee were exceedingly cautious in promising figures. After Mr. Hoover had made it clear that he personally was not at all curious about these figures; that he was interested in them only as they contributed to the general picture of business, the manufacturers got a better grasp of his plans and came forward with an offer to contribute their part to this general picture.

It was especially interesting to hear Mr. Hoover say that he did not desire to force any figures from any industry. He wanted all figures to come to him voluntarily. This attitude has done much to disarm those who have been in doubt as to his real object in gathering business data.

Need for Simple Tests of Lubricants

AT the recent meeting of the Society of Automotive Engineers one point emphasized was the need for simple tests calculated to determine the value of lubricants. A large proportion of the oils used in motor vehicles to-day are sold through garages and service stations, most of which have only the haziest notion about the real value of the lubricants they buy and sell. It would seem that simple apparatus for measuring viscosity and determining the presence by means of emulsion tests or otherwise of sulphur compounds could be readily devised, and with advantage to all concerned be placed in the hands of oil retailers, if not of the actual consumer.

There are, of course, other tests for lubricants which can be made only by trained laboratory men, but the foregoing tests are not so difficult to perform, providing a simple and inexpensive apparatus were available, with sufficient accuracy to give a reasonably fair test that would exclude or relegate to their proper place some of the poorer grades.

In many other lines enlightened advertising and selling policies have been employed to acquaint consumers with the real merits of the products they buy. Far too little has been done in this direction by oil producers with the result that the public as well as the engineer who knows more or less about lubricants distrusts the vendor. Unfortunately purchase by brand rarely assures uniformity in the lubricant, while even very large wholesale purchasers are without means for making intelligent selection of brands in the first instance. The whole situation is one which demands study and intelligent education. We believe that such education should be furnished by motor vehicle manufacturers if it is not forthcoming from the oil producer. Whoever undertakes it conscientiously will, we believe, benefit thereby.

Enlightened Self-Interest

AN automobile plant would not consciously increase the cost of parts which it buys on the outside unless there were some distinct advantage to be gained. It naturally desires to get those parts as cheaply as is consistent with the quality desired. Yet a too rigorous inspection of unimportant parts of pieces, especially if suddenly enforced, may have just that effect. Intelligence as well as rule is essential to efficient inspection work.

A parts maker said the other day that one firm had rejected a number of the parts which he was supplying that would undoubtedly have been used had they been made in the firm's own shop. This parts

maker believes that the manufacturer often rejects purchased pieces because he feels that it costs him nothing. In the case of parts produced within the manufacturer's plant, however, the manufacturer realizes directly the loss involved. He loses just the same in dealing with outside firms, nevertheless, since these firms naturally take these things into account when quoting on the next order.

In the case under discussion the rejected pieces were not defective in any essential way. Many were rejected because of slight abrasions on unexposed surfaces. To produce them without these slight abrasions and similar unimportant defects would have cost nearly double the price quoted.

In the same way, lack of knowledge on the part of the design engineer regarding practice in related industries may cause increased costs.

Both of these situations indicate the benefits that might be derived from a closer co-operation between manufacturers and contributory industries. The question is not one of lowering inspection standards; that would be undesirable. It is, rather, a matter of understanding the interdependent nature of the units of modern industry and of utilizing more fully the possibilities of enlightened self-interest.

Relation of Roads to Vehicles

ONE of the speakers at the Highway Transport Session of the S. A. E. Summer meeting dwelt on the inter-relation between the character of the roads in any locality and the general demand for automotive vehicles. His reasoning was absolutely sound, but when he proceeded to illustrate the point made by a specific example he was rather unfortunate in his choice. He said that on the Pacific Coast, where the roads in general are quite excellent, the sales of automobiles during recent months had been fair, whereas in Iowa, the poor roads of which state were well known, the automobile business had been flat.

We presume that the statements as to business conditions in the two districts are based on reports of dealers and have no reason to doubt their correctness. But when the speaker ascribed the mildness of the slump on the Pacific Coast to the good roads and its severity in Iowa to the bad roads of that State, he certainly was not very logical. It is known that Iowa for a number of years has been the banner automobile State, and if we take a period of three or four years previous to Jan. 1 last, Iowa bought more automobiles in proportion to its population than almost any other State. The roads in Iowa were no better during that period than they are to-day. This would even seem to disprove the contention that good roads influence the sale of automobiles favorably, but it does not. The point is that good roads are only one of several factors affecting demand for vehicles.

The check to automobile sales in Iowa is not particularly hard to explain. According to the latest available statistics, the State had one automobile to every 5.5 of the population, an equipment with which it ought to be able to worry along for some time in case of a pinch. Now, this pinch arrived when corn dropped in price from $1.80 a bushel to 45 cents and other agricultural products almost in proportion. Corn is Iowa's chief product and this drop goes a long way toward explaining the stagnation in the automobile trade in that State.

Getting Right with the Public

IT has been particularly gratifying during the last few days to note the number of automotive manufacturing concerns that have adjusted prices to suit the temper of the possible buyers. It is high time that this price question was settled. For a long time it has been a point of discussion wherever you went. Up hill and down dale and in the parlor one heard that automobile prices had not been adjusted and "soon you can buy at a lot less money."

This topic of conversation became popular months ago, when other prices began falling. It gained volume when Ford made his first big cut. It has been an increasing topic of conversation and rumors since. Manufacturers ignored it; dealers were confused. Selling was more or less demoralized.

Now there is the gratifying movement on the part of the manufacturers to end this price discussion. Most manufacturers have cut their prices and those who have not are explaining in their advertising why they will not cut. If the manufacturers will justify their prices, end the demoralization and get busy on a settled program, there is no reason why the motor car business should not go forward with a rush.

Scavenging and Charge Dilution with Exhaust Gases

IN the early days of the gas engine considerable attention was given to the principle of complete scavenging, and many engines embodying this principle were built. The aim then was—as it is now to a certain extent—to get the greatest possible power from an engine of given cylinder dimensions, and it was obvious that if the compression chamber could be completely swept clear of spent gases, so that the cylinder contained nothing but fresh charge at the end of the suction stroke, an increase in power could be obtained. With no change in the compression ratio, the effective ratio of expansion was decreased and a lessening in fuel economy might be looked for.

Complete scavenging has never found any application in the automotive field, no doubt because the apparatus required is too heavy and cumbersome to make it practical. On the other hand, some designers have recently even resorted to the opposite practice of introducing into the combustion chamber more dead gas than naturally remains there from one stroke to another. This reversal in practice is largely due to a change in the character of fuel employed, our present fuel having a much greater tendency to detonate than the gasoline of the earlier days. It may also be ascribed to a greater appreciation of the value of an adequate compression pressure. An admixture of spent gases with the fresh charge tends to prevent detonation and thus permits of higher compression being used, with consequent gain in economy.

Ford Makes Second Slash in Prices

Before War Basis Now Within Reach

Chassis $12 Higher Than in 1917 —Truck at $495 Is $105 Cheaper

DETROIT, June 7—Another cut in prices was announced to-day by the Ford Motor Co. It is effective immediately. The reductions are not nearly as large as those last fall which started the automobile price decline, but they mark a considerable step toward bringing Ford models back to the levels which prevailed before the war. The cuts range from $15 on the stripped chassis to $50 on the coupe and truck. The following table shows the changes:

CARS	Old Price	New Price
Chassis	$360	$345
Roadster	395	370
Roadster, with electric starter	465	465
Touring	440	415
Touring, with electric starter	510	510
Sedan (starting system and demountable rims)	795	760
Coupe (starting system and demountable rims)	745	695
TRUCKS		
Chassis	545	495

The following statement was made in announcing the price cut:

"The big reductions last fall were made in anticipation of lower raw material costs of which we are now getting the benefit, and this fact, together with increased manufacturing efficiency and an unprecedented demand for Ford cars, particularly during the last three months, permitting maximum production, have made possible another price reduction immediately.

Sales at Highest Point

"Ford business in April and May was greater by 56,633 cars and trucks than for the same two months last year. In fact the demand was even greater than the supply, so that output has been limited, not by unfilled orders, but by manufacturing facilities. During May we produced 101,500 cars for sale in the United States alone, making it the biggest month in the history of our company and our factories and assembly plants now are working on a 4000 car daily schedule for June.

"The Fordson tractor still is being sold at less than the cost of production on account of the recent big price reduction and it is impossible therefore to make any other cut in the price.

The announcement also was made that the wages of Ford workmen will not be reduced as the result of the price cut.

While the latest Ford cut was not so unexpected as that made last fall, other manufacturers had not expected price readjustments for a month or two yet.

In supplementing the statement in connection with the price cuts and denying reports that the plant will close, Henry Ford said:

"It has been the custom of the plant to release men during harvest time so grain could be cared for, but since there is an abundance of farm hands this year, this will not be necessary."

Ford said the plant was running far behind orders and that he expected to keep up the present production schedules indefinitely.

The Ford Motor Co. of Canada has announced a price cut of $65 on open cars and roadsters and $110 on closed cars. This makes the price of the touring car, without starter, $710.

TABLE SHOWING RANGE OF PRICES ON FORD

	Aug. 1 1917	Sept. 21 1917	Oct. 16 1917	Feb. 25 1918	Aug. 16 1918	Mar. 4 1920	Sept. 21 1920	June 7 1921
Touring	360	365	365	450	525	575	440	415
Roadster	345	350	350	435	500	550	395	370
Chassis	333	338	338	400	475	525	360	345
Coupelet	505	510	560	560	650	...	...	...
Coupe	...	...	...	...	...	*850	*745	695
Town Car	595	600	640	640	...	...	...	...
Sedan	645	650	695	695	775	*975	*795	760
Truck	600	600	600	600	550	600	545	495

*Includes starter and demountable rims.

Paige Reduces Prices on Complete Line

DETROIT, June 7—Price reductions were announced to-day by the Paige-Detroit Motor Car Co. They have been expected for several days. The reductions range from $20 to $160. The following table shows the new and old prices on the various models:

	Old Price	New Price
Glenbrook touring car	$1795	$1635
Ardmore Sport	2015	1925
Lenox Roadster, 2 passenger	1795	1635
Four passenger Coupe	2600	2450
Sedan	2720	2570
Lakewood, 7 passenger touring	2895	2875
Larchmont Sport	2995	2975
Five passenger Coupe	3775	3755
Seven passenger Sedan	3850	3820
Limousine	4060	4030

Price Changes Continued on Page 1233

Price Fluctuations Hold May Sales Low

Buying in New York District Spasmodic During Changes —Dealers Prosperous

NEW YORK, June 4—The automobile market in the Metropolitan territory is feeling keenly the swift succession of price reductions and sales are below standard on practically all lines, even including some of those which cut a month ago. With each succeeding reduction, the distributor handling the car reduced has a spurt of sales lasting a week or two, when somebody else comes along with a reduction and gets the attention of the public and some of its money, for the time being.

As a result of these reductions, sales for May, when they are fully compiled, apparently will show a smaller total than for April. One well known line sold a few less than half as many cars in May as in April and a good many others, except those which have benefited by heavy reductions, have had similar experiences.

Sales Surpass Former Years

However, the majority of distributors are making money. One large house which had May sales running something like 50 per cent of those of April, still made a profit in May, which the distributor declared "would have tickled me to death five years ago." He made a point that profits of the past two years are being continually used as a basis of comparison by dealers who are having about as much trouble as business in general in getting back to normal.

The Row presents a striking, if not an attractive, appearance, with a large number of salesrooms bearing flaring cloth signs announcing price reductions.

The used car situation is rather chaotic because of frequent reductions made necessary by reductions in new car prices, but the demand is fully as good as for new cars.

Caution Marks June Factory Plans

Parts Makers Find Trade Outlook Poor

Price Revisions Keep Cars Moving—Five Companies to Increase Output

NEW YORK, June 7—A large part of the automotive industry is starting June with no very definite idea of its destination. On the surface, at least, conditions are more uncertain than they have been at any time since January. Forecasts of production for the month are extremely hazardous.

Manufacturers of parts and accessories, whose plants have been operating for two months on an approximate 50 per cent basis, have less business booked for June than for any month since February. Many releases which were given in May for this month have been countermanded and there are few reports of new business.

It is difficult to reconcile this authoritative statement of conditions among the parts manufacturers with largely increased sales in passenger car lines which have made substantial price cuts. The companies which have made price readjustments assert without exception that largely increased sales followed their announcements and investigation shows there is no reason to doubt the truth of this statement.

Since retail sales of automobiles are increasing while the business of parts manufacturers is at a standstill, the only explanation is that most companies had accumulated a considerable surplus of cars which must be liquidated before production is resumed on the scale which prevailed in April and May. There is every indication, on the other hand, that retail sales for June will equal or exceed those of May, which averaged probably 25 per cent less than for April. Reports to the National Automobile Chamber of Commerce showed a gain for May of 13 per cent over April.

July Shutdown Unlikely

Detroit is pessimistic over the outlook for the immediate future, but it is not at all unlikely manufacturers there will be more cheerful before the close of the month. There is much talk in Michigan of a general shut down in the industry July 1, but unless retail sales conditions become much worse than they are now as June progresses, there is little probability of such drastic action being taken. At the present rate of sales in most lines the present surplus soon will be absorbed and factory operations then will be expanded.

Analysis of the situation does not indicate that it is as black as it is painted in Detroit. Nearly all the large production companies have taken their stand on prices and the situation in this respect is more stable than it has been in some time. Prospective buyers can go into the market with a reasonable certainty that there will be no more cuts for several months to come in the lines which have announced their attitude.

NEXT NEW YORK SHOW AT MADISON SQUARE

NEW YORK, June 3—The members of the National Automobile Chamber of Commerce at their annual meeting here yesterday decided to hold the next New York Automobile Show in Madison Square Garden because the Grand Central Palace is no longer available for such expositions. Arrangements will be made whereby there will be space at the Garden for exhibits by all members.

It was the unanimous belief that every effort should be exerted to make the show next January one of the most successful ever held. One of the leading factors in the selection of the Garden was its central location, making it more readily accessible in this respect, which is more desirable than the Palace.

The Chicago show will be held in the Coliseum as usual.

Ford Leads Factories in Schedules for June

DETROIT, June 6—Definite production schedules for June have been fixed by only seven automobile factories in Michigan and in only five of these are increases planned over May output. Ford is going over 100,000 for June while Lincoln, which built 425 in May, will cut to 400 this month. Both Cadillac and Packard announce increased June schedules, while Chevrolet will step up about 1400 if the schedule is maintained, and Studebaker approximately 1000. June estimates in those plants are 4400 and 8335 respectively. Packard plans to build 1000 single sixes and Cadillac announces 1600 against 1400 in May.

Dodge Brothers officials declined to say what schedule would be maintained as to working days beyond the statement that they expected to continue on an uninterrupted daily schedule hereafter.

All executives are disposed to move cautiously as regards production, and it is evident, save in those factories announcing definite schedules that the out-

Price Cooperation Promised by Makers

Recognize Need for Quick Stabilization of Market—To Study Truck Dumping

NEW YORK, June 3—Real appreciation of the need of immediate action on whatever price adjustments are to be made was displayed by the members of the National Automobile Chamber of Commerce at their annual meeting here yesterday. It was felt that price changes might better have been made two months earlier or two months later but since they have been begun, manufacturers owe it to their dealers and to the public to take a definite stand which will aid in stabilizing the situation. Desire of bankers for further liquidation was blamed in some quarters for precipitation of readjustments in the automotive field which has been more prosperous than almost any line for the past four months.

The N. A. C. C. received a telegram from Harry G. Moock, general manager of the National Automobile Dealers' Association, urging on behalf of the dealers that car makers decide at once whether or not they intend to change their prices. A reply was sent stating that the N. A. C. C. was in entire accord with this view of the situation and felt the warmest sympathy for the dealers in the difficulties they are having to face.

Reports on retail business conditions in all sections of the country were submitted to the members. They showed that there was a decline in sales in May over April i almost every district except the South, where there was some improvement for the first time in many months. The best showing was made by lines which had reduced prices.

Expect Drop in June

It was the general opinion that June business would not equal that of May but that it would be of substantial proportions and that there was no occasion for pessimism.

Little change was reported in the commercial vehicle division of the industry. A few companies are doing a good business and some others have slightly increased their production. Reports are coming from dealers with increasing frequency, especially in the Metropolitan district, that they are finding great difficulty in competing with persons selling American made trucks of high grade reimported from England and France. Service on these vehicles is guaranteed and they are put on the market for 50 per cent of their list price. The Fiat

Durant Speeds Up Production Plans

Experimental "Four" to Sell Under $900 Pleases Engineers—To Have Four Lines

NEW YORK, June 7—Important announcements by W. C. Durant regarding the future of Durant Motors, Inc., are expected in the near future. They will relate not only to production and personnel but to finances.

Plans for production are rapidly taking form. The experimental Durant cars have been completed and are satisfactory to the engineers in every respect. The "Four," which will sell for less than $900, is reported by those who have seen it to be a high grade job. It has many refinements not found ordinarily in low priced cars.

Provision now has been made for three lines. One of them will be the Durant, another the Collins, which will be produced in the old Cadillac factory in Detroit, and the third the Sheridan. A fourth line will be added, it is understood. Durant promised the people of Flint, Mich., in January, that one of his plants would be located in that city. He will keep his word in this respect and it is expected the fourth division of his company will be located there. Chassis models will be limited under the present plans, but there will be several body models. The Sheridan will be converted into a six-cylinder job and the Collins will be an eight.

Preliminary steps for the building up of a dealer organization now are being taken and it is understood several contracts already have been signed. It probably will be the policy of Durant Motors, Inc., to have its dealers handle all the affiliated lines. In this respect its program will differ from that of General Motors.

Michigan Gives Approval to Durant Stock Sale

DETROIT, June 6—Stock of Durant Motors, Inc., has been admitted to the Detroit Stock Exchange following approval by the Michigan Securities Commission and authorization for sale of 200,000 shares of common. Authorization was for sale at a price to be governed by market quotations and the stock now is listed on the exchange at 22 7/8. The company, under the commission order, is allowed to sell stock for cash or upon reliable payment plan on application to commission.

The officers are W. C. Durant, president; Carroll Downes, vice-president; Harry F. Hebermann, secretary, and W. W. Murphy, treasurer. These with E. Healy of New York compose the directorate of the company, incorporated under Delaware laws with offices in New York and Flint, Mich. The stock issue is asked to secure working capital and the declaration recites that the business of the company will be to manufacture automobiles, trucks, parts and accessories, and to hold securities of allied and affiliated companies. In the application for listing on the exchange, the company declares it has authorized 1,000,000 shares of no par value common stock of which 507,057 shares were outstanding May 1.

Poertner Gets Durant in New York Territory

NEW YORK, June 6—The Poertner Motor Car Co., distributor in the New York territory of the National and Scripps-Booth, has been appointed distributor in the Metropolitan area for Durant Motors, Inc. Poertner, who is one of the veterans in the automobile business, has had the National Scripps-Booth for several years, his territory including New York City and parts of New Jersey and Connecticut. He was formerly president of the New York Automobile Dealers Association.

It is learned that the Durant will probably sell for $890. It will have a four cylinder overhead valve engine and will be particularly well appointed, it is said, for a car of its price. At the start there will be three models, touring car, sedan and coupé.

G. M. Truck Resumes on Full Time Schedule

DETROIT, June 6—All departments of the General Motors Truck Co. resumed operations to-day and a full time schedule will be maintained indefinitely, according to W. L. Day, general manager. The fact that the machine shop and assembly department were down last week gave rise to a report that the plant would be closed entirely.

"We got ahead a bit on production, but the report that we closed down or would close was wrong," said Day. "We held up work in the machine shop and assembly for a week, but other departments were going right along and the plant opened in all departments to-day."

Day said the company had been having good business throughout the spring until the middle of May when there was a noticeable slump. This, however, he declared, he thought would be only temporary and looked for a gradual increase during the summer.

AMERICAN BUSHING SPEEDS UP

DETROIT, June 6—The American Bushing Corp. of Marysville, Mich., which is manufacturing bushings for the American and Canadian Ford companies, has increased production to 20,000 daily. Important changes in production methods devised by President J. W. Leighton permit the production increase.

MINNEAPOLIS S. A. E. ELECTS

MINNEAPOLIS, June 6—The Minneapolis section of the S. A. E. has elected officers as follows: President, W. G. Clark; vice-president, C. E. Moody; secretary, C. T. Stevens; treasurer, J. S. Clapper.

Cleveland Industry Shows Further Gain

Increased Employment 3.6 Per Cent in May—Other Businesses Report Additions

CLEVELAND, June 3—The automobile industry in Cleveland continued on the up-grade during the month of May according to a survey made by the Committee on Labor Relations of the Cleveland Chamber of Commerce for the U. S. Department of Labor.

The twelve companies in the automobile industry in this city were surveyed and the number of employees on the payrolls of the companies May 30 was 3.6 per cent greater than the record for April 30. On April 30 these companies employed 9949 persons, while on May 30 the number had increased to 10,310.

These reports have been issued by the Committee on Labor Relations since the first of the year and the automobile industry sets the pace for all other industries in the matter of recovery. The report discloses that general conditions in Cleveland are improving for ninety-nine establishments that were surveyed had increased the number of employees May 30 over April 30 1.8 per cent. The total number of employees on May 30 was 62,956 as compared to 61,847 a month ago.

The building trades workers have been on a strike here for a month and there was a decrease of 43.8 per cent in the number of employees in this industry in the last month. Metal products other than iron and steel made a big advance toward normal conditions in the last month with an increase of 14.1 per cent in the number of employees. The automobile industry is held responsible largely for this increase.

The other increases reported are as follows: Food and kindred products, 7 per cent; textiles and their products, 5.2 per cent; iron and steel and their products, 4.6 per cent; paper and printing, 5.8 per cent; chemicals and allied products, 2.7 per cent.

COURT ORDERS JOHNSON SALE

INDIANAPOLIS, June 3—Authority was given recently by the St. Joseph Superior Court for the sale of the Johnson Motor Wheel Co. of South Bend, Ind. Following financial difficulties the company was placed in the hands of a receiver. The company conducted a stock selling campaign a short time ago and hundreds of persons in the northern part of the State invested their savings.

KNOX PROPERTY REVERTS

SPRINGFIELD, MASS., June 4—Knox Motors property which has been occupied by the Sinclair Motors Co. has reverted to the Knox Motors interests under a mortgagee's sale of the real estate. The property was bid in for $250,000 by H. G. Fisk, president of Knox Motors.

Toledo Factories Increase Schedules

Overland to Double Production in June—Parts Plants Gain Steadily

TOLEDO, June 6—A substantial improvement in the automobile industry is shown in the announcement of June schedules by several factories here.

Willys-Overland output this month will be more than doubled, with enough orders already received to take up the whole month's production. The notice was sent out Saturday that no closed car models could be delivered now before June 20. The price cut has greatly stimulated the business.

The production of automobile equipment at the plant of the Electric Auto-Lite Corp. will be increased by 20 per cent in June, Clement O. Miniger, president, announced. The May production at the plant was 20 per cent greater than in April. There are now 1027 employees at the Auto-Lite plant, which compares favorably with a normal force of about 3000.

President Miniger says that orders received during the last week from many companies which have cut prices on their cars shows that the lowering costs are stimulating business beyond the expectations of the manufacturers. He doesn't expect the usual summer sag to come this year at all.

George D. Moore, general manager of the Toledo Chevrolet plant, said that nearly 200 employees had been brought back into the plant here in the last week and that the force is to be doubled this week. This is largely on the strength of the increased volume of business which Chevrolet distributors have noticed since the announcement of price reductions.

The Chevrolet company manufactures only differentials and transmissions here. The company has had a large stock of these parts on hand in various of its assembling plants and in the hands of agents so that necessarily the local plant has not been speeded up as much as the actual production would indicate.

There were nearly 1200 employees at work in the Chevrolet plant here in the peak periods.

Daily Driveaways 100 to 150

The daily drive-aways of 100 to 150 cars from the Overland plant has recalled to many of the employees the prewar days. There are also many carloads leaving the city by rail every day to more distant points of distribution. Several boatloads have gone to Buffalo in the last few weeks for the eastern States' demands.

The June production is to be at its maximum speed by June 10, according to Vice-President Charles B. Wilson, at the plant here. He says the actual output of cars for June is to be 112 per cent over the number produced in May. The plant payroll will be increased by about one-third so that there will be 8500 employees at work the last week in June.

One of the most difficult problems for the factory to face at the present time is the task of getting the materials delivered here in time to keep up with production. Supplies have been coming so slowly for several months that in many cases it is difficult to get the necessary speed up in short notice.

The factory has also gone into full time operation. For several weeks it has been on a four-day week basis, but now the output of every man every day is needed to keep up with the orders. The employment office here has indicated that practically every old Overland employee who could be located has been recalled into the service of the company and that from now on the positions will be open for new men.

Northway Pushes Sales in Eastern Territory

BOSTON, June 4—Northway Motors Sales Co. has launched an active truck merchandising campaign in the territory covered by its thirteen factory branches in New England and Middle Atlantic States. Fifty new salesmen have been placed in the field who will operate under the new sales organization headed by Joseph Husson, general sales and advertising manager, formerly editor of The Commercial Vehicle. His associates are W. E. Downs, assistant sales manager; H. F. Flugge, general service manager; F. L. Ortla, assistant service manager; R. B. Sill, branch sales manager; H. W. Pierce, manager of dealer sales, and Richard A. Magee, who is in direc charge of advertising.

Springfield Body Adds Unit to Meet New Sales

SPRINGFIELD, MASS., June 3—Plant capacity of the Smith-Springfield Body Co. is to be increased 50 per cent and 100 additional men are to be employed. Construction of a new unit, 90 x 320 ft., was begun four weeks ago and will be completed June 15. Completion of this building will double the size of the plant.

The company has recently obtained contracts for closed-car construction from the Wills Sainte-Claire and Mercedes companies. It has been making closed and touring type bodies for Rolls-Royce of America, Inc., Stevens Duryea, Marmon, Lincoln and the Citroen company.

TEXAS BUSINESS IMPROVED

DETROIT, June 6—Walter Zimmermann, special representative of Olds Motor Works, Lansing, has returned from an extended trip to the cotton states with the report that business conditions are greatly improved in some sections of the South. This is true particularly in Texas, Zimmermann said. With more stable government in Mexico that country is beginning to buy in Texas and cotton growers are optimistic.

Oakland Officials Resign Positions

Masten, Young and Hamilton Leave and May Join Durant —Other Changes

DETROIT, June 4—Changes in personnel have been coming with increasing frequency within the last two or three days, prominent among which was the departure of W. H. Masten and J. W. Young, assistants to the general manager of the Oakland Motor Car Co. and A. G. Hamilton, chief engineer, whose resignations became effective May 31. No successors have been named to Masten's or Young's positions by General Manager G. H. Hannum, but Benjamin Jerome, formerly assistant to Hamilton, succeeds to the position of chief engineer.

Masten had been with Oakland a long time and was regarded as one of the leading figures in the organization. No information regarding the plans of any of the three officials could be ascertained, though persistent reports are that they will join W. C. Durant, R. H. Collins and Edward Ver Linden in the new Durant organization.

Announcement of resignations of Frank G. Eastman, advertising manager of the Lincoln Motor Co. and H. S. Dart, advertising manager of the Paige Motor Car Co., both of which became effective within the last two days created much surprise in local automotive circles. Dart and Eastman were regarded as firmly entrenched and were considered among the leaders in that branch of the business. Their resignation came suddenly, and no information regarding the details could be secured either from factory officials or from Dart or Eastman.

Dart will be succeeded by W. K. Towers, at present advertising manager of the Reo Motor Car Co. Towers will assume his duties with Paige June 13, but no successor to Towers has been named by Reo. Dart has several connections under contemplation but is not yet ready to make an announcement. Officials of the Lincoln Motor Co. have announced no successor to Eastman and the latter has made no future plans.

H. M. Chadwick, formerly sales manager of the Insulating Materials Co. of Detroit, and prior to that with the Packard Motor Car Co. has taken over the sales and advertising end of the Michigan Crown Fender Co. products. The Crown Fender factory is located at Ypsilanti and manufactures fenders and other automobile parts.

IMMEL STOCKHOLDERS TO BID

COLUMBUS, June 6—While no definite date for the sale of the plant and other assets of the Immel Co. has been set it is announced it will be within the next 40 days. Receiver R. H. Schryver has been authorized by the court to sell the plant and all of the assets. A committee of preferred stockholders is being organized to bid on the plant.

Buying Power Large Says Reserve Head

Financial Situation Reaches New Strength—Anxious to Aid Legitimate Business

NEW YORK, June 3—"The emergency of 1920 has definitely passed," said W. P. G. Harding, Governor of the Federal Reserve System, speaking before the annual meeting of the National Automobile Chamber of Commerce yesterday. "There is nothing as far as the financial condition of the country is concerned as affected by the Federal Reserve Banks that causes any other feeling than one of optimism."

Availability of credit, the fact that automobile shipments for the past two months equalled 67 per cent of the same months of last year, the feeling that prices have reached a new stable level, and Governor Harding's statement that "the public has a great deal of buying power left" were major points of the meeting.

Governor Harding pointed out that the financial situation of the Federal Reserve system is stronger than at any time since the third Liberty Loan and that the banks are anxious to lend to legitimate business.

"We want to get the public out of the idea that things are constantly going lower and lower and lower," said Governor Harding, "and we should get some stability into the situation." It was the opinion at the meeting that the new low price levels now reached would probably be stabilized on the present basis as almost all the motor companies have readjusted their prices. The consensus of opinion brought out that motor car and truck companies have anticipated the lower levels of raw materials and have priced their product on the new basis.

Cars Keep Steel Moving

"The public has a great deal of buying power left," said Governor Harding, "and buying power begets buying power. You start up one industry and you automatically start up another. It is amazing when you consider the automobile industry to find how many things are dependent upon its prosperity. It affects the purchases of steel and all the processes of steel manufacture. See how much employment that gives to labor."

The automobile market is a leader in return of buying, reports at the meeting brought out. The May shipments exceeded April by 13 per cent and April and May shipments were 67 per cent of the same months of last year, comparing favorably with the steel market, with pig iron which is on a 50 per cent basis, and with rail transportation which is on a 60 per cent basis.

"The Federal Reserve Banks," said Governor Harding, "which are the ultimate resource of all member banks, and through them, of the public are in a position now better than ever before to extend to all legitimate business all assistance needed and are not only in position to do that but are anxious for business to avail itself of it.

"The Federal Reserve System has no desire other than to be a help to business, and all paper which is eligible under the Federal Reserve Act—that is notes, drafts and bills of exchange issued or drawn for commercial, agricultural or industrial purposes—is eligible for rediscount at any Federal Reserve Bank upon the endorsement of a member bank. There are no discriminations in the Federal Reserve System against any class of paper which is eligible and all applications for rediscount will be considered in a businesslike way upon their merits."

Central Ohio Finds Sales Outlook Better

COLUMBUS, June 6—With more price reductions announced and a better feeling developing in industrial circles, the sale of automobiles in Columbus and central Ohio territory is gradually increasing. This is the statement of practically all of the Columbus agents and also from some in the territory immediately surrounding the Buckeye Capital. The passenger car business is especially stronger, although some increase in demand is reported for commercial vehicles.

Farming communities are showing an increase in the demand for passenger cars. This is seen in the corn raising sections when the crops are now planted and farmers have a little time to look around. There are excellent prospects for a big wheat crop and this has the effect of stimulating sales of cars. In the farming sections there is also an increase in the demand for trucks and small tractors.

TIMBER SUPPLY PLENTIFUL

DETROIT, June 6—Emil Brock of Weis-Lesh Mfg. Co. of Memphis, Tenn., logging and spoke manufacturing unit of the Motor Wheel Corp., declares there is a timber supply sufficient for the next 50 years under control of his organization. Brock has been in Lansing for a conference with H. F. Harper, general manager of the Wheel Corp., and other officials. He said the Memphis unit has a large supply of raw material for shipment to the wheel plant in Lansing. The mills, however, are running on a curtailed production schedule.

MUTUAL INSURANCE URGED

NEW YORK, June 3—Increases in automobile insurance rates during the past few months have again directed the attention of automobile manufacturers and dealers to the need for a mutual insurance company to care for motor cars and motor trucks, similar to the one launched four years ago. It is asserted by the National Automobile Chamber of Commerce that loose methods of accepting risks without due regard to the moral hazard and excessive overhead expenses have resulted in the imposition of rates from which the only relief lies in mutual companies.

Harding Visit Stirs Kansas City Action

Dealers Line Up Sources of Credit—Southwest Nearing Normal Buying Move

KANSAS CITY, June 6—The visit of Governor Harding of the Federal Reserve Board, and the announcement of relaxation of restrictions as to rediscounting, which followed that visit, are beginning to show results in Kansas City territory. The immediate results are rather the sifting out of bankers, than the promotion of motor car sales.

Motor car dealers are no longer put off with the defense against loans, that the Federal Reserve will not rediscount the paper. Since the bankers have to give the real reasons for refusal, the motor car dealers are better able to judge what their next step should be. In some cases, this step is the finding of another banker. The motor car dealer who has his books in good shape, whatever they show, can confidently visit another banker and talk with him.

It is evident that many banks have not reached the satisfactory condition in relation of loans to reserves, of the Federal Reserve Banks. It is said that the country banks are less able to extend credit facilities than some of the larger city banks—the liquidation of the past few months being heavier with the city banks, whereas the country banker still has to carry agricultural loans. But the activity of the motor car dealers in ascertaining facts, is equalizing the service, so that the banks that can extend facilities will have opportunity to do so.

Perhaps the most important result of the visit of Governor Harding has been in the stiffening of the morale of the dealer. He now has the courage of his industry. Gradually this brighter tone is being infused into the territory, into bankers, and business men, as well as into the dealers themselves.

Trade Trip Dispels Gloom

Another incident that has helped mightily to bolster the optimism of Kansas Citians is the trade trip of the Chamber of Commerce through Kansas, Oklahoma, Texas, Arkansas and Missouri. The hundred Kansas Citians started on the trip dubiously, fearing to be deadly depressed by the sad condition of the Southwest and the lugubriousness of its business men. But they found that the Southwest is recovering.

"There is business in the Southwest waiting for us to go after it," said one of the men who made the trip. "The trouble with us is that we have listened to the gloomy stories of our travelers who have been convinced by the refusal of merchants to 'buy now,' and who have assumed that the merchants were never going to buy. The Southwest is past the turn, and is going strong. Stocks are reduced and merchants will be in the market close to normal very soon."

Commonwealth Sells Car Finance Business

Commercial Investment Trust Takes Over Clientele and Paper Now on Books

NEW YORK, June 7—The Commercial Investment Trust, 347 Madison Avenue, New York City, has acquired the automobile business of the Commonwealth Finance Corp. Under the arrangement the C. I. T. has taken over automobile paper on the books of the Commonwealth. In addition to acquiring business already on the books, the C. I. T. will continue to serve Commonwealth clients. Samuel S. Mattison, former sales manager of Commonwealth, has accepted a similar position with the C. I. T. and will have with him as district managers, B. J. Hall, Baltimore territory; W. W. Thomas, Buffalo territory; Elmer P. Yost, Pittsburgh territory; J. E. Parker, Philadelphia territory; W. H. Billings, Boston territory, and W. A. Gilroy and M. R. Sanborne in the New York and New Jersey territory. The Commonwealth company will transfer its activities to other fields in which its broad charter permits it to operate. It already has taken up real estate and mortgages, not so much in the metropolitan district as in other places. Its plans in this direction have not been definitely worked out.

The assets of the corporation have been transferred from the original South Dakota corporation to a new corporation formed in Delaware. This action was approved, it is stated, by approximately 90 per cent of the stockholders. The litigation which has kept the affairs of the corporation in the courts for the past two years has been settled and all the suits have been withdrawn. It is understood as a preliminary to discontinuance of the suits a substantial sum was paid to Ormsby McHarg and his associates by Henry D. Tudor, president of the company, and the faction which has stood with him in the controversy.

Tudor and his friends never lost control of the affairs of the Commonwealth and the receivers appointed both in South Dakota and in New York never obtained possession of the assets. They were successfully barred out by a series of restraining orders.

TIRE SERVICE CHARGE URGED

NEW YORK, June 4—The executive committee of the tire manufacturers division of the Rubber Association of America has recommended to all members that a service charge based upon a percentage of the invoice cost of the returned goods, plus return freight charges, be charged all purchasers who return tires and accessories to manufacturers for repairs. This custom on the part of motor car owners has given rise to many difficulties and it has been deemed advisable to handle the business in a uniform way.

The publicity department of the Rubber Association will devote considerable attention to educational work covering load carrying capacities of pneumatic truck tires. The attention of truck manufacturers and users will be called to the fact that the load carrying capacities specified in the schedule of maximum loads are the actual maximums and that in respect to overloading, consideration should be given to the necessity for a factor of safety by the use of larger equipment.

Would Liquidate Stocks Stored in South America

NEW YORK, June 4—Proposals for the formation of a co-operative liquidating corporation to handle all excess stocks of American merchandise unclaimed in the customs houses of South America were made to-day at a joint meeting of the Argentine-American Chamber of Commerce, Brazilian-American Chamber of Commerce, American Manufacturers' Export Association and the Pan-American Advertisers Association. The meeting was attended principally by local export managers and considered the liquidation of all classes of goods without reference to automotive lines. Estimates placed the value of these unclaimed goods at Buenos Aires as $25,000,000.

Reports from various cities in Latin-America recently received indicate that liquidation is proceeding on all automotive products and consequently there is some doubt as to the part the industry might take in the proposed corporation. Its purpose would be to clear all unclaimed goods through the customs houses so that storage penalties would not accrue, and so that they would not be auctioned off for charges. The corporation then would endeavor to market the goods in the various countries, endeavoring to do so to the best interest of all business.

The proposals were made by **Max W.** Boley of Buenos Aires, who was the delegate of the Chamber of Commerce of the United States in the Argentine, and J. W. Finch, an exporter to Brazil and Argentina. The plan will be studied by a committee composed of two members from each of the organizations participating in the meeting.

DECLARE PRACTICES UNFAIR

NEW YORK, June 6—The National Vigilance Committee of the Associated Advertising Clubs of the World has sent out a statement warning against what are characterized as unfair practices of the Franklin Tire & Rubber Co., 34 West Lake St., Chicago. It is asserted that this company, which originally called itself the Racine Tire & Rubber Co. of Chicago, solicited dealers to handle tires called "Racine quality tires." Dealers confused the Chicago company with the Racine Rubber Co. of Racine, Wis., makers of standard tires. Use of the word Racine finally was discontinued by the Franklin Co. They now offer, howver, "special racing tires."

Horsemen Belittle Tractor-Horse Test

Declare Demonstration Purely to Focus Attention on Tractors —Sanction Withheld

CHICAGO, June 6—The Horse Association of America has issued a statement asserting that it has not sanctioned the demonstration by tractors and horses in field operations which has been arranged by the National Implement & Vehicle Association. The first of these tests will be held at Fargo, N. D., June 28 to 30. The statement says use of the name of the Horse Association of America in telling of the proposed contests was unauthorized. The plan is characterized as "purely one by the tractor interests calculated to focus attention upon their national demonstrations. No horsemen have been consulted in respect to the demonstration or rules." The statement says:

"The situation is this: Tractor sales have fallen away to practically nothing, due to awakening consciousness on the part of the farmers that horses and mules furnish the most reliable, efficient and economical power on the farm, when farm profits over a period of years are taken as the test. In a desperate effort to do something to stimulate tractor sales, a group of men in charge of this particular problem have hit upon this plan in the hope that such a demonstration would show that more can be done in a few hours with tractors than with horses and thus create sentiment favorable to tractor sales."

Select Dakota Site for Tractor Trials

FARGO N. D., June 6—The Haggert 640-acre farm on the Red River road six miles west of here has been selected for the truck, roadmaking and ditching demonstrations to be made June 28-30 under the auspices of the National Tractor Farming Demonstration and Show. Chairman J. B. Bartholomew of Peoria, Ill., announces horse show in connection. E. E. Whaley is general manager. Each tractor or horse-drawn outfit will be assigned a definite section in which to work, based on the number of bottoms. The horse outfits will be in competition only with each other. Trucks will start from various points to reach the farm overland in time for the contest. They will be judged on their records to the finish.

BODY BUILDERS MEET JUNE 16

NEW YORK, June 6—A special mid-year convention of the Automobile Body Builders' Association will be held at Detroit, June 16 and 17, "to consider ways and means of overcoming the difficulties confronting the industry." Attendance will not be limited to members of the association but will be open to all manufacturers of automobile bodies.

Price Cooperation Promised by Makers

Recognize Need for Quick Stabilization of Market—To Study Truck Dumping

(*Continued from page* 1227)

company also is making a strong bid for business with its trucks.

The truck manufacturers discussed seriously the question of what could be done to make less serious the competition of reimported trucks. Some of them felt that if Congress enacted a permanent anti-dumping law which would cover the situation it would result in retaliatory action, especially by England and France, which would interfere with American sales in those countries. Others took the position that there was little probability of business with these countries for a long time to come under even the most favorable conditions.

No action on the subject was taken by the truck committee but it was decided to investigate the subject further and it was deemed advisable to attempt to have a clause inserted in the permanent tariff bill which would protect the industry from this competition.

The unit parts service question was discussed at the afternoon session. The viewpoint of parts manufacturers who have established chains of stations at which their products can be purchased was presented by E. H. Broadwell, president of the Motor and Accessory Manufacturers' Association. M. L. Pulcher, vice-president and general manager of the Federal Motor Truck Co., represented the manufacturers of assembled trucks and strongly opposed the parts makers' service plan. The dealers were not represented in the discussion and no vote was taken. There was evident a wide difference of opinion on the part of the members of the N. A. C. C. Broadwell declared the manufacturers he represented would do whatever was best for the industry.

Have Time Now for Service

One section of the manufacturers contends that conditions are different now than they were a year or two ago when owners of motor vehicles were clamoring for parts and the dealers were so busy selling cars and trucks that they paid little attention to their servicing. The situation now has changed radically and everyone is out fighting for business. It is easy to get men and materials. It was felt that a general discussion of the question would be helpful and lead to great reforms in respect to overcharges.

The tax committee reported the action it had taken at Washington in appearing before the Senate Finance Committee in opposition to the "stigma taxes" imposed on the industry. Activity on the tax question will be continued. Everyone interested is expected to make his position plain to his representatives in Congress.

A general meeting of all the interests advocating the passage of the Townsend highway bill was held Wednesday night and a program was outlined for work in advocacy of this measure. At the meeting were representatives of the N. A. C. C. the M. A. M. A., the Rubber Association of America and the N. A. D. A. Chief opposition to the Townsend bill comes from the American Federation of Farm Bureaus.

Officers and Directors Re-elected by N.A.C.C.

NEW YORK, June 3—Members of the National Automobile Chamber of Commerce at their annual meeting yesterday re-elected five directors whose terms had expired. They were: A. J. Brosseau, president of the International Motor Truck Corp., A. R. Erskine, president of the Studebaker Corp., Alvan Macauley, president of the Packard Motor Car Co., W. E. Metzger, vice-president of the Columbia Motors Co., and R. E. Olds, president Reo Motor Car Co.

At their reorganization meeting the directors re-elected the following officers: President, Charles Clifton, Pierce-Arrow Motor Car Co.; vice-president, Roy D. Chapin, Hudson Motor Car Co.; second vice-president, passenger car division, C. C. Hanch, H. C. S. Motor Car Co.; second vice-president, motor truck division, Windsor T. White, White Motor Co.; secretary, A. J. Brosseau; treasurer, H. H. Rice, Cadillac Motor Car Co.; general manager, Alfred Reeves.

Ford Leads Factories in Schedules for June

(*Continued from page* 1227)

put will be based wholly upon current sales demand. In spite of figures announced, a cereful check of all factories indicates that total production this month, exclusive of Ford, will not be more than 60 per cent of May figures.

Hupp now is building from 75 to 80 cars daily, but Hupp officials frankly admit that as soon as production equals current demand, the plant will slow up and perhaps close down temporarily until sales justify resumption. Buick officials express the hope of topping May production figures.

The Timken Detroit Axle Co. will close July 1 for one month and executives will take vacations simultaneously. Continental Motors is laying off men in its sales and other departments, indicating a general slowing up. The Liberty Starter Co. is cancelling deliveries.

PART TIME WORK GROWS

DETROIT, June 6—Employers' Association figures for the week ending May 31 show a decrease in the number of employees over the previous week of 3103 and an increase in employees working part time of 2371. Total employed was 113,456 against 116,564 the previous week. The figures are from 79 factories including practically all automobile plants.

Most Factories Take Position on Prices

N. A. D. A. Gets Replies from Fifty Manufacturers—Twenty-two Stand Pat

ST. LOUIS, June 4—Automobile manufacturers are pretty well agreed that the best way to stabilize the market is by a definite determination of price according to replies received by Harry G. Moock to his telegram May 31 to the manufacturers asking them to determine whether they were going to reduce, raise or stand pat and let the public know exactly what might be expected. Replies have been received from more than 50 manufacturers.

"I want to emphasize at this time," Moock said, "that my telegram of June 2 was not a request to manufacturers to reduce their prices. That's a matter that the factories only can determine, but the important thing which I sought to bring out in that request was that the public must be made to understand the situation. If a manufacturer is going to cut, let him cut now. If he is going to raise, let him raise. If he is going to stand pat, let him stand pat. But tell the public what you are going to do and stick to it, was the tenor of my message.

"Manufacturers who announced that they would maintain present prices are Haynes, Milburn, Rausch-Lang, Briscoe, Commonwealth, Cadillac, Maibohm, Daniels, Grant, Brewster, Pilot, Cox, Cunningham, Chandler, Detroit Electric, Apperson, R. and V. Knight, Dorris, Mercer, Locomobile, Crow-Elkhart and Auburn.

"From the following replies were received that just as soon as an announcement was practicable it would be made: Sayers, Roamer and Stutz."

TO MERGE FORD OHIO PLANTS

COLUMBUS, June 3—Information made public recently indicates that the Columbus assembling plant of the Ford Motor Co. will probably be discontinued when the new large assembling plant, planned at Hamilton, Ohio, is completed. The Hamilton plant will be started soon and will cost $400,000. It will have a capacity of 30,000 cars yearly. In the event that no changes are made in the plans both the Columbus and Cincinnati plants will be merged into the one at Hamilton.

W. C. SERAN UNDER CHARGES

BLOOMINGTON, ILL., June 6—W. C. Seran, president of the defunct Federal Auto Supply Co., has been charged with violation of the Illinois Securities Act in an information filed in court upon complaint of W. M. Conger, who invested $1000 in the firm. It is charged that the stock was not marked "speculative" and that other requirements of the act were not complied with by Seran. The company went into bankruptcy when a court judgment for $90,000 was secured.

MORE COMPANIES CUT PRICES

Drastic Price Cut Is Made by Dodge

$300 Slash on Open Models and More on Closed—Ads Withhold Figures

DETROIT, June 8—Dealers were notified to-day by Dodge Bros. factory officials that sharp reductions in prices would become effective immediately. It had been expected that some action on prices would be taken soon, but the cuts were deeper than dealers anticipated. Following are the old and new prices:

	Old Price	New Price
Touring car	$1285	$985
Roadster	1235	935
Coupe	1900	1585
Sedan	2150	1785
Screen side express wagon	1270	1085
Panel delivery wagon	1350	1135

The price of the touring car at the beginning of 1917 was $785, the coupe $950 and the sedan $1,185.

The decision to cut prices was not unanimously approved within the Dodge organization, and the widows of John and Horace Dodge are said to have cast the deciding vote in favor of the reduction. It is understood that price readjustment had been virtually agreed upon late in April, but the announcement was deferred more than a month.

Liberal space was used to-day by Dodge dealers throughout the country in advertising the price reductions, but in one respect the advertisements differed from those of other companies. No figures were given and the only way in which prospective purchasers could get the new prices was to communicate with the dealers. The underlying theory back of this plan appeared to be it would result in bringing more prospects into the salesroom and thereby increase sales.

DIXIE FLYER DOWN $150-$275

LOUISVILLE, KY., June 6—The Kentucky Wagon Mfg. Co., maker of the Dixie Flyer, announced price reductions ranging from $150 to $275 on its models. The touring car and roadster are reduced from $1595 to $1445, the coupé from $2570 to $2295 and the sedan from $2570 to $2345.

BREWSTER MAKES BIG CUT

NEW YORK, June 9—Brewster & Co., Long Island City, has reduced prices on the roadster and 5-passenger models to $7,000. The cars formerly were listed at $7,900 and $9,000 respectively. No change is made in the inclosed car prices.

Norwalk Motor Car Co., Inc., of Martinsburg, W. Va., makers of the Norwalk car, has reduced the price on its 5-passenger model from $1,285 to $1,135.

Raleigh Motors Corp., Bridgeton, N. J., has reduced prices on its 3 and 5-passenger models from $2,750 to $2,250; on the coupé from $3,600 to $3,100, and on the sedan from $3,700 to $3,200.

Birch Motor Cars, Chicago, has reduced prices on its roadster and 5-passenger models from $1,689 to $1,595.

British Factories Cut Prices to New Levels

LONDON, May 24 (by Mail)—Automobile trade in England is at a standstill. This applies to trucks as well as passenger cars, although it was expected that the miners' strike would give some impetus to sales of commercial vehicles.

Failure of this hope to materialize probably is due to the general slump in all lines of industry.

Prices on practically all British cars except Rolls-Royce and Napier have been substantially reduced and there is sharp competition for whatever business there is. With an improvement in exchange rates, American exporters will have an excellent opportunity to get a better grip than ever before on the British market.

Kissel Reduces $500 on Standard Models

HARTFORD, WIS., June 8—Price reductions of $500 have been made by the Kissel Motor Car Co. on the coupé and sedan of the Standard model line, bringing the new price to $3,775. The 7-passenger touring and the roadster remains at $2,775 and $2,975 respectively. No price change is made on the De Luxe line with regular equipment. The one-ton truck chassis is reduced from $2,175 to $1,585.

AMERICAN CUTS $200 TO $345

NEW YORK, June 9—Price reductions ranging from $200 to $345 have been made by the American Motors Corp., Plainfield, N. J., manufacturers of the American Balanced Six. The new prices are: Sedan $3150, 4-pass. sport $2350, 7-pass. touring $2275, 5-pass. touring $2195, roadster $2195. Former prices on each of these models were $3495, $2595, $2475, $2395, $2395. The new prices are guaranteed until Jan. 1, 1922.

COLUMBIA MAKES $350 CUT

DETROIT, June 9—Columbia Motor Car Co. has announced a price reduction on all models averaging $350. The new prices are to take effect at once.

CANADIAN FORD DIVIDEND

WINDSOR, ONT., June 8—The Ford Motor Co. of Canada has declared its regular annual dividend of 15 per cent.

Excise Tax to Stay, Washington Believes

Protests Considered Vain Unless Drastic Changes Are Made in Government Plans

WASHINGTON, June 3—Though the House Committee on Ways and Means has not taken up the question of internal tax revision, it is believed that the automobile industry will be accorded little relief from the present tax burden. The Senate Committee on Finance has closed hearings on the tax revision but has not indicated its opinion on the various proposals submitted by the automotive and other industries. The opinion prevails that the excess-profits tax will be abolished and possibly a 15 per cent tax on corporations substituted, the excise tax retained but not increased, for a year or two at least, the surtaxes lowered and certain minor taxes abolished because of the expense attached to their collection.

The views of the National Automobile Chamber of Commerce, the National Automobile Dealers' Association, Motor and Accessory Manufacturers' Association, and other automobile organizations which were presented to the Senate, will be submitted to the House Committee on Ways and Means at an early date as part of the Senate testimony. Nobody is willing to believe that the House committee will adopt proposals of the former Secretary of the Treasury that a horse-power and gasoline tax should be levied as additional source of revenue.

Unless drastic changes are made in the conduct of the Government, the excise tax will be retained, despite all protest, because it has, in the opinion of the Treasury, proven a reliable and satisfactory means of income. Frankly, Congress is particularly desirous of enacting revenue legislation which has no political boomerang.

The Senate has practically closed all hearings on internal revenue revision. There have been strong indications of their opposition to the sales tax plan and, in fact, it is generally believed that there is no hope for the sales tax at this session.

Tariff to Arouse Haggling

The introduction of the permanent tariff in the House probably will be a signal for almost interminable controversy. It could not be otherwise. It is the duty of the House Committee on Ways and Means to originate internal revenue measures, but it is doubtful if the committee can give its full time and consideration to these proposals for several weeks. If the permanent tariff is presented by June 15, practically every minute of the committee's time will be taken with defense and explanation of the schedules. The haggling over rates will not permit the tariff framers to devote time to tax hearings.

The Senate cannot take any action on the tariff until it passes the House.

Hoover to Arrange Statistics Service

Exchange of Information for Mutual Benefit Outlined at Committee Meeting

WASHINGTON, June 3—A tentative arrangement was made here to-day for the compilation of more comprehensive automotive production figures to be published for the information of other lines of business. Steps to this end were taken at a meeting of Secretary of Commerce Hoover with a committee representing the industry.

Secretary Hoover discussed quite frankly with the committee his object in asking that representative production figures be supplied to him monthly. He said that other industries had asked for these figures, representing to him that their business depended upon some knowledge of the number of vehicles produced. He added that the automotive industry had become such a power in the business world that other business needed to know something of its activities, just as the iron and steel and railroad figures were an index to activity.

J. Walter Drake, spokesman for the committee, discussed figures that would be helpful to the industry. He said that better crop figures were needed and that the industry could use to advantage more specific figures on steel, income taxes, railroad freight ton miles, railroad passenger miles, totals of business done by the textile, shoe and meat industries. He said that most of these figures were available too late to be of best use and that their sources were widely scattered.

In the conclusion, Drake proposed that the industry submit a written memorandum of the figures that could be supplied through the National Automobile Chamber of Commerce. He said he did not doubt but that monthly figures on factory sales (practically equal to production) could be supplied, separated into certain price classes. Secretary Hoover was quite positive that figures must be so separated to be of best use.

Seeks General Outline

Drake demurred at supplying figures indicating the activity as compared with capacity. He said that capacity was a doubtful proposition. Secretary Hoover made it very plain that he did not want figures that would in any way embarrass the industry, nor was he interested in the individual factory activity. He wanted only a picture of the industry as a whole. Secretary Hoover also said that he would work out a price classification of exports by prices as soon as the clerical labor could be arranged.

Drake will also submit a memorandum of what figures the industry wants. Secretary Hoover said these would be available in the near future, if they were as already outlined.

The Secretary asked that the industry recommend some person to be a representative of the industry on his staff. He wanted a broad gauge salesman with a statistical turn of mind. This person is to plan the information gathering campaign, both in this country and abroad and for a period will be on the Department of Commerce staff. Also he wanted suggestions for a man to serve as a connecting link between the Bureau of Standards and the industry. This man, he said, should be an engineer with production ideas.

Those present at the conference were: J. Walter Drake (Hupp), Percy Owen (Liberty), Alfred H. Swayne (G. M. C.), A. T. Waterfall (Dodge), E. A. Williams (Garford), Gaston Plaintiff (Ford), J. E. Kepperley (Overland), H. S. Vance (Studebaker), R. A. Hauer (International), M. L. Hemmingway (M. A. M. A.), Pyke Johnson and John C. Long (N. A. C. C.), T. F. Cullen (Chilton Pub. Co.), Clyde Jennings (Class Journal Co.)

Motor and Accessory Business for Four Months Shows Big Sales Gain and Drop in Past Due Bills

NEW YORK, June 8—Information gathered by the credit department of the Motor & Accessory Manufacturers Association regarding actual sales and credit conditions for the first four months of the year shows an amazing increase in business from January through April and a surprising decline in past due accounts. The figures, compiled from reports made by members of the association, follow:

Month	Total Purchases	Per cent Change	Total Past Due	Per cent Change	Total Notes Outst'g	Per cent Change
January ..	$6,264,587		$8,099,727		$4,359,871	
February .	10,408,962	66.15 Inc.	6,717,165	17.07 Dec.	6,063,118	39.08 Inc.
March	20,120,386	93.30 Inc.	5.603,992	16.57 Dec.	5,069,877	16.38 Dec.
April	26,746,580	32.93 Inc.	5,352,271	4.49 Dec.	5,371,086	5.94 Inc.

Main Will Supervise Purchases in G. M. C.

DETROIT, June 8—J. H. Main, for 10 years purchasing agent for the Cadillac Motor Car Co., has been appointed director of the purchasing section of the Advisory Board of the General Motors Corp., with offices here. He will be succeeded by D. F. Holgrave, who has been an employee of Cadillac for 13 years and for the last three years assistant to Main.

Main is considered one of the best informed men in the purchasing end of the industry and is an authority on iron and steel.

Sloan and Raskob Leave to Study Export Field

NEW YORK, June 9—Alfred P. Sloan, Jr., vice-president of the General Motors Corp., in charge of operations, and John J. Raskob, chairman of the finance committee of the corporation, will sail on the Aquitania, June 14, for a month in England and the Continent.

While their trip is primarily in the nature of a vacation, they will take advantage of the opportunity to determine matters of general policy pertaining to the General Motors Export Co. and study business conditions with special reference to the export situation for American cars.

South Bend Honors Studebaker Leader

Charles M. Schwab Principal Speaker at Testimonial to A. R. Erskine

SOUTH BEND, June 6—Citizens of South Bend gave a testimonial dinner to A. R. Erskine, president of the Studebaker Corp., tonight at which a magnificent silver service was presented to him. Charles M. Schwab, president of the Bethlehem Steel Corp., was principal speaker. He declared the present industrial depression was the best thing that could happen to the country at this time, and that through this depression business would get back to a real basis of economy.

"We have not been economical but we are going to be soon," he said.

Schwab had just returned from a study of conditions in Europe and regarding this said that it was his opinion that Germany would reap the real benefits of the war unless the United States got back to a solid foundation. He said the United States could compete with any nation of the world, but declared capital and labor must work hand in hand to insure a prosperous future.

In speaking of the Studebaker plant after an inspection trip he said he could find no place where he could suggest improvement. He believed this to be the greatest age of all time, that all should be of good cheer and optimistic. Among other speakers were Governor McCray of Indiana, Waddell Catchings, New York banker, and Walter C. Alien, president of the Yale & Towne Lock Co.

International Declares Regular July Dividend

NEW YORK, June 8—Directors of the International Motor Truck Co. at a meeting yesterday declared the regular quarterly dividend of $1.75 a share on the first and second preferred. The dividend is payable July 1 to stockholders of record June 21. International Motors has done a substantial business during the entire period of depression and its cash position is very strong.

Six Moore Officials Convicted of Fraud

Jury Returns Verdict After Four Weeks' Trial—Seek Disposition of Funds

ST. LOUIS, June 6—Five former officers and a former stock salesman of the Moore Motor Vehicle Co., Danville, Ill., have been found guilty of using the mails to defraud by a jury in the East St. Louis Federal Court. The charge resulted from sales of stock in the Moore company. The convicted men are: George L. Moore, Los Angeles; Edward K. Gallagher, Minneapolis; Albert C. Leonard, Denver; John K. Bichl, Chicago; James H. Vickers, Harvard, Ill., and J. W. Patt, Salt Lake City. The latter was the stock salesman. A motion for a new trial was made.

The story of the Moore company, from its inception in a village in Minnesota to a $5,000,000 corporation, was revealed during the progress of the trial. A salesman of the Ford car, his home in the wilds of Minnesota, George W. Moore came into possession of $4,700 worth of used cars taken by a country bank as security for a bad debt. It is asserted by the Federal authorities that Moore gave his unsecured note to the bank for the possession of the cars, and upon this basis organized the corporation of five millions and sold $1,600,000 worth of stock, built many motor cars and went broke, all within four years. The Federal authorities are endeavoring to learn where the money went.

Moore and his associates are charged by the Government with misrepresentation in their efforts to dispose of stock and that the salesmen they employed made impossible allegations. It is further charged that Moore, after he had decided to launch his company, appointed A. C. Leonard, a clerk, and Edward K. Gallagher, a chauffeur, as officers of his company.

From $50,000 to $5,000,000

They first incorporated for $50,000 in Minnesota and later for $5,000,000 in North Dakota, sold the first company to the second company and then launched a campaign of stock selling which assigned 500,000 shares at $10 each in order to capitalize the company to a paid-up basis, and known as "common stock"; $2,000,000 of preferred stock, and $500,000 as "voting" stock, apportioned among the officers and their friends. George Wilson was appointed stock salesman and received 35 per cent of all sold. He died recently. It was alleged at the hearing that Wilson sold the stock at any price he could secure for it, ranging from $3 to $10 per share.

It was asserted that from the time the company was first formed, little effort was made to manufacture cars, the principal business being, apparently, to sell stock. The "voting" stock was restricted to certain persons, as it had ten times the voting power of the common and preferred stock issued to the public in general. The money rolled in so rapidly that Moore became tired of receiving it and delegated this task to a stenographer. He is quoted as saying:

"It was the first time that I knew that a piece of paper could be sold for $10."

Not long after the company began to turn out cars, the operations appeared to show a loss and the stockholders forced a receivership in the hope of recovering their money. Clarence C. Smith, former auditor, testified that the company experienced a loss of $150 upon each car produced. In all 612 cars were marketed.

Employed 30 Stenographers

At one time thirty stenographers were employed whose duties were to send out literature during the stock selling campaign. Louis Platt, former mayor of Danville, testified that the Association of Commerce of that city subscribed to $20,000 worth of stock of the Moore company as an inducement for them to locate. A. Baenger, a consulting engineer of Minneapolis, was sent to Danville to make an appraisal of the Moore plant and fixed the value at $200,000 in 1918. He declined to make any estimate upon the value of the goodwill, due to lack of reliable information.

The plant of the Moore company at Danville is now owned by the American Building Association of Danville, purchase being made for $54,000 when the receiver placed the property upon the market. This money goes to the stockholders after receiver and court costs and various other obligations are satisfied. The indications are that the stockholders will receive but little unless the Federal authorities have better success than the receiver in locating the millions said to have been secured from the sale of stock.

File Petition Against St. Louis Supply Company

ST. LOUIS, June 6—An involuntary petition in bankruptcy has been filed in United States District Court against the American Automobile & Supply Co., this city, by three alleged creditors, whose claims aggregate $1,172.35. It is asserted that during the past three months the defendant has committed acts of bankruptcy by making preferred payments to creditors.

In connection with the action, Luke A. Pryor, now a farmer at West Point, Ark., has been arrested under an indictment charging him with obtaining $55,000 in property and securities under false pretences in selling the automobile company to E. Mason Roberts.

TIRE RECEIVER APPOINTED

NEW HAVEN, CONN., June 6—The City National Bank of Bridgeport has been appointed temporary receiver of the Kelly Tire & Rubber Co. upon application of the Martin Tire & Rubber Co. The receiver is authorized to carry on in such manner as he sees fit and has authority to borrow $10,000.

Goodyear Abolishes Board of Control

Duties of Members Taken Over by New Comptroller—S. A. Falor Resigns

AKRON, June 7—Under the Goodyear Tire & Rubber Co. refinancing and reorganization, the new financial management has abolished the board of control, transferring its duties to the supervision of George E. Einbecker of Milwaukee, who assumes charge of the newly created office of comptroller. This change has resulted in the resignation of Shelby A. Falor, for four years a member of the board of control and formerly in charge of motorcycle and bicycle tire sales. Falor leaves Goodyear to become president of the Universal Drug Co. of Akron, operating a chain of drug stores.

Other members of the board of control who remain with the company but who are assigned other duties are W. D. Shiltz, now assistant secretary of the company, H. B. Hamlen, and W. D. Oburn.

Reports Assets, $198,000,000

AKRON, June 3—"With net tangible assets of $135,000,000, with net quick assets of $63,000,000 and with a total provision of nearly $43,000,000 for adjustment of inventories and for raw materials not yet delivered, the Goodyear Tire & Rubber Co. will be in an exceptionally strong position and looks forward with full confidence to a future of steadily expanding and profitable business, says a statement issued Tuesday by the new management of Goodyear, in connection with the issuance of a new balance sheet as of Feb. 28, 1921.

The company's estimate of net income for interest and taxes for the 12 months to Feb. 28, 1922, is $10,600,000. Net income for the past five fiscal years, after deduction of the inventory adjustment, averaged $12,575,269, the statement reads, or approximately two and three-quarter times the combined annual interest.

The balance sheet shows provision made amounting to $24,000,000 including an additional $8,850,000 for loss on raw materials under contract but not yet received.

Total assets in the new balance sheet are listed at $177,228,515.88. These include property and equipment at Akron of $58,396,088 less depreciation of $11,329,918; the Sumatra rubber plantation at $5,489,828 and branch equipment and automobiles at $1,696,051. In the Oct. 31 balance sheet the Akron plant was listed at $57,913,143, the Sumatra plantation at $5,003,541 and branch equipment and automobiles at $2,393,891. Current assets under the new balance sheet total $42,201,915, including $1,298,838 for work in process and $19,622,250 in finished product. The company has $11,176,095 cash on hand and $19,332,995 in notes and trade acceptance and other assets of $12,500,000.

Colombian Business Due for Quick Boom

Temporary Slump Occasioned by Financial Pinch Passes—Open Up Oil Resources

NEW YORK, June 3—The expectation that business with Colombia will shortly return to normal was expressed in statements just received here from the American Chamber of Commerce of Colombia, Barranquilla, Colombia, the chief port of that rich country. Writing under date of May 18, R. L. Parrish, the acting secretary, declared:

"The business situation in Colombia has at no time been as acute as in other countries. Colombia has no national or municipal debts to speak of. The balance of trade for many years until the last two had been continually in Colombia's favor, which resulted in a substantial accumulation of wealth in individual hands. The sudden slump in prices in 1920 caught a good many importers who had been overbuying and they individually lost some money. The foreign business here was mostly through the American banks. When they shut down suddenly under orders from the United States, the situation was serious and business has not yet recovered its normal tone and volume.

"However, it seems that the situation is growing more tolerable and, in my opinion, Colombia is due for a boom. The foreign trade of Colombia in 1920 approximated $140,000,000, of which considerably more than $100,000,000 was with the United States. The greatest present activity is in the development of the oil resources, mostly by American companies, who are spending large amounts in that line."

Exports of passenger cars to Colombia in 1920 totalled 962, valued at $1,247,976, a striking increase from the 1919 total of 253 with a value of $298,383. Truck exports jumped from 38 in 1919 to 275 last year and parts purchases tripled, the 1920 total being $216,772.

Colombia Starts Roads As Lower Prices Arrive

WASHINGTON, June 3—Road and pavement building has been resumed in Colombia along with a general resumption of construction work on buildings and other public projects. This, according to reports received by the Bureau of Foreign and Domestic Commerce, is due to lowered cost of materials and labor and has resulted in many projects being started which necessarily were halted while prices were high.

Road interest has manifested itself in various parts of the country. In addition to improvements made on roads to outlying towns in the vicinity of Barranquilla, work is continuing on the road being constructed between Barranquilla and Cartagena. This 99 kilometer stretch has been under construction about six years and at present the part from Barranquilla to Sabanalarga and Manati is now in use. The Department of Cauca is also undertaking road construction.

The problem of street paving in Barranquilla is an important one and, according to estimates, will involve an expenditure of about $3,000,000. Plans for the financing of this project were discussed at a municipal meeting attended by the principal merchants.

Americans Monopolize Maltese Car Market

WASHINGTON, June 3 — Consul Carl R. Loop, at Valetta, Malta, has reported to the Bureau of Foreign and Domestic Commerce that according to the register of licensed motor vehicles, the most popular makes of foreign automobiles are English and Italian, and of foreign trucks, English. However, the current market is almost entirely monopolized by United States passenger cars, and no new trucks, other than those of United States make, are being offered for sale at the time the report was made.

During the war, the military forces imported lorries and ambulances in considerable numbers and such vehicles are now being sold to private concerns. The list prices at which passenger cars are being sold in Malta vary from £220 to £2600, or, at the then current rate of exchange, $858 to $10,140, the most popular makes selling at £365—$1424—and £410—$1599. The list price of an Italian machine is £450—$1755—and £1080—$4212, respectively. Discounts to distributors are usually 20 and 2½ per cent, but in one case of United States cars and trucks the terms are cash against documents. An Italian company allows its distributors 60 days, and similar terms are the rule with English and French cars.

The four-cylinder car is more popular than the six, for the reason that it is considered to be more economical. The one or two-ton truck is the most popular, as distances are short, the streets and roads narrow, and winding, and business is not sufficiently heavy or congested to require large trucks. According to the official register, 237 passenger cars were licensed in 1920 and 93 trucks.

CRANKCASE DILUTION GAGE

TRENTON, N. J., June 3—E. S. Lea has developed an instrument which when applied to the crankcase of an internal combustion engine indicates to the operator when his crankcase oil has become so much diluted with gasoline or kerosene that it should be replaced. It consists of a float chamber with overflow through which the crankcase oil is circulated by the pump of the lubricating system. When the oil gets too thin a red signal attached to the float shows behind a window. The signal is also out of sight when the oil is not circulating, and the instrument therefore also serves as a circulation indicator. For automobile use the instrument can be applied to the instrument board.

Exports and Imports Fall Off in England

Percentage of Reduction Heaviest on Import Trade—Labor Dispute Harmful

LONDON, May 13 (By Mail)—Official statistics for April's British import and export trade at large reflect very clearly the setback caused by labor disputes culminating in the hold up of manufacturing industries and shipping to an increased extent.

Britain imported in April 399 cars against 1914 in April, 1920, 209 trucks against 1139 in April, 1920, and 274 chassis against 1295 in April, 1920. The value of the chassis parts imported was roughly $1,017,200 against $3,606,700 in April, 1920.

Motorcycles imported were 71 against 475 in April, 1920, but curiously there was a bigger import value of parts, the respective values being for April, 1921, $63,020, and April, 1920, $61,665. The import value of tires fell from $2,506,970 April, 1920, to $817,810 April, 1921, which is a fair criterion of the state of the industry.

The export of British cars was 179 in April, 1921, as against 202 in April, 1920, and their destinations were respectively—British India 28, New Zealand 12, other countries (not specified) 139. The month's export of chassis was 102 against 155 in April, 1920, as follows: South Africa, 5, and other countries (not specified), 97. The month's export of trucks was 88, as against 78 in April, 1920, as follows: British India 33, New Zealand 4, other countries (not specified) 51.

The export value of British tires fell from $1,260,980 April, 1920, to $929,985 April, 1921. These rates are taken at the nominal rate of exchange, viz., $5 to a British £1.

Fiat Polish Factory Starts Work at Warsaw

NEW YORK, June 6—Poland's first motor car factory has been opened at Warsaw, under the title of Spolka Akcyjna Samochodow Polski Fiat, with a capital of five million Polish marks. The new concern, which is most generally described under the abbreviated title of the Polish Fiat, is an offshoot of the big Italian Fiat Co. of Turin, one-half of its capital having been subscribed by Polish financiers, and the rest being of Italian origin.

The Polski Fiat has a modern factory and garages at Warsaw, with a branch at Lodz and representatives at Lublin, Posnan and Leopol. The works are now in full production under the technical direction of the Italian Fiat Co., for the Polski Fiat car is still dependent on the home factory for many of its components. Business conditions are reported to be very promising, the firm having important orders in hand.

Berliet Deficiency 3,000,000 Francs

Stock in Trade Shown as 65,-444,021 Francs—To Operate Under Receiver

PARIS, May 28 (By Mail)—The Berliet Automobile Co., having been allowed to take advantage of the French law providing for a transactional arrangement with creditors, under which the payment of debts will be spread over a number of years, a statement has been published covering the financial situation of this concern.

Land, buildings and material are valued at 64,190,117 francs; deposits in the bank are 733,375 francs; government bonds represent 1,039,580 francs; outstanding accounts 17,499,710 francs, and general stock in trade 65,444,021, making a credit total of roughly 149 million francs.

The debit account shows 50 million francs in shares, 25 millions in bonds; 4 millions in various provisions, and 73,368,789 owing to various creditors, making a total of just over 152 million francs. The most important trade creditors are Dinin Storage Battery Co., 407,296 francs; Paul Girod Steel Works, 1,446,050 francs; Michelin Tire Co., 1,310,754 francs; Bergougnan Tire Co., 2,254,812 francs; Nilmelior Magneto Co., 680,075 francs.

The Berliet company is continuing in operation under the control of the government receiver appointed to protect the interests of creditors. A popular 16 hp. automobile on American lines is being produced; trucks are also being manufactured, but the present demand is low.

Poor Crop Prices Hurt Porto Rican Market

SAN JUAN, P. R., May 28 (By Mail)—There are now in Porto Rico over 7000 automobiles. Ford leads with a percentage of 33, Buick second with 17 per cent, and then follow Dodge, Hudson, Chandler, Studebaker, etc.

The roads throughout the Island, owing to the heavy rains, are in very poor shape, this condition being heightened by the operation of truck trains, while the railroad strike is on. For the past week all freight has been carried by truck.

Dealers report business dull, owing to the price of sugar and coffee in the main. Tobacco is hardly worth the marketing, while for a whole year the American Tobacco Co. has had a strike on its hands.

There are at present over 50 passenger buses or as they are known here, "Guaguas," in operation between San Juan and Santurco. A new line of passenger buses called the "Blue Line" has been established between San Juan and Ponco. They are 24 passenger White buses, make the run in about six hours and are meeting with great success.

The firm of Cerecedo & Co. of San Juan has sold its business to F. U. Wells & Co., Inc., including Exide, for which it was distributor. By this purchase and including the large stock of batteries already carried by F. U. Wells & Co., it places them greatly in the forefront in the storage battery field in Porto Rico. They also ship to Santo Domingo, St. Thomas, and other islands.

The P. R. R. R. Co. has adopted wheels for Ford cars, by which they can use the railroad tracks, and are using them as work and inspection cars.

Territories Withdrawn by Ford in Argentina

NEW YORK, June 3—Confirmation that changes are being made in the operation of the foreign business of the Ford Motor Co. has followed the announcement from Buenos Aires of the resignation of E. H. Hampton, manager of the Ford Argentina plant. Advices from Detroit quote W. A. Ryan, the Ford general sales manager, as admitting that the changes are being made in all territories, but he would give no details. Ryan confirmed the resignation of Hampton, whose successor has not been named.

The resignation of Hampton was one of the results, according to reports, of the withdrawal of the exclusive territory to the 325 Ford dealers in Argentina.

R. I. Roberge, manager of Ford foreign sales, has removed his office from New York to Detroit. It is stated that he will handle the major problems of Ford sales from there.

Engine Production Grows Six Times in Five Years

WASHINGTON, June 4—Statistics of engines produced in 1919 as compiled by the Bureau of Census, show that gasoline automobile engines produced in that year were valued at $58,548,000, as compared with $10,122,000 in 1914. Other internal combustion engines, including aviation, were valued at $13,-185,000 in 1919; marine, $10,153,000; gasoline stationary, $37,243,000; gas stationary, $10,571,000; portable gasoline engines, $1,127,000, and all other gasoline engines, $1,882,000. Traction engines for farm, military, road and other purposes produced in 1919 were valued at $124,546,000 and in 1914 $4,209,000. Automobile engines listed as steam engines and others were valued at $3,004,-000 in 1919. The census reported 199 establishments making internal combustion engines and 85 traction engines.

DAVIS SALES LEAD 1920

RICHMOND, IND., June 3—The George M. Davis Motor Car Co. produced and sold more cars in April, 1921, than in April, 1920, according to Walter C. Davis, secretary and sales manager. Production this year exceeds that for the same month last year by 9 per cent, and the factory is working at its full production schedule. The new cars have met with a gratifying reception.

METAL MARKETS

THERE is no longer any doubt that once the present period of intensive dullness in the steel market shows signs of waning radical reductions in the price schedule of the leading market interest may be looked for. Developments so far have been absolutely in line with those which preceded the previous announcement of cuts in the United States Steel Corp's prices. Then as now it was the American Steel & Wire Co. which led the other subsidiaries of the corporation in the downward revision of prices. That a general reduction in the prices of steel products will be proclaimed by the chief producer at the first sign of a reawakening of representative demand is the belief of conservative market observers. Those who are more radical profess to see in the American Steel & Wire Co.'s announcement indications of a price war or at least of carte blanche given by the corporation to its sundry subsidiaries to meet all price cuts by independent producers. Some characterize the present condition as a "wide-open market." There is, however, very little likelihood of any alteration in the orthodox manner in which steel prices have now been made for many years. Here and there a voice in the "independents'" camp will be heard to the effect that they made a mistake when they raised their prices to bring them up to the levels of the corporation following the latter's last price revision. But in spite of the vicissitudes through which the steel industry is passing sentiment is overwhelmingly in favor of a continuance of the present market generalship. For the present no fault will be found with any producer if he can garner in business that will keep part of his plant running, even though he has to cut way under the corporation's levels. If perchance much business of this character should materialize it will make readjustment or more permanent levels much easier. The automotive industry continues to figure prominently in shipments, but very little in the way of new orders from that source is reported. Reports current in the Youngstown district that the leading maker of low-priced passenger cars contemplated a shutdown of his plants on July 1 were followed on the heel by others that said passenger car builder would enter the market for another tonnage of sheets this week.

Pig Iron.—Manufacturers of automotive engine castings in the Middle West who have been buying on a modest scale during May are curtailing their shipping orders. Although the nominal quotation for No. 2 foundry remains at $23 valley, and for malleable on a like basis, concessions are not difficult to obtain.

Steel.—The sheet tonnage placed by the leading manufacturer of low-priced passenger cars in the last few weeks with mills in Ohio (outside of the valley) and in Pennsylvania, is said to amount to 10,000 tons. A valley producer took 500 tons on a release at 4 cents with extras, the original price having been 8 cents. Canton, Mansfield and Connellsville mills are working on sheets for this consumer. In Youngstown predictions are freely made that sheets will sell on a basis of 3 cents for the black and at proportionate prices for blue annealed and galvanized before the summer is over. Rumors that German sheet bars have been bought at $34 laid down in New York are generally scoffed at in the trade. Laid down at sheet mills the price of these sheet bars would be such that it would be unattractive. Cold-drawn bars are in light demand with a small tonnage on its way to the Cadillac Motor Co. from Pittsburgh district mills.

FINANCIAL NOTES

Maxwell Motor Corp. one, two and three year notes and stock certificates are ready for delivery at the office of the Central Union Trust Co., New York. Holders of certificates of deposit for notes and claims already approved will be entitled to receive cash and notes in the amounts provided in the reorganization plan. Holders of subscription warrants fully paid will be entitled to receive the shares of stock called for by the warrants. Holders of certificates of deposit for stock will get the new stock in accordance with the terms of the plan.

Chandler Motor Car Co. directors have reduced quarterly dividend payments from $2.50 to $1.50 and have declared the usual quarterly payment at the new rate. The $2.50 rate had been paid since October, 1919, when the old stock of $100 par was exchanged for the current shares of no par. This action by Chandler had been expected in the financial community and had been discounted by the recent break of 20 points in the stock.

McCord Mfg. Co. will be back on its feet by August, declares a banker interested in the readjustment of the company. The Detroit plant, which makes radiators, did enough business to offset the slack in other departments without any new money. The company has nearly $500,000 cash on hand, liquidation of inventory is proceeding satisfactorily, payables are being rapidly reduced and quick assets increasing.

United Auto Stores, Inc., directors have authorized a stock increase from $1,000,000 preferred and 40,000 no-par common shares to $5,000,000 8 per cent cumulative preferred (par $100), and 200,000 no-par common shares. Preferred and common stockholders of record June 10 will receive a dividend of 20 per cent in common stock.

International Harvester Co. directors have voted to reduce the dividend rate on the common stock from 7 to 5 per cent and voted a stock dividend of 2 per cent payable July 25. The quarterly cash dividend is payable July 15. Stock outstanding totals $92,000,000. No further reduction in the dividend rate is probable, the directors said.

Burdick Tire & Rubber Co., Noblesville, Ind., has mortgaged its factory for $250,000 to the First Dearborn Savings & Trust Co., Chicago, as trustee, and James S. McClellan, Chicago, as co-trustee. The mortgage runs 10 years and draws 8 per cent interest.

Lee Rubber & Tire Corp. reports sales for the first four months of 1921 exceeded $2,137,000, or 75 per cent of the corresponding period in 1920. April, 1921, sales established a new record at 34,333 casings. Output was reported exceeding 1700 casings daily.

Electric Storage Battery Co. has declared the regular quarterly dividend of $3 on the common stock and the regular quarterly dividend of $3 on the preferred stock, both payable July 1.

Advance Rumely Co. has declared a regular quarterly dividend of 1½ per cent on the preferred stock, payable July 1.

INDUSTRIAL NOTES

Paul Rubber Co., Salisbury, N. C., is erecting a plant for the manufacture of tires. The company expects to be manufacturing tires in 90 days' time. The company is now operating a factory in Chicago, with C. T. Brown as sales manager. When the Salisbury plant is completed it will be made the main factory and the entire organization will move to Salisbury.

Atwater Mfg. Co., Southington, Conn., employing about 250 in the manufacture of drop forgings, has closed down for an indefinite period. It has been operating on a two-shift schedule of eight hours each for the past month. The factory had a large rush order for the Ford Motor Co., which it filled this week.

Altenberg Tire Equipment Co., Davenport, Iowa, has been reorganized with V. D. Sears, president and sales manager, and Ralph T. Hayes, production manager for Moline Plow Co., vice-president and general manager.

Goodyear Tire & Rubber Co. announces that the shutdown of the plant from June 25 to July 5 will not be occasioned by business conditions, but will be solely for the purpose of taking the regular annual inventory.

Rainier Motor Corp. has removed its New York headquarters to 235-7 West Fiftieth Street, where it will have an entire building for sales and services.

Arvac Mfg. Co., manufacturer of accessories at Anderson, Ind., will increase its output May 31 and has notified workers formerly laid off to report.

New Departure Mfg. Co. has removed its Chicago sales and engineering offices to the Peoples Gas Building, 122 South Michigan Avenue.

Gray & Davis, though reducing operations to the plane of current business demands, will continue manufacturing on a substantial scale.

Rome Wire Co. has opened New York sales offices at 50 Church Street under the direction of H. A. Hammond, district manager.

Milburn Capital Stock Increased to Million

TOLEDO, June 6—At a meeting of the officers and directors of the Milburn Wagon Co. it was unanimously decided to increase the common stock of the company from $625,000 to $1,000,000 for the purpose of absorbing the accumulated surplus.

The company will put on about 600 men this month in order to bring its production of bodies for the Olds Motor Co. up to schedule. There are now 220 men employed in the production of Milburn electrics. The schedule calls for about four cars a day.

Officers of the company elected for the year are: Horace Suydam, president; Otto Marx, vice-president; Frank D. Suydam, Jr., secretary, and F. H. Dodge, treasurer.

Maibohm Sues Chamber for Breach of Contract

TOLEDO, June 6—The suit of the Maibohm Motors Co. of Sandusky against the Sandusky Chamber of Commerce for $100,000 for alleged breach of contract will be heard before Judge Harvey Platt, of Tiffin, of the Common Pleas Court.

The motor company brought the suit for damages, charging that the Chamber of Commerce refused to fulfill its part of a contract when the company moved its plant to Sandusky from Racine, Wis., two years ago.

It is expected the trial will begin in the next two weeks.

BANK CREDITS

Written exclusively for AUTOMOTIVE INDUSTRIES *by the Guaranty Trust Co., second largest bank in America.*

NEW YORK, June 9—The money market during the past week was characterized by a decided firmness which carried over into the present week. On Thursday call money reached 8 per cent, the highest rate since Feb. 8. The range for the week was 7 per cent to 8 per cent as against 6½ per cent to 7½ per cent in the previous week. Most of the transactions were put through at 7½ per cent. Time money showed tendencies similar to those for call money. Rates for all maturities from 60 days to 6 months were 6¾ per cent to 7 per cent as against 6¾-7 per cent for 60-90 days' and 4 months' paper and 6¼-7 per cent for the longer maturities the week before. Funds were scarce and the supply apparently small, judging by the amount which a 7 per cent bid drew forth. The present firmness is not, it appears, consistent with the usual movement following the meeting of first-of-the-month requirements. There were, however, some Government withdrawals during the week, and a fair amount of new financing.

For the second time in the current year, and for the first time since Feb. 25, 1921, Federal Reserve note circulation of the Reserve System showed an increase. At $2,751,299,000 the Federal Reserve notes in circulation marked an increase for the week of $16,495,000, but are still about $653,632,000 below the peak figures of December 23, 1920. Total gold reserves increased $15,706,000 and total cash reserves $10,598,000.

While the bank statements give evidence of the fundamental improvement which has taken place in the banking situation, there are still signs that the general readjustment has not been completed. Ford has just announced a further cut in the price of his cars, following similar recent announcements by about thirty other automobile manufacturers. Crude oil prices have reached the lowest level in several years, while the steel trade is as yet showing no signs of revival.

It has been estimated that the steel industry is now working at about 25 per cent of capacity as contrasted with about 55 per cent in January and about 80 per cent in the first nine months of 1920. The financial markets have reflected these conditions. In view of further dividend cuts by a number of industrial companies and other unfavorable factors, the stock market declined steadily all week. On Tuesday of the present week many industrial shares reached new levels for the year.

The bond market has been lethargic and gives evidences of needing a respite from the flood of new issues. It was in the foreign exchange market, however, that the most spectacular break came, Sterling declined to $3.76¼ while the French franc broke below 8 cents to 7.88½. Practically all foreign currencies declined on the New York market.

MEN OF THE INDUSTRY

L. D. Maxson has tendered his resignation as purchasing agent of Olds Motor Works at Lansing, Mich., to join Edward Ver Linden, former president of Olds, with the Ver Linden division of the Durant organization. Maxson had been with Olds Motor Works about sixteen years. He will have charge of purchases of all material to be used in the new plant as well as mechanical equipment.

Richard Harfst has been made general manager of the Detroit branch of the Cadillac Motor Car Co., succeeding W. H. Collins, who has joined his father, R. H. Collins, in the latter's new project. For the last year Harfst has been in the office of the president of the General Motors Corp. in New York, from which position he resigned to join Cadillac.

R. E. Wolcott, assistant credit manager, and R. H. Watterman, purchasing agent, of the Miller Rubber Co., have resigned under the company's program of retrenchment of office personnel. The Miller plant is now on a production basis of 3000 tires a day, and expects to continue this program until October.

H. C. Bradfield of Detroit has been appointed director of sales and advertising for the Yellow Cab Mfg. Co., Chicago. Associated with Bradfield as sales manager of the taxicab division is J. B. Dub, who was formerly associated with Bradfield in the former Premier Motor Car Co. of Indianapolis.

A. G. Partridge, who resigned several months ago as vice-president and sales manager of the Firestone Tire & Rubber Co. of Akron, has been appointed sales manager of the Star Rubber Co. He succeeds O. L. Weaver, who it is announced retires on account of ill health.

Sir Henry McGowan, chairman of Nobel's Explosive Co., London, and representative of the British Explosives Trades, Ltd., interests on the General Motors Corp. board, has arrived in New York to attend the stockholders meeting of General Motors the latter part of June.

William C. Williams, production manager of the Chevrolet factory in Fort Worth, has been transferred to the Oakland plant, it was announced here today. Williams came here at the opening of this plant, four years ago. His successor in Fort Worth has not been named.

A. K. McLuney, who left Buick Motor Co. 10 years ago to become Detroit manager of the Studebaker branch and later was a Buick dealer at Utica, N. Y., has returned to Buick, where he is connected with the sales department at the factory.

Hugh W. Stilwell has joined the organization of the Clark-Turner Piston Co., Los Angeles, to take charge of and develop the advertising department. He was formerly connected with the Miner Advertising Agency of Los Angeles.

William J. Wickes, president of the Wickes Boiler Co., Saginaw, Mich., has been made vice-president of the new Ruggles Motor Truck Co., which has taken over the plant of the Saginaw Shipbuilding Co., Saginaw, for its factory.

Fred M. Hoblitt has been appointed general sales manager of the Ajax Rubber Co., to take the place of Fred E. Dayton, who has resigned to become connected with the real estate firm of Cross & Brown in New York.

Paul Andree has been made secretary-treasurer and manager of the Cincinnati office of the R. & V. Engineering Co. He was formerly superintendent in the East Moline factory.

E. P. Mickelberry of Champaign, Ill., has purchased the Bradley Motor Co. business here for $60,000. He will continue the Bradley line agencies with no change in office personnel.

Verne E. Burnett, who has been assistant to Cliff Knoble, advertising manager of the Liberty Motor Car Co., has resigned to join the advertising staff of the Cadillac.

Hays McFarland has been appointed sales manager of the Bassick Mfg. Co., Chicago, manufacturers of lubricating systems.

D. E. Kirk has resigned from the Green, Fulton. Cunningham Advertising Co. to join the Evans-Ayres company.

J. Henry Smith has been appointed vice-president of the Sheet Steel Products Co., Michigan City, Ind.

Goodrich Retrenchment Makes Changes in Staff

AKRON, June 7—Changes in personnel incident to office force readjustments under the B. F. Goodrich Co.'s policy of retrenchment have resulted in the resignations of E. C. Tibbetts as Goodrich advertising manager, James O'Mara, director of publicity; E. P. Rowen, in charge of Diamond tire sales; R. E. Hackenger, assistant advertising manager, and Milton Fassnacht, in charge of tire adjustments.

Tibbetts and Rowen were two of the oldest Goodrich officials, each having been with the company over 15 years. Rowen was formerly with the Diamond Tire Co., joining Goodrich with consolidation of the two companies in 1904. Tibbetts has been with Goodrich for over 25 years.

In addition to office personnel cuts, the Goodrich company has enforced a program of salary readjustments and has limited all vacations this year to one week.

Preston Motors Assigns Cuban Distributorship

BIRMINGHAM, ALA., June 3—J. T. Driver, vice-president and general sales manager of the Preston Motors Corp., announces the initial steps of his concern to go after export business. E. I. Matthews, formerly with the State auditing department of Florida, has been assigned as distributer for that State and Cuba. Matthews expects to leave for Cuba in the near future to perfect his sales and distribution organization for that territory and to launch an extensive advertising campaign.

"Mr. Matthews, being located in Florida, which is just a stone's throw from Cuba, knows Cuba and its marketing conditions, and is going to make us an excellent representative," Driver said. "It is the first step we have taken toward going after foreign business by establishing a direct distributer. However, we are planning an export advertising campaign at the present time and expect to be doing a good export business by next winter. We are going to impress upon the foreign buyer the wonderful location of Birmingham, our direct water route with gulf ports and our excellent shipping facilities."

Court Gives Verdict for Engineering Error

PARIS, May 28 (By Mail—French civil courts have condemned the Automobile Club of France to pay Alexandre Anzani, aviation engine manufacturer, a sum of $2,000 as damages for wrong awards in an aviation engine competition held in 1913. In this competition, which included all the leading French manufacturers of aviation engines for the period, the first prize was given to the Gnome company for its rotary type engine. Considering that there had been a mistake, Anzani had all the figures verified and brought forth definite proof that the engineers of the Automobile Club of France had made errors in their calculations As the club refused to recognize its mistake or to publish any correction in its official bulletin, Anzani brought the matter before the civil courts, with the result stated above.

Leach Biltwell Buys Miller Engine Works

LOS ANGELES, June 3—The Leach Biltwell Motor Co., which has been incorporated with a capital of $5,000,000, has acquired the Miller Engine & Foundry Works of this city. M. A. Leach, president and founder of the motor company, becomes president of the new corporation.

The Miller works were owned by Harry A. Miller, builder of motors for automobile racers, who controlled patents for a new motor which will be constructed especially for the Leach cars. Miller becomes a director and second vice-president of the new company and will superintend the building of the motor. Other officers of the new corporation are John T. Dye, first vice-president; Grey M. Skidmore, treasurer, and James H. Faircloth, secretary.

ALLEGE FALSE STOCK SALES

ROCKFORD, ILL., June 6—Jack Felch of this city has filed information in Belvidere, Wis., against five officers and a salesman of the Prudential Tire & Rubber Co., alleging sales of stock under false pretenses. He claimed that representation was made that the Prudential company, which had leased the Boone Tire & Rubber Co. plant, had taken over its business and on this basis was exchanging $300 stock in the Boone company for $200 stock in the Prudential company and $100 cash. The Boone company still maintains its properties

Calendar

SHOWS

Sept. 5-10—Indianapolis, Automobile and Accessory Show in conjunction with Indiana State Fair, conducted by Indianapolis Automobile Trade Association, John B. Orman, Mgr.

Sept. 28 - Oct. 8 — New York, Electrical Exposition, 71st Regt. Armory, Electric Equipment, Machinery and Vehicles.

Nov. 27-Dec. 3—New York, Automobile Salon, Hotel Commodore.

January — Chicago, Automobile Salon, Hotel Drake.

FOREIGN SHOWS

June, 1921—Reykjavik, Iceland, Agricultural Exhibition—Agricultural Machinery—Icelander Agricultural Society, Reykjavik, Iceland.

September—Buenos Aires, Argentina, Passenger Cars and Equipment. La Pabellon de las Rosas. Automovil Club Argentino.

September—Buenos Aires, Argentina, Cars, Trucks, Tractors, Farm Lighting Plants and Power Farming Machinery. Palermo Park; Sociedad Rural Argentina.

September—Luxemburg, Luxemburg, Agricultural Sample Exhibition.

Oct. 5-16—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

Nov. 4-12 — London, British Motor Show, Society Motor Mfrs. and Traders.

May, 1922—Quito, Ecuador, Agricultural Exposition, celebrating Centenary of Ecuador. Automotive Section.

CONVENTIONS

July 4-9 — Mackinac Island, Mich., Summer Meeting Automotive Equipment Association.

Oct. 12-14, 1921 — Chicago, Twenty-eighth Annual Convention National Implement & Vehicle A'ssn.

Nov. 22—New York, Convention of Factory Service Managers, National Automobile Chamber of Commerce.

RACES

June 18—Uniontown, Pa., Speedway Events.

July 25—Grand Prix, Le Mans.

Labor Day—Uniontown, Pa., Autumn Classic.

Pintle Hook Mounting Standardized by N.A.C.C.

NEW YORK, June 6—The Truck Standards Committee of the National Automobile Chamber of Commerce has adopted the following recommendation: Where a pintle hook is attached to a motor truck or tractor frame, the hook itself shall be of the U. S. Government type. This hook shall be so mounted that the axis of the drawbar head shall be located both vertically and horizontally approximately in the center of the frame of the chassis. A means shall be provided for fastening one end of the safety chain to the rear end of the motor truck chassis frame. The clevis is to be located directly under the axis of the drawbar head or as near to this position as possible.

The Trailer Manufacturers' Association of America has suggested that it is not necessary for the truck manufacturer to place a spring behind the drawbar head or pintle hook on motor trucks. They state that trailers made by reputable trailer manufacturers have a starting and stopping spring in the drawbar or trailer head, which is or should be of proper length and strength so that any additional spring furnished by the truck manufacturer would give too much spring action, causing the trailers to jerk and bump the truck. Nevertheless the N. A. C. C. Truck Standards Committee recommends that wherever possible truck manufacturers equip their drawbar heads with springs for the better protection of the truck frame and driving mechanism.

Dort First and Third in Argentine Road Race

FLINT, MICH., June 6—Establishing a new South American long-distance record for reliable performance as well as fast time, a Dort car won the annual Argentine classic, held this year at Rafaela, northern Argentina. In a field of 16 entries, among which were one Vauxhall, two Fiats and three Dodge cars, the Dort came home the winner.

This annual cross country run covered a distance of 392 kilometers, or 244 miles, over all sorts of roads, which taxed the entries to the utmost. Of the 16 models lined up for the start, only four finished, among which were two Dorts, taking first and third places. The time was 4 hours and 41 minutes, an average of 84 kilometers per hour. This establishes a new South American long-distance speed record and also wins the special prize offered by the Automobile Club of Argentina for regularity in performance.

Progress of Industry to Be Shown in Chicago

CHICAGO, June 3—C. R. Richards, dean and director of the engineering experiment station at the University of Illinois, is making plans for a comprehensive exhibit of the automotive industries during the Pageant of Progress Exposition on the Municipal Pier here, July 30 to August 14. There will be displayed everything that goes to make up an automobile, a motorcycle or an airship with exhibits in this division of the oldest styles of cars and airplanes to the most modern. There will be model factories and actual working exhibits.

Development of the mechanism of automobiles and trucks will be shown inclusive of types of engines, exhibits of early engines, the trend of design in the development of the engine with its cooling and lubricating system, the carbureter, gasoline tank and methods of starting; the transmission system, electric system and the development of tires. This latter exhibit will include a comprehensive display of various types of wheel construction, demountable rims, and strides made in the manufacture of pneumatic and solid tires. An electric dynamometer with some form of modern automobile engine mounted on it and operated will be one of the interesting features of the exhibit.

SUE ON INTERLOCKING STOCK

AKRON, June 7—Seventy-two individual actions have been initiated in the Common Pleas Courts of Summit County at Akron by Elihu Harpham, receiver of the defunct Interlocking Cord Tire Co., against as many stockholders of the company demanding payment of unpaid amounts due on stock subscriptions. The amount involved aggregates $15,432. Recently Harpham filed 36 similar suits.

Speed Limits Lifted on French Highways

PARIS, May 20 (By Mail)—No official speed limit now exists in France, but motorists will be held responsible for the accidents they cause by reason of negligence or incompetence. The wiping out of the speed limit is in accordance with public sentiment, which has long recognized that an arbitrary limit was no protection to users of the road, while often being an arm for the persecution of motorists.

This change has been made in an entirely new set of national laws covering all phases of road travel and abolishing the local and often arbitrary and antiquated regulations in force in various parts of the country. The right hand rule of the road is maintained, despite an agitation in favor of the English or left hand rule. Traffic on national highways has the right of way, and when two roads of equal importance cross drivers must give way to vehicles approaching on their right.

The speed limit is maintained for trucks and passenger carrying vehicles weighing 3 tons. The Government driving license, granted after a practical examination, also has been maintained. Under the new laws all vehicles must carry lights, but dazzling headlights cannot be employed in towns or cities. Animals allowed to wander on the road will do so at their owners' risk.

Quality Tire Creditors File Bankruptcy Appeal

INDIANAPOLIS, June 4—A creditors' petition in bankruptcy has been filed against the Quality Tire & Rubber Co. of Anderson, Ind., in Federal Court yesterday by the Great Falls Mfg. Co., the Marlboro Cotton Mills and the Katzenbach & Bullock Co. In their petition they allege that the tire company is insolvent and sought recently to transfer a portion of its property to certain of its creditors. They also sought to obtain back salary of $215.93 for its president, H. C. Yauky. The Great Falls Mfg. Co. places its account against the tire company at $70,000, the Marlboro Cotton Mills at $112,000 and the Katzenbach & Bullock Co. at $92.

AUTOMOTIVE INDUSTRIES
THE AUTOMOBILE

VOL. XLIV. NEW YORK—THURSDAY, JUNE 16, 1921 NO. 24

Where Are We Getting in Efforts to Solve the Fuel Problem?

A review of research and development work covering results of tests and improvements in design made public during the past year, together with comments on future developments that appear to be promising.

By Herbert Chase

SO much has been said and written regarding the fuel problem and its solution that the situation is more or less confused in the minds of some persons. It therefore seems worth while to attempt to render an accounting of the present situation in order to determine what has been done and if possible what remains to be done in order to reach a solution of the problem.

It is quite generally agreed that the supply of petroleum known to exist in this country, if not in the world, will, if the present rate of consumption continues to increase, at least approach exhaustion within the present generation. Since our present civilization is largely dependent upon this source of fuel supply, it is evident that careful consideration must be given to the conservation and use of petroleum products of all kinds, and in particular those elements available for use in internal combustion engines.

So far as the automotive industry is concerned efforts at the present time naturally and properly center around means for better utilizing fuels in automotive engines. Efforts are also being made to better the character of fuel available, since the efficiency with which fuel can be used, especially in the present prevailing type of engine, is dependent to considerable degree upon the volatility and molecular structure of the fuel.

Looking at the present day car makes it evident that conditions are, in the average case, better than they were a few years ago when the importance of the fuel problem first began to receive wide recognition. Far more remains to be done than has already been accomplished, but it will be evident from examination of the attached chart and the literature on the subject that the work already accomplished is of considerable importance and that the near future holds possibilities of much greater progress.

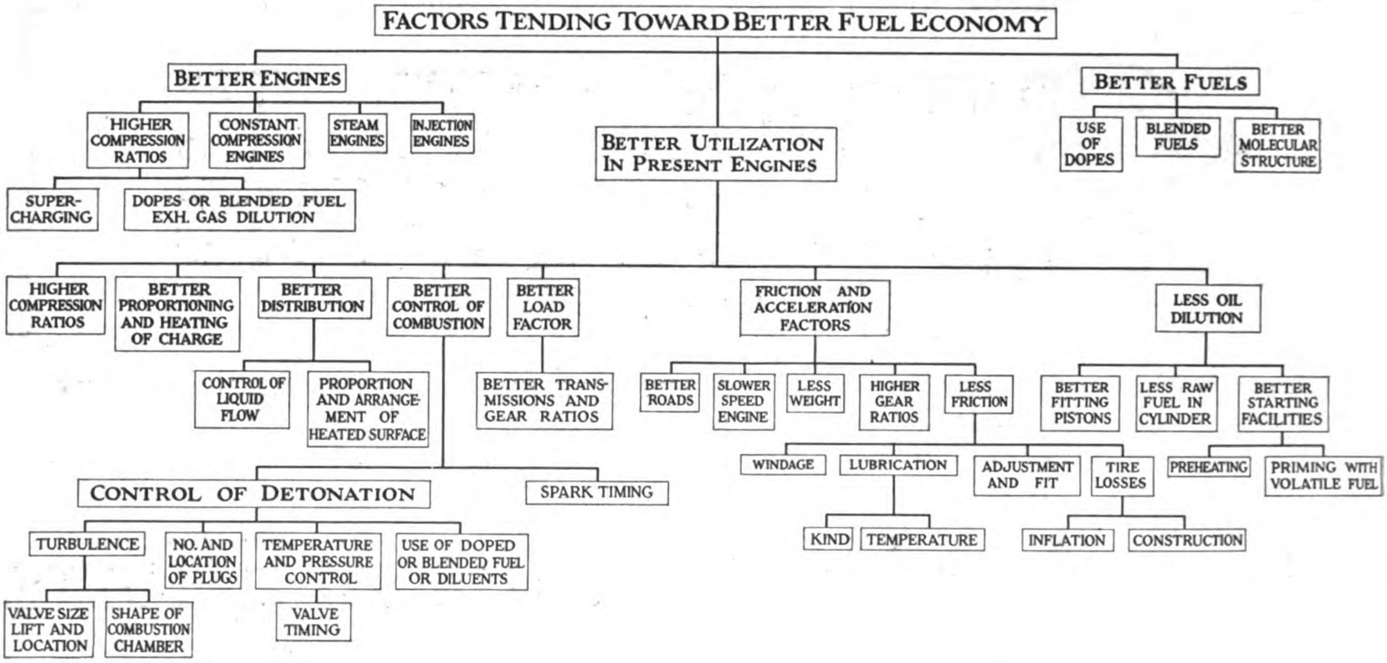
It will be seen from the chart that better fuel economy is to be expected in three main directions as follows:

1. Developing the better engines.
2. Better utilization of fuel in present engines.
3. Development of better fuel.

The work done to date and developments which are in progress or seem promising will be considered under these three heads.

Development of Better Engines

In the chart developments of better engines are classed under four main heads. The first two apply primarily to improvements in the present type of constant volume or so-called Otto cycle engines, while the second apply to other types in less extensive use. The effect of compression ratio on efficiency is illustrated in Fig. 1 from which it will be seen that if it



were possible to use a seven to one compression ratio in a constant volume engine the thermal efficiency would be as high as that of any engine now in commercial use. The chief reason why these high compression ratios are not now employed is the fact that they cannot be used with present fuels without detonation or too early ignition with consequent serious results covered later under another head. High compression ratios have been used in experimental engines with results which have been published by Ricardo* and others. They have been made possible by the use of blended or doped fuels, considered under another head below.

Ricard's super-charging engine has given a brake mean effective pressure as high as 140 lb. per sq. in. This engine gave a brake thermal efficiency of 34 per cent, equivalent to a fuel consumption of 0.461 lb. of fuel per bhp. hr. This was accomplished by the use of cooled exhaust gas as a diluent to prevent detonation.

*Nearly all the papers and reports of tests referred to in this artic'e have been printed in issues of AUTOMOTIVE INDUSTRIES or of the Journal of the Society of Automotive Engineers published since June 1, 1920, and are listed under the author's name in the indices to these publications.

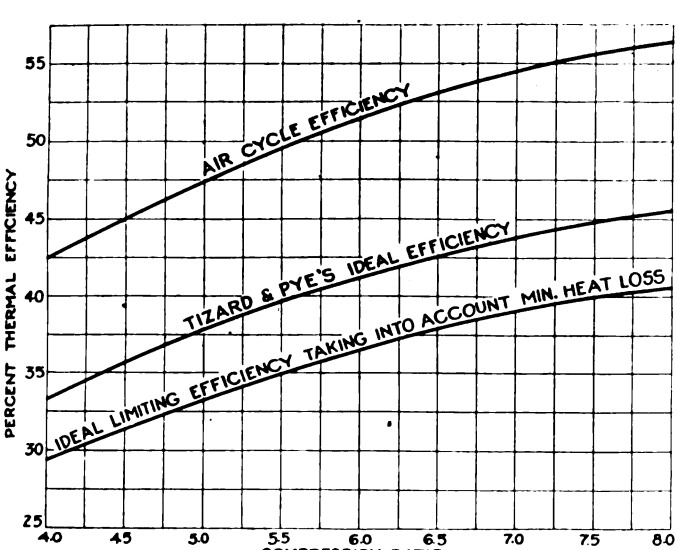


Fig. 1—Curves showing theoretical efficiency obtained with various compression ratios

Constant Compression Engines

One of the inherent disadvantages of the conventional constant volume engine as now generally applied is the fact that when throttled and running at part load its efficiency as compared to full load operation falls off rapidly. It has long been appreciated that if the throttle could be eliminated and the compression held constant while variations in loads are met by changing the quantity of fuel used the efficiency would remain good even though the load is light. This effect is realized to a certain extent in the ordinary two-cycle engine which runs with a practically constant compression and is more efficient at a low load than the ordinary throttled four-cycle constant volume engine. With the ordinary two-cycle engine, however, dilution with exhaust gas at low load is excessive, so that richer mixtures than are otherwise necessary have to be employed. To overcome this disadvantage E. C. Newcomb has long been experimenting with a type of engine illustrated diagrammatically in Fig. 2. This is a two-cycle engine using crankcase compression, but the charge is transferred through a valve in an L chamber in the head. The spark plug is located at the end of the L at a point where a portion of the fresh undiluted portion of the charge always exists at the instant of ignition. The quantity of charge can be regulated by a throttle, but the compression remains constant for the volume of exhaust expelled is determined by the volume of charge admitted, the sum of the two being substantially constant. This engine is said to show a fuel economy of 0.7 lb. per hp. hr. at full load, and slightly less than 0.7 lb. at one-third load. When fitted in a car weighing with passengers about 2000 lb. from 50 to 85 miles per gal. can be covered. This performance is due largely to the fact that the engine is relatively very efficient at part loads, which are the loads obtaining during a large portion of the time, in passenger car operation.

Other experimenters have built engines of the constant compression type operating on a four-stroke cycle. One of these, designed by Ricardo, is illustrated diagrammatically in Fig. 3. This is similar in principle to conventional four-stroke engines except that an extra valve operated by the suction of the engine is provided in a bulb attached to the head of the engine and communicating with the main clearance space through a

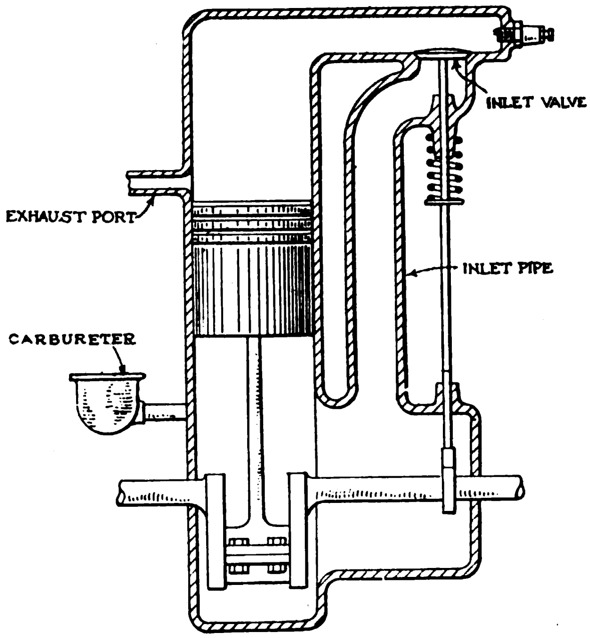

Fig. 2—Diagrammatic view of Newcomb two-cycle constant compression engine.

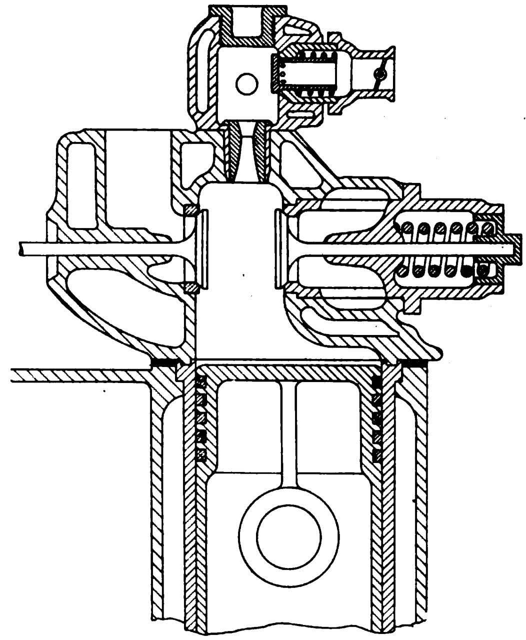

Fig. 3—Diagrammatic view of Ricardo four-cycle constant compression engine

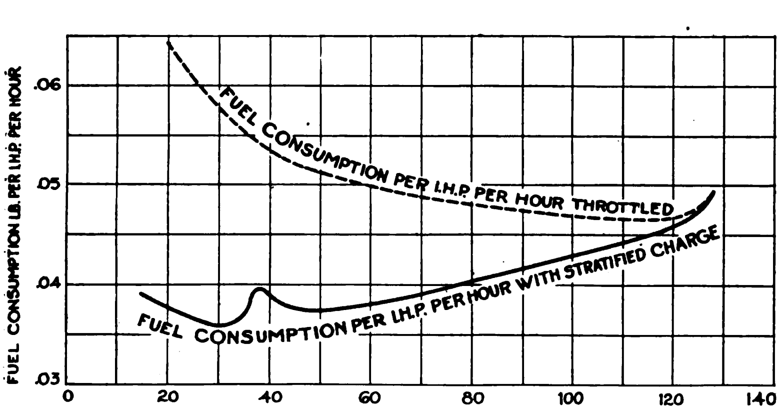
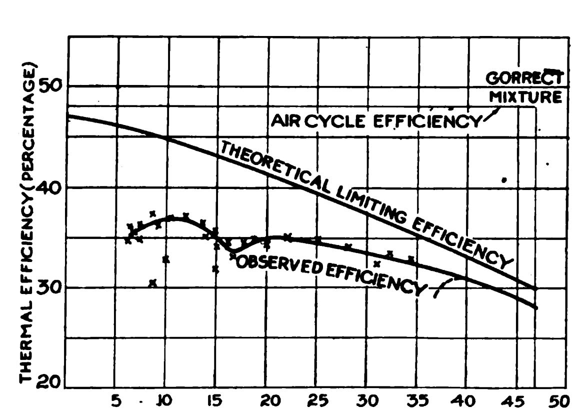
Venturi tube. Gas or rich mixture only enters the bulb on the suction stroke, and this mixture remains in contact with the spark plug in the bulb. Air only is admitted through the usual inlet valve which opens later than the suction operated valve. The rich mixture only is throttled. The air entering through the normal inlet valve fills the remaining space not filled by the mixture of exhaust gases remaining in the clearance space, so that the compression remains constant. On the compression stroke air is forced through the Venturi tube and mixes with the rich gas in the bulb, causing considerable turbulence therein. With this arrangement a localized or stratified charge is obtained. Control is effected entirely by varying the quantity of mixture admitted.

This principle was tried by Ricardo in a single cylinder experimental engine of 5-in. bore and 6-in. stroke. He reports the following interesting results: The engine started easily even in the coldest weather. When running light with an indicated mean pressure of 14 lb. per sq. in. the exhaust, though perfectly free, was almost inaudible. The cylinder barrel remained quite cool and it was possible to bear the hand on any part of a cylinder head or exhaust pipe after an hour's running at no load. So long as the admission of fuel was not altered the speed of the engine remained absolutely uniform. The engine accelerated immediately from a speed of 120 r.p.m. on increasing the quantity of fuel admitted. The violent turbulence resulted in extraordinary rapidity of combustion. Fixed ignition 3 deg. before dead center sufficed for all speeds and loads and invariably gave a vertical line of pressure rise on the indicator diagram. The average of several hundred readings of fuel consumption at all loads from light to full load were taken. The mean results of these are given in Fig. 4 which shows the fuel consumption obtained with indicated mean pressures ranging from 14 to 120 lb. per sq. in. Fig. 5 shows the indicated thermal efficiency actually obtained, the theoretical limiting efficiency and the air cycling efficiency. On full load the running of the engine was in every respect normal.

Subsequent experiments on larger engines could not always be repeated and much further experimental work is necessary before this type of control is rendered generally applicable. Attempts to adapt the principle of operating by stratification alone over the whole range of load to existing engines have not been entirely successful, but have at least been proven that a sufficient degree of stratification can be maintained at the same time with sufficient turbulence to insure rapid combustion, although the two conditions may not at first sight appear compatible. Ricardo proved to his own satisfaction that under these conditions a very marked re-





Performance of Ricardo engine using localized charge. Fig. 4, at left, showing fuel consumption, and Fig. 5, at right, showing ideal indicated thermal efficiency and actual observed efficiency

duction in maximum temperature and a corresponding gain in efficiency could be obtained.

Other experimenters have employed other means for building constant compression engines which do not use the bulb and automatic valve employed by Ricardo. One method of doing this is to make provision whereby the first part of the charge of air entering the cylinder is not mixed with fuel at part loads, the portion of the charge entering later carrying sufficient fuel to meet the load condition imposed. One means for accomplishing this result is illustrated diagrammatically in Fig. 6. This design is due to James A. Charter. A small air pump driven by the engine is arranged to deliver air under pressure to the cylindrical valve driven in timed relation to the engine. By means of the valve and suitable piping air is delivered in the quantity and at the time desired to nozzles placed in the inlet ports of the engine. These air nozzles are so directed as to cause flow of fuel from a fuel jet placed adjacent to the air jet, as shown. The fuel is maintained under constant head by a float mechanism and is fed into the main air stream entering the engine, at the time and in the quantity desired by suitable control of the air passing the air jet, but is not affected by other air entering the cylinder. This control is obtained by axial motion of the distributor valve, which it will be noted has triangular ports. The ports are so proportioned as to feed air through the entire suction stroke at full load or through the latter portion of the stroke only at part load. The charge of fuel is independent of the total quantity of air entering the cylinder, which is substantially constant, but is in direct proportion to the quantity of air fed through the distributing valve and air nozzles. The spark plug is so placed as to be in contact with the carbureted portion of the charge.

Tests of this device are said to have shown considerable saving in fuel both at part and full load as compared with operation with the ordinary carbureter.

Steam Engines

Difficulties involved in adapting present day fuels to use in internal combustion engines has led some investigators to consider further development of the steam engine for automotive use. Newcomb and Scott, among others, have secured commendable results in this direction, and others are experimenting with steam engines. especially for truck and tractor applications. C. A. Norman, who has investigated the possibilities of improved power plants using both steam and internal combustion engines, states that the steam plant, by its ability to handle almost any kind of fuel, its economy at reduced load and its superior maneuvering qualities seems, in many ways, to meet the present fuel situation better than the gas engine.

Injection Engines

One means of realizing the high efficiency obtainable with high compression engines is to utilize fuel injection. The efficiency of this type of engine has long been appreciated and has been realized in practice in the Diesel and other types, but none of these have been extensively utilized to date for automotive purposes, although they are capable of handling low grade fuels. One difficulty with this type has been that involved in handling with precision the extremely minute quantities of liquid fuel required per working stroke in a cylinder of suitable size for automotive use. Practically all engines of this type built to date have been of large size and of very heavy construction. They are also relatively low speed engines, but W. G. Gernandt stated recently that he has developed a single cylinder two-stroke engine of 2¾-in. bore which burns gasoline, kerosene, distillate or fuel oil and can be operated at speeds varying from 225 to 2250 r.p.m. without missing by simply varying the quantity of fuel injected.

Development in the heavy oil engine is continuing and some expect that it will ultimately be adapted to automotive use. The maximum pressures developed even with 500 to 600 lb. compression are said not to exceed the pressures resulting from detonation in engines of conventional types and designs.

Sperry is engaged in developing a supercharging compound expansion Diesel type engine recently described in these columns. This engine weighs, according to Sperry, 27 lb. per hp., but the principles involved are to be incorporated in an aeronautic engine to weigh not in excess of 5 lb. per hp.

The Sperry and some other engines designed for burning heavy fuel are in reality constant volume engines. that is, they burn the fuel injected at substantially constant volume and with considerable rise in pressure above that due to compression. In this respect they differ from the true Diesel engine in which the charge is injected gradually without material rise in pressure. Injection on the compression stroke results in adding area to the indicator card, but, of course, involves higher maximum pressures and temperatures. Newcomb and some others have experimented with injection engines using constant compression pressures, but without the high compression ratio employed in the Diesel type. Engines of this type possess most of the advantageous characteristics of other constant compression engines referred to above, but the difficulty of precise metering of the fuel injected in small cylinders has militated against their success.

Other efforts to develop new types of engines suitable for automotive use but intended to give much higher economies than the conventional types might be cited but space limitations forbid further discussion here.

Many attempts to develop air-cooled engines are now being made, and announcement of these developments is expected before many months. One advantage of this type of engine is the more uniform temperature of the combustion chamber under widely varying operating conditions and the lower loss of heat to the cylinder walls during combustion and the expansion stroke. To date it has not proved possible to use as high compression ratios as have been employed in water-cooled engines, hence economy at full load is not so good as in the latter type. Whether late developments will overcome this disadvantage, or whether the average economy of vehicles using this type of engine will result remains to be seen.

Better Fuel Utilization in Present Engines

It will be noted from the chart at the beginning of this article that there are seven main headings under which improvement in the utilization of fuel in present engines can be anticipated. It is entirely possible that some at least of the advantages referred to already under the head of development of better engines can be made with slight modifications in existing engines or engines of the same or similar types soon to be manufactured. Certain refinements in design, notably those factors controlling combustion to be treated under a later head, may make it possible to use much higher compression ratios than are now generally employed. Such an increase will, perhaps, more than any other one factor, favorably affect the fuel economy of the conventional type of engine, but every item which will contribute to this end should be given careful consideration.

Many investigators, including some of those connected

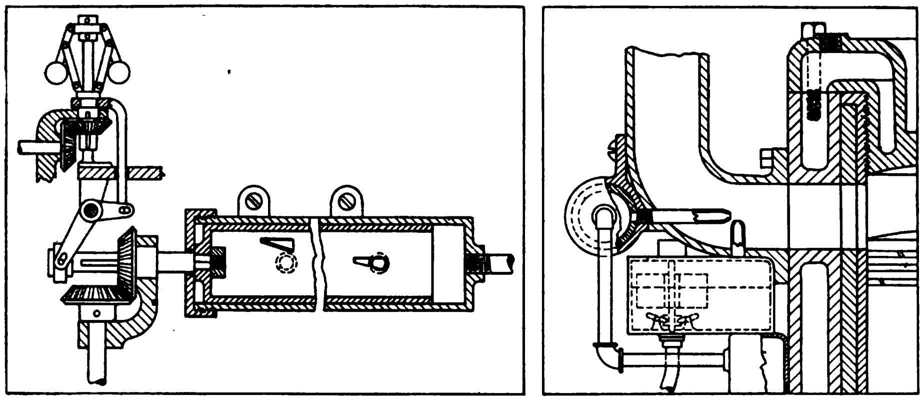


Fig 6—Diagrammatic view showing device used by Charter for timing and measuring charge in constant compression engine.

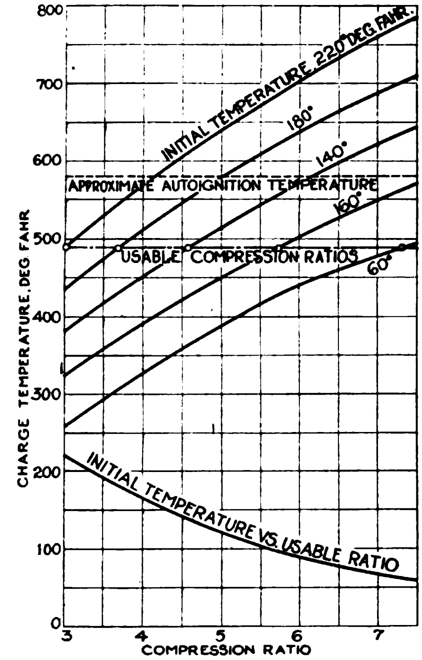

Fig. 7—Curves showing maximum allowable compression pressures with various initial temperatures as given by P. S. Tice.

with the largest automotive manufacturers in this country, are seeking means whereby higher compression ratios can be employed. Kettering is responsible for the statement that if the compression pressure of the conventional engine of to-day could be raised to from 120 to 140 lb. per sq. in. the efficiency would be doubled. Midgley states that in a one-hour run of a Liberty aircraft engine with a compression ratio of 5.3 to 1, using ordinary automobile gasoline instead of high test gasoline at wide open throttle, most of the piston heads were cracked due to detonation while every spark plug was injured. This shows clearly the effect of using with high compression pressures the average fuel now available, unless some means is taken for controlling detonation. This subject will be referred to later, but is mentioned here to illustrate the important bearing which the quality of fuel has in respect to controlling fuel economy. Tests made by Nelson show clearly the effect of higher compression ratios on the economy of one more or less conventional engine. The accompanying cut, Fig. 7, shows the maximum allowable compression with various initial temperatures, as given by P. S. Tice.

Better Proportioning and Heating of Fuel

The importance, as affecting fuel economy, of properly proportioning the air and fuel in the mixture entering the cylinder, and of heating this mixture a proper amount can scarcely be overemphasized. Much research work has been done for the purpose of determining exactly what mixture proportions and temperature are necessary for maximum economy. In this connection James, Dickinson and Sparrow reported the following conclusions resulting from tests at the Bureau of Standards: at constant speed, mixture ratio and power output, the fuel consumption in lbs. per bhp. hr. is independent of the temperatures and methods of heating the intake charge within the range tested. The rate at which an engine will accelerate with a given mixture ratio or carbureter setting is markedly affected by the amount of heat supplied and its method of application. Within the limits of their tests the greater the amount of heat supplied to the charge and the higher its temperature at the intake port the more rapidly the engine accelerated. W. E. Lay reports tests which prove that the mixtures giving maximum economy become leaner as the load increases. The mixture giving best economy at high temperature is leaner than one giving best economy at lower temperature. Thermal efficiency increases as the temperature at the carbureter inlet increases.

Fielder reporting on tests made for the Fifth Avenue Coach Co. shows that average economy is much increased by a device arranged to maintain a constant temperature of mixture even though atmospheric temperature conditions vary between wide limits.

Engineers interested in fuel conservation have often commented on the quite general practice of using rich mixtures as a means of securing rapid acceleration. In this connection Sparrow reports tests in which he found it possible to secure the same acceleration with a heated mixture consisting of 15.3 parts of air to 1 of fuel by weight as with an unheated mixture of 9.4 to 1 proportions. From this it is quite evident that properly heating the fuel effects not only much higher economy but enables good handling and acceleration, factors often gained otherwise by the use of over-rich and extremely wasteful mixtures.

Frank A. Howard has drawn attention to the fact that the ordinary engine gasoline sold to-day possesses sufficient inherent volatility to take and maintain the condition of a gas at a temperature at or below average intake manifold temperatures. Manifold condensation seldom if ever occurs and cylinder condensation is even less probable. Fuel once vaporized must, under the conditions in the manifold, remain a vapor; hence if liquid is found beyond the vaporizer it reached there as a liquid. Manifold condensation, Howard maintains, is impossible with ordinary gasoline above a temperature of about 125 deg. Fahr., because it is physically impossible for fuel vapor to condense when its partial pressure is lower than the determined vapor pressure of the liquid itself at that temperature and this is apparently the average condition in an engine manifold.

Norman calls attention to the fact that heating the air, or the whole charge, will unquestionably give reduced maximum power with the engine on the test-stand. On the other hand it will also make it possible to operate the engine satisfactorily over a greater range of mixture ratio. It is a question whether this smoother general operation is not worth more on the road than an increase of power on the test-stand amounting to perhaps 5 to 10 per cent. In any case, within certain limits, the leanest mixture means the greatest economy and air heating, even up to 250 deg. Fahr., is found to give improved economy by enabling the engine to run on leaner mixtures.

Dickinson points out that not only good operating conditions but good acceleration can be obtained with an economy mixture if the temperature is maintained at about the right point.

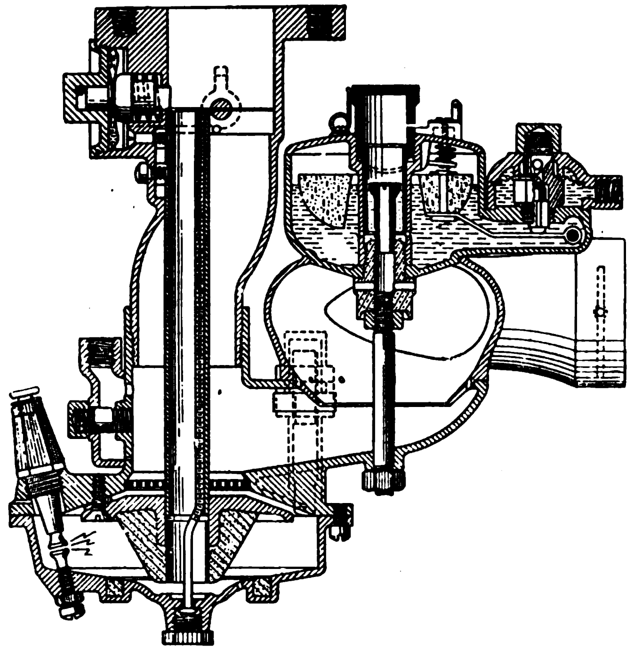

Fig. 8—Ensign fuel convertor.

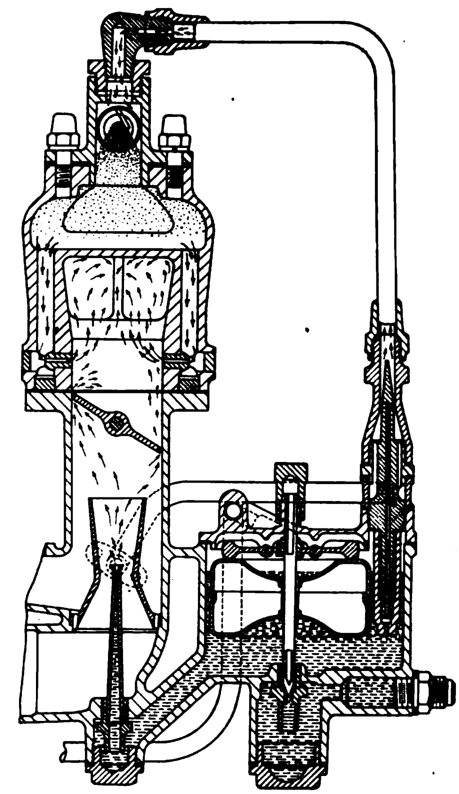

Fig. 9—Packard fuelizer.

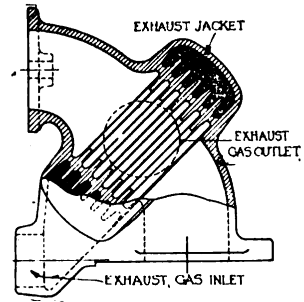

Fig. 11—Section of exhaust heated intake pipe designed by Nelson.

The most general means of maintaining the desired temperature of charge is to apply exhaust heat to the inlet manifold. This subject will be considered under the next heading, manifolding and distribution. One other method of supplying the heat necessary will be mentioned here, namely, that of burning a small portion of the charge for the purpose of heating and vaporizing the remaining portion. Two devices operating on this principle which have seen quite extensive use are the Ensign fuel converter illustrated in Fig. 8, and the Packard "fuelizer," so-called, illustrated in Fig. 9. The Ensign device is so arranged that heavy ends of the fuel not carried out of the carbureter in the air stream are collected below a gauze in the base chamber, together with some air. The rich mixture thus formed in the base chamber is ignited by the spark plug and the products of combustion discharged through the riser tube shown to a point above the throttle where they mix with and heat the remaining charge.

The Packard device is in effect a small supplementary carbureter arranged to function primarily under low throttle conditions, especially in starting. Fuel and air drawn through this device under the high velocity induced by the high vacuum in the manifold is fed to a chamber containing a spark plug where it is ignited. The hot products of combustion flow into the inlet manifold through small orifices above the throttle and thus heat the remainder of the charge. This device is said to overcome the difficulty experienced by some in securing a sufficiently high degree of exhaust heat under low loads to properly vaporize fuel in the charge.

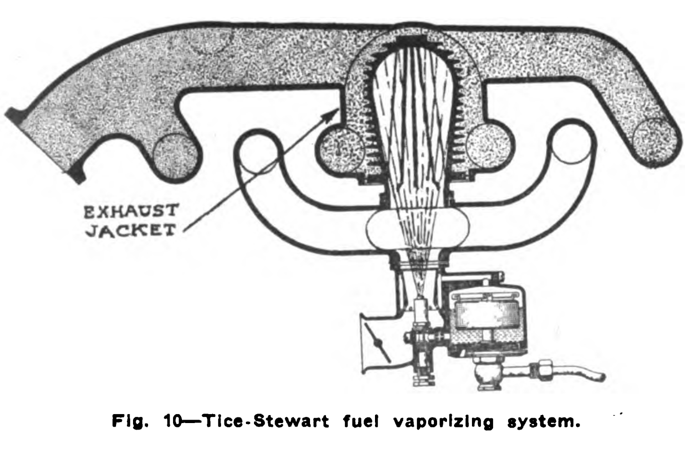

Fig. 10—Tice-Stewart fuel vaporizing system.

Another factor having a marked influence on vaporization is the degree of atomization of the fuel as it leaves the fuel nozzle. Fine atomization increases the fuel surface exposed to heat and thus enables more rapid vaporization. Atomization is facilitated by high velocity at the jet and in some cases by entraining air in the fuel stream prior to its discharge from the jet.

Better Distribution and Manifolding

The problem of properly heating the charge referred to under the previous heading is met in most cases by heating the inlet manifold. This is accomplished in various ways, the heat necessary being secured in most instances by the use of an exhaust jacket surrounding a portion of or the entire inlet manifold. Some investigators are of the opinion that too much heat is absorbed by the charge with a result of excessive rise in temperature when the entire manifold is jacketed, and for this reason most efforts are directed toward heating and vaporizing the fuel without unduly increasing the temperature in the entire charge. This is effected at least to some extent by use of the so-called hot-spot located, as a rule, opposite the discharge of the carbureter or its riser. Many efforts have been made to concentrate heat at this point, but it has been shown that liquid deposited out of the air stream tends to accumulate at the lower side of the manifold adjacent to the T so that considerable heat is required at this point.

Among early investigators who experimented with means for heating the fuel without excessive heating of the air was P. S. Tice, who developed the Stewart vaporizing system shown in Fig. 10. In this the liquid stream issuing from the carbureter is projected into an exhaust heated dome with internal and external ribs which provide considerable surface on which the fuel is vaporized. The vapor then issues into the manifold in the form of a fog and enters the cylinder at a temperature of about 150 deg. Fahr., which is said to remain approximately constant at all loads and speeds.

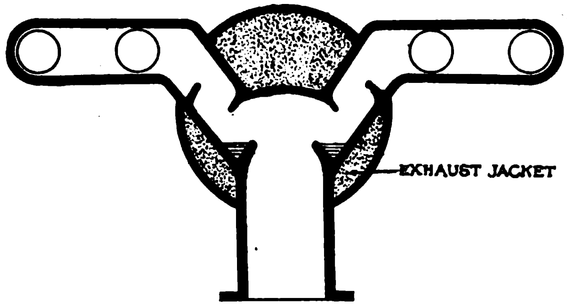

Fig. 12—Exhaust heated inlet pipe designed by Scarratt.

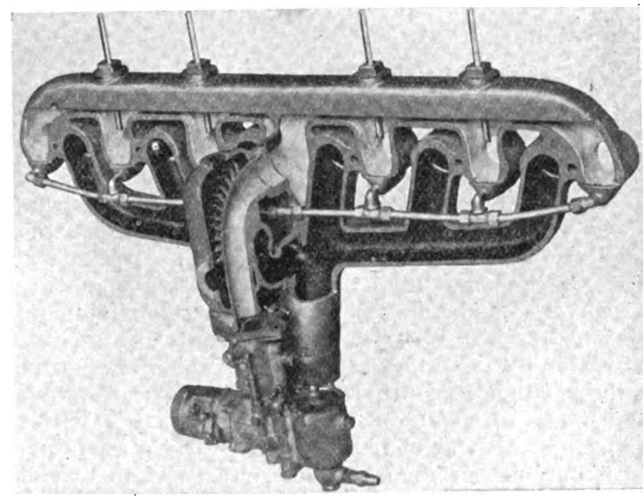

Fig. 13—Exhaust heated intake manifold designed by Dorris.

Other developments along similar lines are seen in the manifolds developed by Nelson, Fig. 11, Scarratt, Fig. 12, and Dorris, Fig. 13. It will be seen by reference to Figs. 11 and 12 that the liquid fuel in both cases is thrown against exhaust heated surfaces. Portions of the fuel not vaporized immediately are deposited out on the hot surface against which they are held under influence of gravity or centrifugal action until vaporized, after which they enter the air stream and are drawn into the cylinders. Fig. 13 shows an exhaust heated manifold so arranged that unvaporized portions of the fuel which reach the inlet ports in liquid condition are deposited out and are returned to an exhaust heated vaporizing pocket where they are converted into a gas and returned to the charge. The average temperature of the charge entering the cylinder in this case is said to be approximately 175 deg. Fahr.

Fig. 14 shows a type of inlet manifold developed by the International Harvester Co. Practically the entire inlet pipe is disposed within the exhaust header, yet according to D. L. Arnold, the charge is not heated sufficiently to materially affect the maximum power developed. The assumption is that the fuel rides the surface all the way round, as indicated by the arrows, thus insulating the core of air. With this manifold the engine is reported to develop 79 lb. brake m.e.p. on 0.6 lb. of gasoline per hp. hr., and with very little knock.

Howard, Mock and other investigators have drawn attention to the need for increasing the time which elapses between discharge of the fuel from the carburetor jet and the entrance of the fuel to the cylinder in order to facilitate vaporization. The Tice, Nelson, Scarratt and Dorris designs provide for this in the manner indicated. These and other designs also provide increased surface for transfer of exhaust heat from the exhaust jacket to the fuel deposited on the other side of the heating surface. By the use of large heating surfaces the temperature of the surface may be decreased. since the quantity of fuel vaporized is a function of time, heating surface and temperature difference, it is evident that all these factors must be considered in efforts to properly vaporize fuel in the charge.

One means of increasing the time element has been suggested by Mock. This involves the use of an expansion chamber with baffles between carbureter and engine. Liquid particles of fuel not vaporized would be deposited out in this chamber and vaporized by contact with exhaust heated walls.

O. C. Berry, discussing tests made at Purdue University, calls attention to the fact that too great an increase in the temperature of the mixture decreases the power considerably and does not increase the thermal efficiency. The mixture temperature giving maximum power in the Purdue test also gave maximum efficiency, and the mixture itself was fairly wet.

Crane, in discussing the subject of distribution, suggests the desirability of making the manifold in the first instance so as to give the best possible distribution without addition of heat and then adding sufficient heat for vaporization. According to his view the manifold should be made as short as possible and should have an upgrade all the way from carbureter to cylinder port. It should be of minimum diameter consistent with power development, and under ideal conditions should be free from liquid on its internal surface. Crane also calls attention to the disturbing effect, especially at low speeds, caused by late closing of the inlet valve, with consequent discharge into the inlet manifold of a portion of the charge already in the cylinder.

Tice and other investigators of the flow of the charge in glass manifolds have shown that liquid tends to accumulate on the walls and travel along them, accumulating, especially at points of low pressure. Dickinson states that distribution and acceleration are largely dependent upon the condition of the manifold surface. Both distribution and acceleration are improved when the manifold surface is relatively dry. James states that tests made at the Bureau of Standards indicate that a much closer study of conditions which determine ability to accelerate rapidly are needed.

From the foregoing analysis of factors affecting the vaporization and distribution of the mixture it will appear that much fundamental data bearing on this subject has been secured. Designs making use of this information are already in use, but much more development work is necessary to improve the performance of the average present day car. A test made on a large number of cars and trucks by the Bureau of Mines indicate that the average car under average operating conditions fails to burn from 20 to 30 per cent of the fuel fed through the carbureter. This enormous waste is the result of inaccurate metering of the fuel and air, incomplete vaporization,

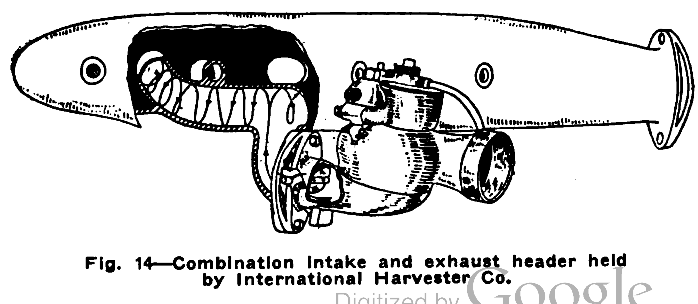

Fig. 14—Combination intake and exhaust header held by International Harvester Co.

poor distribution and mixing, resulting in incomplete combustion.

Control of Combustion

We have already seen that one of the most serious limiting factors in securing better utilization of fuel is the tendency of present day fuels to cause knocking of the engine. The precise cause of this phenomenon is not known, but is presumed to be due to detonation of the charge or portions thereof with accompanying development of extremely high pressures. Tests made at the Bureau of Standards have shown that maximum pressures of at least 1300 lb. per sq. in. are attained when detonation occurs under certain conditions. Experiments made by Dixon and others show that the rate at which flame travels through a combustible mixture varies in steps from the time of ignition. During the early period of combustion the flame is blue or green and travels at a relatively low constant speed. During the next period the rate of travel accelerates rapidly and the flame becomes yellow until it attains a constant and very rapid velocity which is termed detonation. The flame is usually white during the detonation period and the liberation of energy is extremely rapid.

If in a given volume of mixture the entire charge can be ignited before the flame has had an opportunity to attain the detonation velocity, detonation does not occur. It is possible to control detonation by at least four methods, as will be seen by reference to the chart at the beginning of this article. In this connection as Horning, Ricardo and others have pointed out turbulence of the charge is an extremely important element. If at the moment of ignition the charge is swirling or in rapid motion the flame is quickly spread to many points in the mixture. This is practically equivalent to igniting the mixture simultaneously at many points. Under these circumstances the flame has a minimum distance to travel and consequently does not have time to attain the detonation velocity.

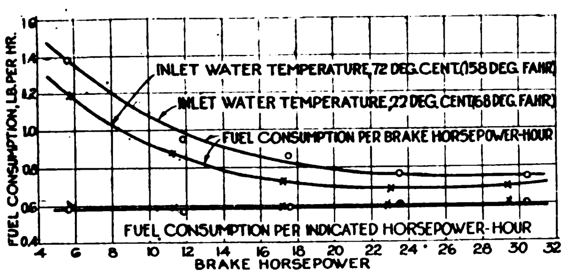

Fig. 15—Curves showing the increase in fuel consumption per brake hp. due to increased frictional losses, attributed to higher oil viscosity, at low as compared to high jacket temperatures.

There are two methods of creating turbulence in the combustion chamber. The first is to so locate the valve and proportion its size and lift that the charge, entering the combustion chamber at high velocity, is given a swirling motion which continues during the compression stroke and ignition period. To do this the combustion chamber must be so shaped as to minimize eddying and the velocity necessary through the valve must be so great as to limit the volumetric efficiency to a value lower than is otherwise necessary. Horning's recent paper on the subject of turbulence shows shapes of combustion chamber such that the gases being compressed in the clearing space are caused to move at high velocity, thus positively creating turbulence. This result is accomplished without unduly limiting the valve area and constitutes the second method of creating turbulence.

The second means of controlling detonation referred to in the chart is to so place the spark plug or plugs that the flame will have the shortest possible distance to travel. This is accomplished with a single plug when the plug is placed as near as possible to the center of gravity of the mixture. The use of two or more plugs properly placed and fired simultaneously further minimizes the distance to be traveled and may to some extent compensate for lack of turbulence.

Detonation is known to be controlled to some extent by pressure, and according to Midgely, Tice and others is greatly affected by temperature. Ricardo attributes detonation to the following phenomena; a combustible mixture in a closed chamber is ignited and the flame starts to travel from this point. The combustion raises the pressure of the gases burned and as a result the remaining unburnt gas is compressed and heated until finally it reaches the auto-ignition temperature and the entire mass is set off simultaneously. It will be seen that if the gas is already heated by contact with the piston head, exhaust valve or other hot parts of the combustion chamber, its auto-ignition temperature is more quickly reached. For this reason it is desirable to create turbulence which tends to equalize the temperature of the entire charge. It is desirable also to so design the piston, exhaust valve, spark plug and any other parts that may easily become overheated in such a way that a maximum of cooling results. Horning and others have pointed out that it is desirable to place the spark plug so that ignition will take place at a minimum distance from the hottest point. It should also be placed in the path of greatest turbulence and in, rather than opposite to, a pocket in the combustion chamber.

The pressure of the gases at the time of ignition is controlled primarily by the compression ratio, but can, as Nelson has pointed out, be controlled to some extent by variation in the valve timing. It is a matter of common knowledge that most engines tend to knock more readily at low than at high speeds. If then the compression pressure can be reduced at the lower speeds the tendency to knock will be less at these speeds. This is accomplished by employing a late closing of the inlet valve. At low speed some of the charge drawn into the cylinder is ejected again before the valve closes, while at high speeds this tendency is overcome by the greater inertia of incoming gas. This method of control, according to Nelson, makes possible the use of higher compression ratios than are otherwise useable.

Another important means of controlling detonation discovered and developed by Kettering and Midgley involves the use of so-called "doped" fuels. Small quantities of iodine and anilin among other substances have been found to control, at least within certain limits, the tendency of a fuel to knock, and much experimental work has been done with a view to developing a dope which will be readily available commercially and if possible be added to the fuel during the refining process. It is certain that if such a substance is found and generally employed far higher compression ratios can be used and correspondingly higher thermal efficiency attained.

Extensive research work initiated and conducted by Kettering and Midgley has shown that various classes of hydrocarbon fuels with different molecular structures have widely differing tendencies to detonate. Ethers have the greatest tendency to knock of the more common hydrocarbons, while the alcohols have the least tendency. Midgley was the first to arrange the common hydrocarbons in the order of their tendency to knock. He gives the following table of hydrocarbon fuels arranged in

order of tendency to detonate and giving the disadvantages of these fuels in other respects:

Fuels	Disadvantages
Ethers	Pre-ignition
Paraffins	None, if volatile
Olefins	Polymerize and stick intake valves
Naphthenes	None, if volatile
Aromatics	Form fluffy carbon
Alcohols	Low heating value

Ricardo has attempted, as reported in articles by him printed in these columns, to go a step further and assign to the various fuels a definite knocking value, but for reasons which cannot here be discussed there is reason to question the value of some of the results obtained, though in the main they probably serve a useful purpose.

Many tests on blended fuels, such as mixtures of gasoline and benzol or gasoline, benzol and alcohol, have been made with a view to counteracting knocking tendencies and other disadvantages. The value of fuels of this character is limited to some extent by lack of sufficient quantity for general use and means for general distribution. It has been definitely proved, however, that some fuels can be greatly improved by blending and for this reason it seems probable that such fuels will be more generally used in future than has been the case to date. The use of blended fuels enables the use of higher compression ratios and consequently higher economies in engines designed for their use.

The use of excess air or inert gas, such as products of combustion, as diluents to prevent detonation, has already been touched upon, and it seems probable that their use will increase in the future. The use of diluents may decrease the maximum output of engines of a given size and weight, but this detrimental effect can be partly if not wholly offset by the use of higher compression pressure and consequent higher mean effective pressures, while the thermal efficiency can be considerably increased. There seems to be great promise in this field which will doubtless receive much more general consideration in the near future.

The effect of spark timing on the control of combustion and the resultant effect upon economy has been investigated by Sparrow, Grimes and others. It has been customary to use extensively devices which increase the spark advance with speed. There is need for further consideration of means for securing the most effective spark advance with change in load. As the load decreases greater spark advance can be employed to advantage from the standpoint of better economy, and it may be possible to more or less positively control spark advance in relation to load. In any case this is a matter worthy of further consideration.

Better Load Factor

It is a well-known fact that the efficiency of the ordinary throttling Otto cycle engine falls off rapidly with decrease in load (see Fig. 15), and it is unfortunately true that the average driving condition in the case of the usual passenger car is one of low load operation under which the economy is necessarily poor. Anything which can be done to better the load factor will of course result in increased economy, but will under the usual circumstances correspondingly decrease what is generally called high gear ability. The advantages of high gear ratios in respect to load factor have been pointed out by Nelson and the disadvantages must also be taken into consideration. Nelson shows in one case that a change in rear axle gear ratio from 4.5 to 1 to 2.5 to 1 resulted in a maximum increase in the brake thermal efficiency of 53 per cent at 29 mi. per hr. car speed and 48 per cent at 10 mi. per hr. Gains in efficiency of this order should not longer be overlooked. While it is no doubt true that the American public objects to gear changing, which becomes more necessary as the gear ratio is increased and the car ability correspondingly decreased, many believe that means can be found to overcome this disadvantage by changes and improvements in transmission design. It is suggested in this connection that the possibility of two-speed axles be further investigated, the lower gear to be used in traffic and when maximum car ability is required and the higher gear as much as possible under average driving conditions. With the noise and general aversion to use of the lower gears of the transmission thus reduced and higher economies made possible, it is believed that such complication in mechanism and control as would be involved would be much more than offset.

The possibility of decreased total weight of vehicle in connection with its relation to gear ratio and load factor should also receive further consideration.

Friction and Acceleration Factors

The effect of friction and acceleration factors upon fuel economy has been much discussed, but too little heeded. There are many factors which contribute to the frictional resistance to motion of the car. The use of proper lubricant, especially the substitution of oil for grease in the transmission and rear axle, assists in materially reducing friction, as does also the proper selection of bearings and the fit and adjustment of bearing parts. A considerable proportion of the frictional loss in a car lies in the tires. Greater improvement in this regard has been made by the development and much more extensive use of cord tires, which absorb far less power than the ordinary fabric type. Tests by E. H. Lockwood show that the power absorbed by the fabric type exceeds by as much as 100 per cent that absorbed by the cord type. Inflation pressures also have a bearing upon frictional loss, the loss decreasing as the inflation pressure increases.

Lubricants, especially that used in the engine, should be selected with due regard to temperature conditions during operation. Sparrow has shown that, while the fuel consumption of an engine per indicated horsepower-hour remains substantially constant with change in temperature of jacket water, there is a very material difference in the fuel consumed per brake horsepower-hour, due to the much higher viscosity of the oil at low temperature. See Fig. 15.

The loss of power due to dragging brakes has often been mentioned in discussing frictional losses in cars, but much opportunity for improvement still exists in respect to the design of brakes which will not drag. The external band brake is a serious offender in this connection, and for this and other reasons is fortunately being abandoned on many cars.

Sparrow, in discussing the relative merits of large slow speed and small high-speed engines, shows that the former type is the more efficient relatively, due to the fact that friction losses increase materially with high speed. Frictional power losses increase to some extent as the load on the engine decreases at any given speed. This is one reason why the economy of the ordinary throttling engine decreases rapidly as the load decreases. James quotes figures which show in one case that, whereas only 2.85 hp. is required to propel a certain car on a level road at 20 miles per hour, the friction horsepower in the engine under these conditions amounts to 3.51 hp., showing that, under what may be regarded as ap-

proximately an average operating condition, a very large percentage of the fuel consumed goes simply to overcome frictional losses in the engine. These losses can be minimized by the use of larger and slower speed engines with proper gear reductions and a better power factor, as already pointed out. Here, again, the advantage of using a non-throttling, constant-compression engine, already referred to, is worthy of consideration.

The power absorbed in overcoming air resistance is not very great at moderate speeds, but increases with the square of the velocity and, therefore, becomes a large factor at high speed. This loss cannot be avoided, but can be minimized by reducing, so far as is practical, the frontal area of the car and improving the streamline form.

Frictional resistance to the motion of the car on the road is a function of the nature of the road surface and is a minimum on hard, smooth surfaces. It will thus be seen that good roads are an important factor in relation to fuel economy. Considerable saving in power and fuel can also be effected by proper road grading.

Gear ratio and weight are factors which, together with the power available, control the rate of acceleration of a given car. The lower the weight the higher the gear ratio that can be used for given power and the less fuel is consumed in acceleration and climbing.

Oil Dilution by Fuel

Less oil dilution by fuel, the last item listed in the chart at the beginning of the article, under the heading of better utilization of fuel in present engines, refers to dilution of lubricating oil in the crankcase by fuel passing the pistons. The waste of fuel in this respect, while not a large element in the total fuel consumption of a car, has a very serious effect upon the operation, wear and other factors, and results in waste of lubricant, for which there is as much need for conservation as there is for fuel conservation. Oil dilution can be minimized by the use of better-fitting pistons and rings, by better vaporization of the fuel during normal operation, with a minimum of raw or unvaporized fuel allowed to enter the cylinder, and by avoiding the use of the choke and other devices providing excessively rich mixtures for starting.

Better-fitting pistons and rings are secured by careful machine work and selection of well-mated parts in assembly. Better means for fuel vaporization have already been considered. The practice of using the choke or an over-rich mixture for starting is very general and results not only in the direct waste of fuel but in feeding into the cylinder raw liquid fuel, a portion of which invariably finds its way past the pistons. This loss can be minimized, if not entirely prevented, by the use of some pre-heating device, such as the Packard "fuelizer," or by the use of some very volatile liquid, such as petroleum ether, for priming. In the latter case exhaust heat resulting from the first few explosions in the cylinder provides means for vaporizing the fuel entering later in the normal way through the carbureter.

The Possibility and Advantage of Better Fuel

The items thus far enumerated as bearing upon the subject of better fuel economy are in large part subject to control by the automotive industry, or are of such nature that their solution can and should be sought by this industry. The problem does not end with the automotive industry, however. It is quite as important that the petroleum industry use its best effort to provide fuel that will so far as possible lend itself to most efficient utilization. It will not suffice to take the attitude that nothing can be done by the fuel industry save to furnish products obtainable from crude petroleum by direct and simple distillation processes. Much increase in gasoline production has resulted from the introduction of cracking processes which change the molecular structure of the fuel. It has been conclusively demonstrated by Midgley and others that certain other molecular changes in the average fuel produced would much better suit it for efficient use. The possibility of doing this must not be overlooked, even though it involves large investment in cracking stills or other equipment.

Crane is responsible for the statement that it is impossible to build a simple automotive engine which will effectively and efficiently handle, under all operating conditions, even the fuels at present available. Reasonably satisfactory operation is obtainable by the use of more or less complicated vaporizing devices, but even then really good economy is not secured, and the more complicated the device the more difficult becomes its use in the hands of the average vehicle operator. Horning, Crane and others have pointed out that portions of the fuel which distil at temperatures in excess of 400 deg. Fahr. are more or less useless and lead to difficulties in oil dilution, etc., which render them decidedly objectionable. Tests made by Sparrow indicate that increase in end point leads to direct increase in fuel consumption. In spite of these facts, the end point of commercial gasoline has been increasing for many years, and but little effort appears to have been made by the petroleum industry to maintain it within suitable bounds.

It is a well-known fact that the use of benzol, alcohol and other substances with gasoline make it possible to use the latter with much greater satisfaction and efficiency than when the gasoline is used alone. Unfortunately, neither benzol nor alcohol are produced in sufficient quantities to make it possible to use them as blending agents for even a large proportion of the gasoline now produced. Nevertheless, their production and use should be encouraged and steps to determine whether other blending agents forming a part of crude petroleum, or easily derivable therefrom, cannot be produced in sufficient quantity to be used to materially improve present-day gasolines.

This brings us to the important subject of the use of so-called "dopes." As already pointed out, Midgley and others have definitely demonstrated the advantage of using certain dopes. Efforts to find a suitable dope which can be produced and used in the normal process of refining are under way and should receive more general consideration. If, as seems entirely possible, it proves to be commercially feasible to produce fuels which will be free from the knocking tendency even under high compression, the available supply of crude petroleum can certainly be made to go much further than it will go if present methods and qualities of fuel are generally maintained in the market.

There is certainly great need for further and more effective co-operation between the automotive and petroleum industries with a view to producing both engines and fuels which will result in the most effective net result, to the end that our natural fuel resources may be conserved and utilized to the best advantage.

It will be seen from the foregoing that the fuel problem is exceedingly complex and must be made the subject of much further and more extensive research work. The co-operation attained to date in this direction in the automotive industry is highly commendable. It would seem that the petroleum industry has been less progressive and energetic in seeking the solution of the fuel problem, at least in so far as the public has been informed. Every effort should be made to bring about a better mutual understanding of existing problems.

FACTORS AFFECTING DESIGN

Advantages of Contact with the Vehicle in Road Use

No test is so likely to indicate weak points in a vehicle as road use. Every owner should be made a member of the factory experimental department. The results of such a policy are an invaluable aid to the engineer in making new designs and in correcting faults in old models.

By J. Edward Schipper

EVERY owner of a car or truck should be, figuratively speaking, a member of the factory experimental department. Viewed from that standpoint, every car on the road is a test car. Every trip made by an owner is a test trip. Every mishap pays for itself by the fund of data it supplies the factory metallurgical and engineering departments.

To realize fully this ideal situation would be an involved and expensive proceeding. There is no reason, however, why a high percentage of this information cannot be rendered available to the factory executives and engineering department in every automobile and truck plant. In fact, a great many companies have systems by which they are accomplishing this end, but very few, if any, are going into the matter as thoroughly as should be done at this stage of the industry.

To get this information into the hands of the proper people at the factory, it is necessary that the proper system be employed. The matter must be made a routine work, so that an uninterrupted flow of reports on cars in owners' hands is continually coming into the factory office. There are several methods of doing this, some of which will be described herewith, employed by various concerns in the passenger car and truck fields. Many of these are capable of further development and form the nucleus of a system which, if amplified, would reach the desired efficiency.

Use of Service Reports

In bringing out an improved series of a current model it is customary to utilize the reports turned over to the engineering department by the service manager. This is common practice in all concerns and it is by necessity that the cars on the road offer the direct information as to what improvements are necessary in models which are going through production. The reports that the service manager turns over to the engineering department, or which reach the engineering department by way of the metallurgical department, which has investigated broken parts turned over to them by the service department, are complete or incomplete in accordance as to whether or not the proper contact is maintained between the factory and the cars which are out.

There are always a certain number of parts coming back in the way of policy replacement. These are replacements made by the dealer to the consumer without charge, and in order to receive credit from the factory the dealer has returned them with a claim. This claim is investigated through the metallurgical or other departments concerned and the claim allowed or disallowed. At the same time information is gathered which is of benefit to the engineering department and which is so utilized by every factory in the business which makes any pretense of systematically organizing its affairs.

It is possible and necessary to go much further than this in order to maintain the proper contact with the cars which are out in the owners' hands. The policy replacement involves parts which are broken only during the three months' guarantee period. There are a number of other parts, however, which are broken after this period has expired and of which in many cases the engineering department at the factory is never informed. This is neglect of a source of information which is of the highest value in determining future dimensions, material specifications and structural design of future parts. To state the matter simply, there is not sufficiently direct contact between the owner and the plant. The owner has not been made a member of the experimental department. His car is not a factory test car.

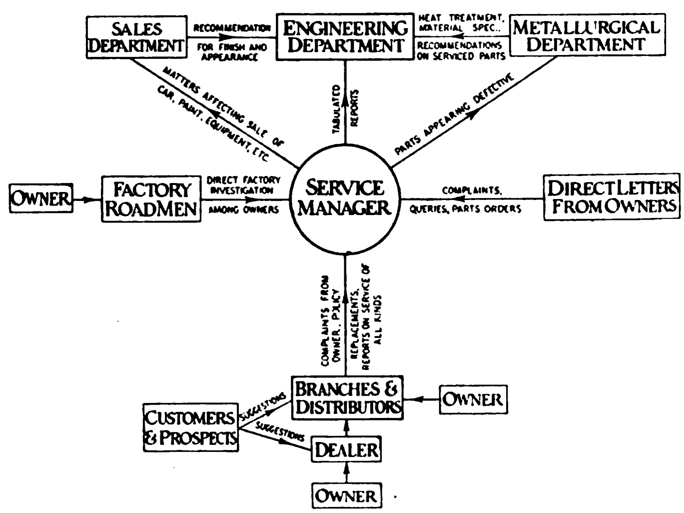
The Method

There is no one best method for keeping this contact. The method employed depends very largely upon the size of the organization and its output. A very good example of how this work can be carried out by a large organization is the method employed by the International Harvester Co., in following the fortune of its trucks in the hands of the owner. This organization has 100 factory branches through which its sales and service on trucks are handled and supervised. Each of these factory branches has what is known as a road engineer, whose sole duty it is to inspect the trucks in use in his territory. He is constantly on the road, going from one owner to the next, going over every one of the trucks in his territory, so that every truck the International Harvester Co. has in the field receives three to four inspections a year by these road engineers. A report on every truck is made up by the road engineer and forwarded to the service manager at the factory. It is the duty of the service manager at the factory to act as a clearing house for all of this information and to properly tabulate it and send it to the engineering department. By complete card index systems a record of every truck out is available.

It is possible to picture the tremendous amount of in-

formation that the engineering department has with a system of this kind. In his talk with the owner of the truck the road engineer is, of course, informed of every mishap which has occurred; he knows the service each particular truck has been giving and this information, coupled with the territorial peculiarities of the country in which the truck is operating, gives immediately a view of the service ability of that particular kind and size of truck in that particular country and on that particular kind of work.

This vast system could, of course, be only employed by a very large organization. To carry 100 road engineers on the payroll of a concern means a large annual expenditure, which could not be carried by any moderate size organization. It shows, however, the length to which a large and well-managed concern is willing to go in order to keep in touch with the vehicles in the users' hands. A continuous flow of priceless information is continually coming to the plant from every truck which it has turned out and puts into the field. By properly tabulating and charting these complaints and records, it is easy to see that the International Harvester Co. knows whether or not each part in its truck is properly designed; whether or not it has the proper material with the proper heat treatment, and every bit of other information regarding it which is necessary to determine whether or not to continue that particular feature in future designs.



Service Manager is clearing house for valuable engineering data.

The sales value of such a system must not be overlooked in considering the benefits which accrue from its use. When an owner of a truck is approached three or four times a year by a factory inspector and his vehicles given a thorough going over, with recommendations as to repairs, etc., it is easy to see that this owner is going to be impressed by the service he is receiving. When he buys another truck he is very apt to purchase one of the same make when such attention is given. The International Harvester Co. sold more than 6000 trucks during 1920, and did a gross business of over $9,000,000 in its truck department. In spite of the depression in the truck business generally, its quota to dealers has been practically as large for 1921 as for 1920. Is it not likely that this continuation of business has been largely due to this intimate contact between the factory and the car in the user's hands? In other words, the engineering department is not the only one which profits through the contact.

The Packard Motor Car Co. operates through a different system. At the factory there is a service engineer who makes periodic trips to the various distributers, talking directly with their technical men. These technical men are in the employ of the distributer and in this case act as the eyes of the organization and as the contact point with the owners of the Packard cars and trucks. The service engineer also takes care of all the complaints which come by mail to the factory and he also keeps a strict tabulation on all returned goods. These are tabulated under the head of the particular part and are so kept that at all times it is possible to see if the percentage of returns on any given parts are running above normal.

The keynote of this system is, of course, the technical man and the way he is handled by the distributer. If he is kept continually on the go and circulating among the owners' cars and trucks, he is an exact parallel with the road engineer, as described under the International Harvester system. On the other hand, if the technical man is an inside man, his contact is maintained only when trouble develops. In either way, however, he is the man who secures the reports on the cars and trucks on the road, and he files his reports with the service engineer at the factory who keeps in continual touch with him. The technical man makes frequent trips to the factory and thus acts as a direct go-between, connecting the manufacturing organization with the owners.

A monthly analysis of trouble complaints is made by the service engineer. He charts these under the monthly record head as number of complaints made, number investigated, number remedied. Then, in further detail, the cause of the compaint is noted and the remedy applied or suggested for future designs is entered. Under the subhead of how remedied, there are four classifications. These are:

(a) future design;
(b) manufacturing methods;
(c) metallurgical treatment, or
(d) educational campaign.

The educational campaign is started when it is found that certain troubles are developing, due to the misuse or improper driving of the owner. For instance, if a number of complaints are coming in on the clutch, indicating that owners are slipping the clutch too much in driving, and although it has been found that the clutch is perfectly satisfactory when properly used, that there are an abnormal number of complaints upon the clutch, an educational campaign on proper use of the clutch in driving would be started.

In addition to the technical men of the distributers, the factory itself has a number of technical men who go out among the owners and find if proper service is being given and if the cars are giving proper satisfaction. This is merely a check-up on the service, however, and has nothing directly to do with the communication between the factory and the car owner from a report of the cars on the road standpoint.

To give another example of the systems in use by the different concerns, the Hupp Motor Car Co. uses the distributer as the connecting link between the car on the road and the factory. When an owner comes into the distributer's service department with a complaint a careful record is made and is forwarded to the factory, where it goes to the service manager's desk. A copy of every complaint which comes in is sent to the engineering department and if it seems serious enough to the service engineer, a copy is also sent to the president. If the matter affects sales, such as complaints on the finish, etc., of the car, copies of these complaints are also sent to the sales department.

These three systems of operation are typical of those employed by manufacturing concerns to-day to keep a

contact between the factory and the cars which it has produced. The service manager at the plant is, of course, the man who must organize this system of contact and he therefore becomes a very prominent and important official in the organization if the work is carried on as it should be. It has not been the practice in very many organizations in the past to call in the service manager on an entirely new design. He is consulted, of course, on changes and, in fact, most changes come as a result of his reports and recommendations to the engineering department, or as the result of recommendations to the engineering department from the metallurgical end of the business, because of specimens or samples turned over to the metallurgical department by the service manager. Consequently, on revised models, he has been always consulted.

The day has now come, however, when the service manager should be taken into conference on entirely new models. There is no reason why the fund of experience which has come as the result of contact with thousands of owners' reports should not be used in just the same degree as the reports from the experimental engineering department, which secures the data from test cars on the road and the laboratory. The owner is an enthusiastic investigator. The car is a part of his daily life. After a few months or a year of driving, he becomes so intimately acquainted with his car that its slightest symptoms become apparent to him as quickly as it would to a trained observer. The factory wants to get the information at the disposal of this man. It can get it by carefully systematizing the work and by properly charting the complaints and information he passes along.

Watch Expenses

It would be advisable at the factory to divide this information and record it in almost the same way as the parts themselves are recorded; that is, by keeping the records in accordance with the parts numbers and filed under the head of the parts numbers, the information is immediately usable in every department of the factory. At the same time, when a part is to be changed, the record on that particular part as compiled from the service manager's reports, which, of course, have originated from the owner, are all listed under the number of the part under consideration. This immediately renders available a fund of information on the part under consideration and should be one of the main factors in preventing "bugs" in entirely new models, as well as making future models better than their predecessors.

The great point in installing a system of contact between the owner's car on the road and the factory is that the system utilized for getting the information into the proper hands at the factory shall not be too expensive. If an expenditure of from $2 to $5 per car is allotted for this purpose, depending on the quantity of output, a very complete and thorough system can be installed by factories having anywhere from a moderate to a heavy output. The practice of having road men out among the owners cannot be considered as expense without return, because a good road man will more than earn his keep by the amount of business he turns over to the service department. He will recommend certain definite repairs and will save the car owner money, because he will catch little troubles before they grow into big ones. He will make money for the organization by which he is employed, because he will direct the car owner to the service station instead of to some miscellaneous garage doing work for all classes and makes of cars.

Also, he brings money back into the business by his intimate contact with the owner, through which he tends to keep the owner satisfied with the product. Consequently he can be considered as doing some real, advance sales campaign work. When a man has been visited by a good factory road man and has become impressed by the fact that the organization which manufactured his car is interested in seeing that it gives him good service, it is unlikely that he will purchase any other make of vehicle when he buys subsequently. This applies to trucks as much as or more than it does to passenger cars.

The amount of data which, coming into the engineering department, is of definite use as material for determining on future design problems is difficult to reckon on a dollar and cent basis. When the amount of money which can be spent through an experimental department is considered, however, it is certain that this information is of the highest value and, furthermore, is much more complete and authentic than possibly could be secured from an experimental department. In the first place, the cars are in the hands of the type of driver which will operate the new product. Reports are secured from all localities of the country and consequently abnormal conditions in any one locality show up very readily. There are numerous examples of the effect of local conditions.

Not long ago, The Hupp Motor Car Co. noted that the high road speeds of California put an added duty on the cooling system of the car because uninterrupted travel at high speeds was more general in this particular locality than in any other. The speed laws permit of higher speeds and the roads are wide and straight. Complaints from the owners, which passed back through the dealer and then to the factory, gave an intimate knowledge of these conditions and allowed of slight alterations in the cooling water capacity to take care of the abnormal conditions. This would never have reached the factory except for the good system of contact with its owners.

Local Conditions

Another abnormal local condition has been noted by certain manufacturers around Birmingham, Ala. It has been found that the timing chains tend to etch more rapidly than elsewhere. Investigation has shown that the extensive use of benzol in this locality has caused, particularly in the winter time, a notable sulphuric acid content in the lubricating oil. This has acted upon the surface of the chain, setting up an electric current which has been sufficient to cause very marked chain etching and consequently to shorten chain life.

These facts have been brought to the attention of the engineering department by keeping close contact with records of the cars in owners' hands. There are literally hundreds of these abnormal conditions which prevail in different parts of the country and which it is almost impossible to foresee in the engineering department or experimental laboratory. The only reliable and sure way of finding out these conditions is by the proper contact with the cars which the factory has out. Consequently, it is advisable for a plant to make a study of the problem from its own individual standpoint, as the number of cars on the road will have a great deal to do with the way in which the system is worked out. The three examples given herewith of the International Harvester, Hupmobile and Packard factories suggest three systems which have proved successful. Any concern which has been in business for a year or more should adopt something along this line in order to reap the full benefit of the experience without which it is impossible to improve design readily.

FACTORS AFFECTING DESIGN

Engineer's Work Definitely Related to Human Element in the Plant

In many points of design, the engineer is limited by the abilities of the various human beings within the plant. The average accuracy of work will affect the tolerances while the cost of supervision is also a factor.

By Harry Tipper

THE purpose of the designing engineer in laying out the working drawings of his product is to express in that design the best practice compatible with the working conditions in the organization. It is the work of the engineer to include in his design improvements calculated to increase the service of the product, and in suggesting these improvements they must be measured necessarily by the possibilities of their practical development within the productive organization.

The development which the engineer can make is, therefore, limited by the practice among the supplies of raw material, machinery, and so forth, his knowledge of that practice, the application of the pure science in the actual production work and his observation in connection with it; the practice within the plant in all the elements of production, the accuracy and efficiency of that practice and its relation to the cost limitations imposed by the character of the product and its market.

The final design, therefore, is affected by a great many things inside and outside the plant. In all cases the most important part of the problem is the human element. In the matter of materials, tolerances must be met, specifications must be secured with a maximum uniformity so that the labor and time involved in the examination, rejection and replacement shall be reduced to a minimum. Machinery must be kept in accurate condition so that the work can be done within the required allowance within the plant. Inspection must be adequate without imposing too large a burden upon the expense of the business, and the practical changes required by the design must be such as can be made without too large an investment.

This article does not concern itself with the difficulties arising from the human inefficiency outside the plant. It is concerned with the limitations imposed upon the engineer on account of the human inefficiencies existing within the plant and their effect upon the final service of the product as an engineering matter.

Elements of Limitation

The limitations arise out of the following elements:

a—The maximum average accuracy of work.

b—The cost of the supervisory departmentals.

c—The knowledge of practice obtaining within the plant.

d—The original work of research and study which has been done within the plant.

Inasmuch as the first two elements deal with the general labor situation, and, therefore, the large number of individuals within the establishment, it is interesting to observe the limitations which may be imposed upon the designer by the conditions existing in the plant.

During the war, when plants sprang up over night, skilled mechanics were made in a week and men were called to inspection before they had become acquainted with snap gauges, block gauges, micrometers and testing tables; a great deal of material went through and was passed which amazed the man who used it because of its inaccurate operation. This work was not large in proportion considering the conditions, but it was sufficient in volume to represent an enormous cost to the Government and a tremendous loss of time and effort.

The mechanical equipment was all right; the system similar to those systems already adopted; the results did not reach the usual accuracy and were not as good. The fact is that accuracy is a human quality, a matter of mental alertness, care and co-ordinated mental and physical skill.

A great many engineers and manufacturers have been inclined to believe we were eliminating the human error by the accuracy of the mechanical equipment. Sometimes manufacturers of mechanical equipment have explained the perfection of their products by talking about the elimination of the human element.

We have been inclined to minimize the mental alertness and co-ordinated mental and physical skill required in order to produce accurate work from an accurate machine. The decrease of human efficiency in the war was no less observable in the inspection than it was at the bench.

Supervision from an inspection standpoint has increased quite largely as the tolerances have become closer in quantity machine work.

Even with the increased inspection and supervision the amount of rejected work per thousand dollars of product has not grown less and in some cases has grown larger.

Average Accuracy

The designing engineer is necessarily limited in his design work by the average possibility of accuracy and the cost of securing a certain accuracy. In some plants tolerances have been increased on some operations because the cost of securing the original tolerances was too great. It is of little use to insist upon accuracy to certain fine dimensions, plus or minus, if the actual product does not come within the limitations of that accuracy.

The mere fact that the mechanical equipment for such accuracy is provided does not insure its actual production. In fact, it insures very little. In a very large establishment in the automotive field where the system is considered efficient and the product very good, an examination of the inspection department showed that the key blue prints were out of date to a considerable percentage, while the other blue prints used by individual inspectors and foremen were obsolete to a much larger degree. In some of the departments blue prints were hardly used.

In a factory two or three weeks ago, I watched two men grinding small pins and checking their work with a gauge. The actions of the men had become almost automatic. It was evident that their minds were busy on other things a certain percentage of the time and it was equally evident that the work was not going through as accurately as it was supposed to come through.

One of the reasons for the variation in the action of completed machines is the tendency for tolerance errors to accumulate in a certain percentage of cases, while in other machines they do not accumulate.

These differences in accuracy and the increased cost of supervision as the drawings call for closer tolerance, nullify to a certain degree the purpose of the closer opertions and render the designing engineer's work useless to that extent.

We have leaned too much upon the ability of the mechanical device to take the place of human care and skill in dealing with the operation and inspection of the product as it passes through the plant.

Nothing can replace the efficiency of understanding in the manufacturing organization. Where the reason for the accuracy is not visible the object is to secure as much money and to get by with as much product as possible. Where the inspection is operated largely by men to whom the reasons for accuracy are just as obscure, the character of the inspection suffers to the same degree. Addition to the system of inspection does not decrease the error or the amount of rejected work because the individual alertness is not improved and the individual capacity to catch the mistake is not increased.

The engineer, of course, is limited not only by the efficiency of present practice as represented by the average efficiency of the worker, but by the cost of securing that general average through the supervision necessary for its maintenance. It is interesting to note that supervision has increased considerably in factories where the operations have been highly standardized and the number of workers is large. This adds to the total cost of the manufacturing operation and requires the engineer to accept lower standards of design because of the additional cost involved in securing the higher standards of work.

The improvement of practice within the plant depends upon the same human qualities as the maintenance of a high average in its accurate development. The constant elimination of unnecessary detail, the development of system to the point of efficiency without the burden of unnecessary motions, the proper division of responsibility come out of the human spirit within the plant and are not depended wholly upon the mechanical equipment. Constant development and practical improvement enable the engineer to put more service into the product without increasing its cost and in a way affect the character of the design itself.

Of course the value of the design is affected also by the character and quality of the human organization within the engineering department itself. The same difficulties are to be met in the routine work of preparing working drawings that are met in the routine work of turning these drawings into actual product.

The development of the departmentalized system with its centralized control has led to the same difficulty in improving the average accuracy and again the remedy is to be found in the alertness, the coordination of mental and physical skill and understanding, and not in the system of sub-division or centralization which occurs.

In the progress through a number of factories I have been impressed with the fact that the designing engineers are limited more strictly by the human inefficiencies than they have been willing to admit. In all departments from the experimental department to the individual shop, the average accuracy in workmanship is not increasing, the average cost of supervision is increasing and in some plants the product which is turned out does not represent the tolerance and fits that are required on the blue prints. Mechanical equipment can only improve the situation as the human efficiency is considered and taken care of.

Brake Lining Specifications

THE methods used by the passenuger car and motor truck manufacturers for testing serviceability of brake lining vary at the present time so greatly that it is extremely difficult for the brake lining manufacturers to produce linings that will meet the great variety of tests required. Realizing the importance of having some standard method of test generally acceptable to the industry a Brake Lining Subdivsiion of the Parts and Fittings Division of the Society of Automotive Engineers' Standards Committee has been appointed with a personnel consisting of brake lining manufacturers and automobile engineers. A meeting was held recently in New York at which the problems involved were thoroughly discussed.

At this meeting data covering a series of tests which had been run at the Bureau of Standards on a special testing machine recently described in these columns were submitted. It was decided to build several similar testing machines in order that all the members of the Subdivision can run a series of tests with a view to deciding upon a definite specification for testing brake lining after the results of the different tests are compared.

It was the consensus of opinion that any specification adopted should be such that it would not require expensive testing apparatus and that the establishment of a standard specification would be of great value to the passenger car, motor truck and axle manufacturers.

ANNOUNCEMENTS concerning the Engineering Number of AUTOMOTIVE INDUSTRIES indicated that a description of the Ricardo engine would be included. Numerous engine designs attributed to Ricardo are in existence, but we have been unable to secure working drawings of the particular engine using stratified or localized charge which we had in mind, for the reason that this engine was purely an experimental design. A diagramatic sketch showing the principle of operation of this engine, and some results of tests run on the experimental job are given in the lead article of this issue, "Where Are We Getting in Efforts to Solve the Fuel Problem?" We anticipate printing in an early issue a description and test results on the Ricardo supercharging engine, also referred to in the lead article of this issue.

FACTORS AFFECTING DESIGN

Taking Advantage of the Other Man's Knowledge

The design engineer, like other specialists, will do his task best if he takes advantage of the cooperation extended by contributory or related industries. His design is affected by production problems in these outside plants and a greater degree of consultation will be beneficial.

By Norman G. Shidle

SAMUEL JOHNSON never saw an automobile. But he one time made a remark to his follower, Boswell, which should be understood by every automobile designer and engineer. He said, "Knowledge is of two kinds; we know a subject ourselves, or we know where we can find information upon it."

Life is too short to allow a man to be a specialist along many lines. The best he can hope for is to understand one line thoroughly and to have a general knowledge of related lines. Approaching his task with this conception, the automotive design engineer will analyze carefully the sources of information available as regards those factors of production outside his own plant which have a bearing upon the work of designing.

Before the engineer is given the blank sheet of paper upon which to begin his design, he usually has imposed certain general specifications previously determined by the management. It is assumed that there is some purpose behind the building of every new car and every new model. The management will probably have determined from a survey of the market the general type of car and the price class in which it desires to manufacture. Within these limitations, then, the engineer begins to work out his design.

Limitations

But other limitations immediately appear; limitations imposed by the production practice which must bring into material being the car conceived in the mind of the engineer. Part of these production limitations are imposed by the equipment and production possibilities of the automobile plant itself; others by the practice of industries and companies which supply certain parts and materials to the automobile plant. In either case the engineer must take production problems and possibilities into consideration in making his design. The relation between outside production problems and design is important enough to merit careful consideration. In making designs, some engineers, of course, have taken cognizance of the limitations of outside production practice to a greater extent than others, so that some phases of this discussion will not be new to certain designers. But there are probably advantages to be gained from closer attention to these factors in almost every instance.

Sometimes designs, difficult of production, are made unconsciously, because the designer is unfamiliar with the limitations of practice in the industry by which the part must be made. In other cases an intricate design is consciously made to achieve a certain end. In any given instance, of course, it becomes necessary to judge whether the increased production expense of the difficult design is compensated for by its superior qualities from an engineering viewpoint.

Avoiding Difficulties

Conversations with executives in the drop forge, die casting, malleable casting, steel casting, transmission, ignition and similar industries, however, indicate that excessive costs are frequently run up by the necessity of producing intricate designs, which might have been simplified or made according to stock models without changing the inherent nature of the piece. This difficulty probably could have been avoided in many cases had the advice of the related industry been sought at a somewhat earlier stage of the design.

The experience of a die casting concern with a certain brush holder furnishes an excellent example of this. On this brush holder there were two round pins projecting. These pins fitted into two holes in another piece, and the flat plate from which they protruded had to fit flush with another flat surface. Because of this fact, in the original design there were very sharp shoulders where the pins met the flat surface.

Sharp shoulders of this kind cause trouble in die casting because of the danger of cracking when the piece is removed from the die. It was possible to make the piece as originally designed, but the percentage of imperfect pieces would necessarily have been rather large.

Had it been possible to leave a fillet between the pin and the flat surface, the die casting operation would have been simple. This was impossible, however, in this case, since such fillets would have prevented the flat surface fitting flush with the other flat surface in assembling. The die casting engineer finally changed the design by recessing the flat surface at the base of the pins and allowing for fillets in the recesses. In this way the die casting operation was made possible and the assembly necessities provided for as well.

Co-operation in this case enabled the customer not only to reduce his costs, but also to get a satisfactory and uniformly sound product day in and day out.

Any increased cost added to a car or truck becomes a serious matter at this time. The designer can profitably consider the possibilities for increased co-operation with related industries and the benefits which such co-operation may give. He must examine, at the same time, the limitations which bound the extent of such co-operative effort. The necessity for consultation will vary with each engineer in inverse proportion to his previous knowledge of the methods and practice of related industries. But every engineer can gain something from an attempt to utilize more fully the facilities offered by the various outside firms.

Standard Parts

This situation applies not only in relation to forgers and casters, but also in the contact between the engineer and the parts maker. Even the engineer, whose designing consists chiefly of collecting standard parts for assembly, is confronted with the same difficulties to some extent. A small change in a transmission part, a front axle or differential may give the assembled car a certain individuality in the eyes of the engineer, but may increase the total car cost without adding anything of real value from the consumers' standpoint.

A case in point occurred recently in connection with a certain shaft of a standard parts unit. The particular designing engineer desired to have one-sixteenth of an inch more machined from his shaft than was customary in producing the part in very large quantities for many other firms. The parts maker is authority for the statement that the extra machining accomplished no special purpose, as the weight factor involved was so minute as to be of no importance.

To meet the requirements of this engineer the parts maker had to retool a large number of machines and readjust his facilities to make the change. The increased cost was great and naturally added to the final selling price of the car.

This incident occurred during the time of peak demand for cars. It was not good practice then. At the present time several such incidents in connection with a single car might have serious results.

Time for Consultation

At what stage in the making of the design should the first contact be made between the engineer and, for example, the related industry? The case of a drop forger may be taken as an example. The drop forger is likely to feel that the contact is not made soon enough in a majority of cases. He has experienced difficulty many times when a design has been brought to him fully completed. He has been expected to produce a forging at a reasonable cost, even though some small feature of the design renders the forging process very difficult and expensive. A slight change in design might simplify the forging process immensely. But perhaps such a change at this stage of the design would necessitate other changes in other parts with which the part under discussion fitted.

Consequently, there is nothing to be done at this time except produce the difficult forging at a high cost, or change the design of other parts at a corresponding engineering expense. Neither alternative is thoroughly satisfactory to the automobile company, and friction with the drop forger often results.

The related industry engineer is likely to feel, as well, that he is not sufficiently taken into the confidence of the designer as regards the full design. To give the best service on the part which he is to make, he needs to know the details concerning the parts to which it is to fit in the finished design, and the other factors involved in any slight change which might be desirable on the particular piece. He often gives the best advice and assistance within his power on the basis of the data available, but sometimes feels that he is blamed for not giving better advice when he has really been asked to judge on the basis of insufficient data.

Designing New Parts

This is especially true in the case of new parts which have been made by the particular related industry only to a limited extent. As die casting has developed, for instance, the industry has been able each year to make parts which had never before been possible. The designing engineer, while he may understand die casting in general, is likely to fail to consider some small point in practice which seriously affects his finished piece, unless he gives the die caster full information.

One firm recently sent for die casting a dashboard gasoline gage. The drawing was given to the die casting concern; samples were asked for; but the designer failed to indicate what parts of this piece had to fit with other pieces in assembly; what parts had to be made to extremely close limits and on what parts a little leeway could be allowed. Here is what happened.

In die casting, ejector pins are necessary to eject the piece from the die after casting. These pins leave a small mark on the metal. The die caster always places these ejector pins in such a way that the mark will be left in a place that is not exposed or in a place where they can be removed without affecting the tolerances allowed.

The dies for this job were made up and the sample castings made. Then it transpired that the ejector pins had been placed on the only surface of the whole piece which was of any importance from the standpoint of having to fit accurately with another piece. Consequently, the dies had to be changed and the work was delayed. In this case the die caster stood the expense of the change, but this cannot always be expected. The difficulty would never have arisen had the die caster been given full information upon which to base his work.

To illustrate the kind of information necessary to the related industry plant, if it is to render intelligent and efficient service to the automotive engineer, the following list of questions is of interest. This list indicates the data which one large die casting firm considers essential when taking an order for a piece. The purpose of the questions is not to satisfy curiosity, but to give the die casting firm the data necessary to intelligent service. While the relative importance of the various items would be different in the case of forgings or castings of other kinds, and, in the case of unit parts makers, the necessity for full information along the lines indicated is present in any case. The list is as follows:

1. What kind of surface finish will part receive when finished?
2. What or where are important dimensions to be maintained?
3. Where is trade mark and part number to be located?
4. If machined, where is locating point?
5. Method of inspection?
6. Does it assemble with other parts?
7. Under what conditions is part to be used?
8. Accuracy required?
9. What metal shall be used?
10. Can we change design?
11. Present method of manufacture?
12. How will our castings be finished?

Some engineers have less trouble than others, but certain difficulties are sufficiently common to warrant

serious discussion. The executives in the related industries claim to have built up extensive engineering service facilities to aid the automobile engineer in the solution of his problems. These departments are capable of and ready to co-operate fully with the designer. The designer will benefit by their services in accordance with his desire for assistance and the extent to which he will take the related industries into his entire confidence.

The Designer's Side

Then there is the designer's side of the case. He naturally approaches his task with something of an artistic as well as a scientific viewpoint. He may desire to make his design not only satisfactory from a utility point of view, but also possessed of a certain individuality. He is not always content to sacrifice this individuality to the easiest production methods.

Economy of production is especially desirable, however, in all cases, other things being equal. The designer should consider very carefully before sacrificing economy to individuality, particularly where the part in question is not visible in the finished product.

One engineer, for instance, objected recently when a castings manufacturer was consulted about design details. The foundryman thought only of modifying the design in such a way as to make it easiest to cast. He failed to consider the engineer's viewpoint sufficiently. These two men needed a fuller consideration of each other's problems.

Moreover, the assistance given engineers by related industries has not always been rendered in a broad, unselfish manner. Some designers have found certain companies in related industries which would recommend changes in design to fit the part for production by the equipment of this particular company, when there was nothing inherent in the practice of the industry which would make production of the piece especially difficult. In other words, the advice was given with the purpose of modifying the design so that the particular company would be able to handle the order, even though it were not equipped to handle all classes of work in the most efficient manner possible.

The possibility of this factor entering has undoubtedly been one important cause of the engineer's reticence when discussing design with related industries. The degree to which this suspicion is justified varies with individual cases, but it has led many engineers to take the attitude of "Here is the design; now how much do you want for making the piece?" In brief, the presence of this factor has been largely responsible for what lack of co-operation still exists.

Making a Survey

When there is time a survey can be made. The engineer can consult with a number of firms, any one of which might get the final order. He can get some information from each one, can weigh that information in bulk and, by studying the results of his survey, determine rather accurately what are the real facts in the particular case.

The engineer might learn something from a skillful purchasing agent along this line. A purchasing agent for a big firm is rarely trained in the technical phases of the materials which he has to buy. But he listens carefully to the stories of the various salesmen who come to him; he draws from each of them what information he can; he learns something new every day. And after a while he is thoroughly capable of judging the relative merits of articles, the fairness of a price, or the production possibilities in any given case.

The purchasing agent is a student of human nature and a big user of common sense. The engineer can use his methods to advantage.

The engineer can consider how far it is possible to eliminate disturbing factors, overcome the intervening difficulties and gain the decided benefits which accrue from increased co-operation.

Co-operation Essential

The attitude, honesty and breadth of business vision of the particular firms involved will probably decide the possibilities for full co-operation in any given instance. An extensive survey of the situation, however, indicates that the progressive firms among the related industries have definitely come to a realization of the necessity for broad and honest service on their part when giving advice or rendering aid through consultation. Many of them have built up extensive research departments to anticipate the requirements of their customers, and are fully equipped to do any job that is within the scientific limits of the practice of their industry.

The trend toward better co-operation is voiced by one drop forge executive, who says: "The general trend among automotive engineers is to work more closely with the drop forge industry in designing important parts, so that difficulties can be eliminated and the best part for the lowest cost be produced." And by the die casting producer who said recently that "when we can make suggestions leading to a reduction in cost of the piece it is to our advantage, since our percentage of profit is the same in any case and the reduced cost means a satisfied customer." A general survey of the field indicates that the views expressed by these men are typical, and that the importance of intelligent cooperation is being more fully recognized.

Practically all of the progressive concerns in these contributory industries have recognized the truth stated by the die casters, and engineers can undoubtedly reduce costs and save effort by taking advantage to the fullest extent of the services which these firms are ready to render; by co-operating more closely with them in the early stages of design, and by recognizing fully the vital relation between the design and the production problems outside the automobile plant.

Magnet Steel of High Retentivity

AN alloy steel, remarkable for its high coercive force and strong residual magnetism, was discovered by K. Honda and H. Takagi in 1917, and was named "K.S." steel after Baron K. Sumitomo, who had made a liberal donation to the inventors' university. The steel, since improved, was first described by Honda and S. Saitô in the "Physical Review" of December last. The composition is in per cent, carbon 0.4 to 0.8, cobalt, 30 to 40, tungsten 5 to 9, chromium 1.5 to 3. The alloy is brittle, and the forging of it requires practice; it is best quenched at 950 deg. C. in oil, and requires no heat treatment when used for permanent magnets. The coercive force is up to three times as large as that of the best tungsten steel, whose residual magnetism it also surpasses. Prolonged heating in boiling water did not diminish the residual magnetism of the K.S. steel. The hysteresis loop has a very large area. By quenching the annealed steel, the Brinell hardness was raised from 444 to 652 and the Shore hardness from 38 to 55; the microstructure of the quenched, very hard steel is very fine. When specimens were dropped on a concrete floor from a height of 1 mile, the magnetization diminished only by 6 per cent. The K.S. steel is suited for short magnets.

FACTORS AFFECTING DESIGN

Some Production Problems Which Influence Design

Co-operation between the design and production departments is essential for economy, but design from the production standpoint only may result in unsatisfactory performance or excessive cost in service operations. Some items of design tending to facilitate production are enumerated.

By Herbert Chase

A LONG interval of development has occurred between the time when the artisan was usually the designer of the product which he produced with his own hands and the present day, when the machinist often knows little or nothing about the design of the intricate device on some part of which he performs one or two simple operations, often with the tools themselves guided so that all he must do is to clamp the piece in the machine. The mechanic is no longer a designer, but to be a good designer the engineer must know, at least in a general way, how machines and their operators will best be able to produce the parts for the mechanism he designs. He must know also what materials are suited for use in the piece, not only to give it proper strength, but to suit it to ready machining and heat treatment, if this be desirable, and to render it easy of assembly. These, of course, are not the only limitations upon design, but they are important and, of course, are increasingly important when quantity production is involved.

Conditions which govern the relation between the designing or the engineering and the production departments in different plants vary greatly, but are often determined by business policy and, so far as the automotive industry is concerned, plants may be roughly classified as follows:

(A) Plants in which the aim is to make the best possible product, without pecuniary consideration to cost. In such plants the final decision in the design usually rests with the engineering department, subject, of course, to review by the executive.

(B) Plants in which, within certain limits, lowest possible cost of production is the first consideration. In such plants the design is usually governed largely by the views of the production department, and the design may even be laid down by an engineer who is primarily a production man.

(C) Plants in which price limits are necessarily set, but in which certain leeway is allowed the engineering department so long as these limits are not exceeded. In such plants the engineering and production departments are substantially on a par and of necessity work in close harmony.

(D) Plants which merely assemble standard units. In such plants the engineering policy is determined largely by the purchasing department, which is apt to be guided more by the cost of the units available and their effect upon salability of the assembled product than upon engineering considerations, so long, of course, as the units will go together and perform with reasonable satisfaction.

In the case of plants in classes A and C, the original design is prepared by the engineering department after conference in which the executives and sales departments determine, in a general way, type and size of vehicle or part that will meet marketing conditions. Even these preliminary selections may involve an engineering investigation before an intelligent selection of type is possible. The original design will naturally be such as to facilitate production if the engineer knows production methods, but will not sacrifice engineering merit to a marked degree in order simply to make production easier, so long as the unit or machine is not too difficult of manufacture.

Plants in class B are of necessity controlled largely by the production department. Much money may be spent in perfecting the original design, which, when new, may compare favorably from an engineering standpoint with other up-to-date cars or parts in about the same class, but will be designed to minimize production costs. When once in production, however, changes in design become so expensive and affect service and other departments to such an extent that the tendency is to postpone the change until competition or some other factor compels it. Tooling costs are so great and changes in factory layout and routine so expensive that changes in design become well-nigh prohibitive, hence the functions of the engineering department, so far as design is concerned, are decidedly limited.

Since plants in class D are almost wholly dependent upon outside production facilities, changes in design are relatively easy of accomplishment, providing the producer of the parts or units involved are offering the desired equipment, while in any case the assembler is little affected.

From the foregoing it will be apparent that the effect upon production of design is quite different in various classes of plants, and it is probably quite as true that similar designs affect different plants in the same class in much different ways, for the organization, product and equipment are not the same in any two plants. For these reasons it is impossible to lay down any hard-and-fast rules governing the effect of design upon production problems, but certain rather general observations and

some concrete illustrations will perhaps serve to throw some light on the subject in hand, though there may be little that is new in what is said.

The designer can gain much useful information by acquainting himself fully with the production methods and facilities which the plant or plants which will be called upon to produce the parts for the assembly he is to design. There is a great difference in the facility of production as between pieces performing the same purpose but produced in different ways, and the designer who does not know or appreciate the difference in method labors under a handicap himself and, to a certain extent, places his company at a disadvantage in respect to competitors. Again, a piece which is easily produced in one shop with certain facilities may involve very difficult production problems to a shop differently equipped, yet by certain more or less non-essential changes in the design the second shop may be enabled to produce a piece performing the same function with equal efficacy and thus utilize equipment which would otherwise be idle.

It may seem more or less trite to suggest that closer co-operation between the design and production department is desirable, yet it is not an uncommon thing for the engineering department to belittle the suggestions and problems of the production department, when a little time and effort spent in examining the conditions which the latter department has to contend with would convince the engineer of the desirability of the change. On the other hand, the production department must not overlook the fact that other factors beside ease of production should be considered in the design. As a rule, the production department sees but little of its product after it leaves the plant and is apt to think of it largely from the viewpoint of facility in manufacture and assembly, and perhaps without due regard to serviceability or ease of dismantling in the repair shop. As an example along this line we have in mind a certain assembly of gears used in a rear axle. The design placed in production involved pressing one of the gears on its shaft after the gear was in place in the housing, for the opening in the housing for the shaft was not large enough to pass the gear. This made an awkward assembly and a difficult one to dismantle. It was, therefore, suggested that an opening of sufficient size to pass the gear be provided in the shaft axis, and the cover plate be arranged to carry the bearing. This was done, with the result the assembly of gears and shaft was facilitated and done independent of the housing, and dismantling was rendered unusually easy.

In another instance the production department suggested a change in the design of a truck hub with the intention of facilitating its production, this change involving extension of the hub, lengthening of the live axle and a change in the external surface of the hub such as to destroy the flat, conical shape. There was no doubt as to the advantage of the change from the production standpoint, but it would have increased the overall width of the truck and have rendered the axle much more liable to injury, since the conical shape tended to cause a blow to glance off. Thus the change would have increased liability to injury and helped to increase sales resistance by destroying a feature of real merit. The change was not made, but would probably have been made had the production department controlled the situation.

The ideal system is one in which the designers and the production men, as well as the sales and service departments, co-operate from the very start in preparing the design. This is well illustrated in the case of a certain manufacturer who had been purchasing a stock transmission from a parts maker, but for certain reasons had decided to build his own transmission unit. The engineer did not proceed with the new design before conferring with other department heads, but called a conference at which the engineering, production, service, sales, purchasing and advertising departments were represented. Among others, there were present men who specialized in the production of gears, in pattern making and foundry practice, in assembly of units and of the chassis frame units, in machining and heat treating, in repair, etc. Laid out on tables were the parts of the gearbox then in use and of other competing makes of gearboxes. All present were given an opportunity to examine these parts and then to express an opinion as to the general type of construction and features of design which they felt should be incorporated. At the direction of the chief engineer, who presided, a draftsman and stenographer made notes of the suggestions advanced. As a result of this conference a preliminary design was laid down incorporating, so far as possible, the suggestions made, and a second conference was called to criticise this design. As a result, several changes were made, and some experimental transmissions were then built. Following tests of these and the experience gained in the shop by making the samples, some further changes were made before quantity production started, but the final product was highly satisfactory from every standpoint. Furthermore, since all departments at interest were consulted, all were themselves sold on the job and knew its merits. This was an advantage, not only to the production, engineering and service departments, but to the sales and advertising departments, which more fully appreciated the merits and limitations of the design, but to the purchasing department, which better understood the reason why certain materials must be had to produce the desired result.

The foregoing procedure is not always necessary or desirable, but might with advantage be followed in more cases than at present. The procedure in some large production plants, in the case of a new design, is first to decide upon the general type and price of vehicle or unit to be produced, second to give the engineering department a free hand in laying down the design, so long as the foregoing limits are not exceeded, and third to depend upon co-operation between the engineering and production departments for such alterations as may seem to be desirable from the production standpoint to facilitate manufacture. If, as sometimes happens, the production department has the final decision, perhaps, in spite of sound engineering objection on the part of the designer, trouble which is expensive to remedy may result. Other instances in which the sales department has been successful in over-ruling the better judgment of the engineering department with disastrous results can be recalled, but from this it should not be concluded that the engineering department is infallible, for it, too, makes mistakes and is not always unprejudiced—in fact, is sometimes much too arbitrary in its decisions.

The diversity in policy and methods referred to above, as well as differences in organization, make it impossible, as indicated heretofore, to lay down hard-and-fast rules to govern the design as affecting production, but some general observations to which there will be many exceptions may not be amiss.

1. Machined faces on castings, such as cylinder blocks, for example, are produced most readily when these faces are parallel or at right angles and in as few planes as possible.

2. Drilling and tapping operations are often facilitated when the axes of the holes are parallel and at right angles to a machined face opposite the joints of entry of the drills.

(*Continued on page* 1313)

FACTORS AFFECTING DESIGN

A New Method of Automobile Body Suspension

New idea in body suspension is put forth here by Mr. Mercer. There are two supports on each side for connecting the body to the frame and the body sills are outside the frame. The design presents a new idea.

By George J. Mercer

CONSIDERABLE criticism has been directed against body work recently because of the lack of durability of many jobs. The body engineers, however, appear to be having their day in court and are attempting to justify the results of their work. Their defense is chiefly concentrated on the fact that bodies are subjected to excessive strains as they are now carried on the chassis. They claim that the body is bound to show early deterioration because it is thrown, bumped, twisted, and distorted all out of proportion to its ability to withstand such strains, and that limitations of weight and chassis construction usually prevent body construction sufficiently strong to stand up under such treatment.

The body really is called upon to withstand greater strains and harder usage than any other part of the car, considering the limitations under which it is built. A body can readily be made to hold together and to perform properly if it is made sufficiently strong. Such construction, however, means added weight, since the frame must be heavier than usual, heavier gage metal and additional braces must be used.

To do this is not feasible since the ideal body, from a practical standpoint, is that which is built as light as possible, but sufficiently strong to stand up.

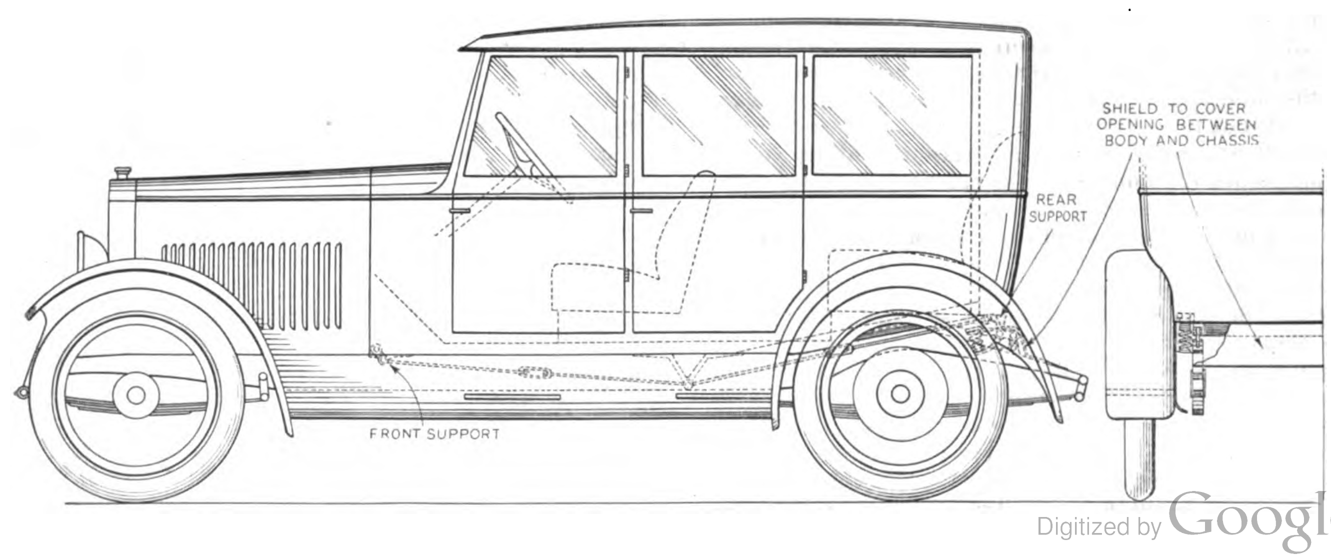
As a result of these necessities the average body is virtually a shell or casing. It is not even a completely self-bracing structure, because the cutouts for windows and doors limit the ability of one part to brace another.

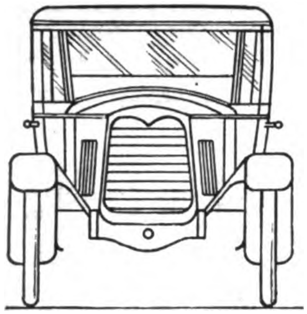
Real progress has been made, however, in the construction of both open and closed body types. Reduction in the variety of body types produced has been a material help in this progress, since the builder can concentrate his efforts for improvement without a greatly increased expenditure. Past experience has shown where the strains are greatest, while the improved quality of steel has aided development materially as well. Steel can be so easily worked now that it has supplanted aluminum in many cases. It can also be welded in such a way that the joints are as strong as the rest of the sheet. Thus the whole outer panel can be joined, although there are certain points at which it is better to allow the body to work out the strains. By joining the outer panel in this manner a compact self-supporting exterior is produced which materially lengthens the life of the body.

It is conceded that the bodies of the future will be made lighter and stronger than those of the past. This increased strength will probably be obtained through the use of interior bracing, which will make all parts support the strains instead of having the strains localized as is usually the case at present. Combination wood and steel bodies will continue to be made for a long time to come, because such bodies make for ease of manufacture and low initial production costs. It costs more to start in all-metal production, yet this type has its advantages.

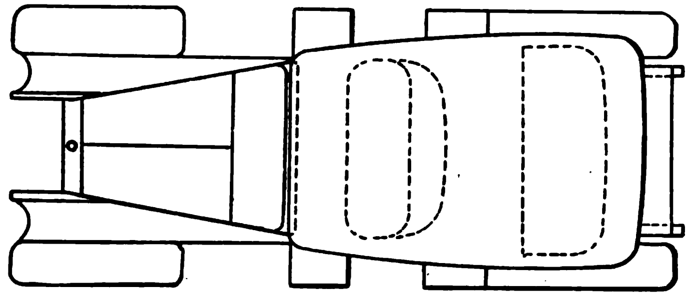
The combination body, however, can be made lighter than the all-metal body, and lends itself better to present manufacturing methods.

The all-metal body presents certain advantages in connection with finishing not given by the combination type. Enameling or baking processes can be used instead of

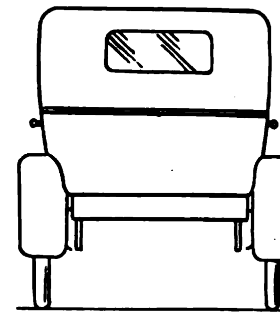




FRONT VIEW



TOP VIEW



REAR VIEW

painting. Such processes give a more durable finish to the body surface and can be applied in about one-tenth the time and space required for regular painting. These methods are possible also, however, with the combination body in some cases. The writer has built a combination body on which the panels were enameled and believes that this will be the general practice of the future.

These statements are made, not because the writer is preparing to demonstrate any theories, but simply to present one of the methods which he believes will become more common as time goes on and to help establish its relative value in solving the chief body engineering problem that exists to-day—body deterioration.

New Body Suspension Method

It is possible, however, to compensate for excessive chassis distortion by a method of body suspension different from that now in general use. The accompanying illustrations show theoretically this entirely new idea. The plan has been worked out by the writer on paper only, for the purpose of illustrating publicly a theory which may at least bring out a useful thought. Before any solution of the difficulties of body panels breaking and coming apart at the joints, doors jamming, roofs squeaking, etc., can be found, the method of assembling the body on the frame must be taken into consideration and used as the starting point for the investigation.

It is not necessary at this time to prove that the body is subject to distortion and jolts because of the constant weave of the frame when the car is in motion. This fact is common knowledge. An open car can absorb a great deal of these strains, because it is less rigid than the closed car. Therefore the weave does not appreciably shorten the life of the body, provided the body can weave in unison with the frame and provided the weave can be absorbed at points where the panels meet but are not welded.

The closed body with a permanent roof is rigid. The jolts are like hammer blows administered directly on the body. The accompanying illustration shows one method of supporting the body semi-independent of the chassis and thus augmenting the power of the rear springs to absorb the shocks.

In working out this new idea, the writer intended that the appearance of the car should not be materially different than that of the ordinary car when completed, and that any devices added should not appear grotesque. The illustrations showing the side view of the completed car, together with a miniature of the front, back and top, will indicate the degree to which he has accomplished his purpose.

The side view has been utilized to show the new method of suspension, as has the section of the rear view. The two sectional views show in larger size the detail of the support.

Looking first at the side view, it will be noted that there are two supports on each side for connecting the body to the frame. The supports are indicated on the drawing. The front support is near the dash and is simply a pin or socket. The pin is fastened to the frame and the socket to the body, so that the body can move up and down at the rear, rotating on the pin support at the front.

The chief point is that the body sills are outside the frame, with sufficient clearance to allow the chassis frame to move freely up and down within the space allotted, without touching body sills or floorboards. As the body will be supported only at the ends, the weight of the body must be supported between these extremes. A truss with two turnbuckles provides this support. The truss rod is anchored to the irons that form the supports and the body frame, therefore, is an entirely self-supported unit. The truss is outside the chassis frame and is hidden by the splasher forward of the rear mudguard.

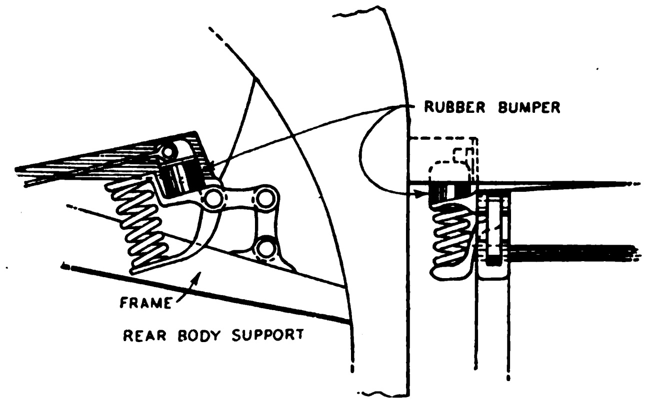
Assembly Advantages

The splasher is of the type chiefly used on roadsters and touring models. Steps are used in place of runboards to simplify the assembling of the body to the chassis. This assembly can be accomplished simply by making connection at the four points. The splashers and rear mudguards can be put on the body before the body is set on the frame of the car. Thus the inconvenience of assembling the rear guards to the body after the body is mounted is avoided. The whole body, splashers, and rear guards can be raised above the frame and lowered until the pins can be slipped into place. Then the front guards can be connected to the splasher and the car is complete. During the entire operation the truss is accessible for the purpose of adjusting the door openings.

The enlarged side view shows the body supported on an arm that in turn is supported at the rear to a movable linkage to the frame. At the front it rests on a spiral spring, that in turn is supported at the bottom from the body. Opposite the spring at the top is a rubber bumper. When the chassis is forced or thrown quickly upward, the movement instead of being transmitted to the body as a shock will communicate its force to the end of the arm supporting the body at the point where it it attached. This will throw the forward end of the arm down at the front against the spring, and as the spring action is quickly responsive, the result will be that the upward throw of the chassis frame will simply register on the spring, and the body being supported at the center of the arm movement, remains fairly stationary during a vigorous oscillating action of the chassis.

The principal function of this compensating device is to provide for the upward thrust of the frame. When riding level there will be no action different than with the average car. When the one side of the car drops into a deep hole, naturally the side of the body will follow, because it is tied together. The rubber bumper will help a trifle, however, and the action will certainly be easier than when the body is bolted tight to the frame. But as stated before, the device is primarily to absorb the sudden

up jolts, by permitting the frame to rise without taking the body with it. And since the action is one way, there will not be an added oscillation to the body when conditions are normal.



The Cost Phase

In determining the practicability of any new design, the question of cost is always important. It is fair that the design should be examined from the cost as well as the engineering standpoint. Viewing this new idea from the cost angle, several definite points appear. The chief factor in the new design tending to increase cost is the expense of truss and forgings at back and front. These parts must be real safety appliances. Steel castings would probably be the best material for combining the requisite strength with reasonable cheapness.

Several points in regard to the production, however, tend to offset the increased cost mentioned. These may be listed as follows:

1. Saving in mounting body on frame. Guards and splashers can be put on before body is mounted.
2. Saving of time, labor, and material in putting on neversqueak material and bolts.
3. Saving of trouble which often occurs when bolts pull body out of true and doors will not work. In such cases the bolts have to be loosened, the body shimmed up, and tried out for door clearance.
4. Greater ease in riding in rear seat increases the life of body, because body does not register all road bumps.

A fair comparison of costs, considering as factors the increased life of the body and the elimination of many customers' kicks, will show that the first cost of adding this or some similar device will not be prohibitive in any sense. Moreover, this initial cost will be so nearly balanced by the cost of the parts displaced and the time saved that cost will not be a factor in determining its adoption, once its effectiveness has been demonstrated.

The tentative plan suggested is not to be confused with something that has been tried out and tested. It cannot be referred to, therefore, as something that definitely will alleviate the problem that has brought the idea to the writer.

This design is set forward merely as the outcome of thought expended in trying to find some way of improving the form of body suspension in use. The idea of having the body suspended and of allowing a semi-swinging motion for body play is based on the idea in use on old carriage construction. There the body was suspended from straps. Cumbersome as this form of suspension appears, it made a wonderfully easy riding coach, and the adoption of steel springs seldom if ever were as easy for the passenger as the straps that they superseded. Therefore with this idea in mind as the basis for a plan, the writer has approached the subject with the result above illustrated. The idea is presented with the purpose of starting on the first lap of investigation designed to clean up mooted body questions that have remained too long in the background, simply because other matters more vital to the life of the car had to be settled first. Too often those in charge of the body department in car factories are not practical men in the sense of having had body experience. This is so because the bodies are more often than not made outside the factory by contractors and the factory body man is frequently an executive who arranges for the quantity and price, relying on the contractor for the practical part of the work. Under this plan, the factory representative is really a production man rather than an engineer. Therefore it has taken time to arrive at the stage of putting the spotlight on body troubles and treating them from an engineering point of view and of trying to eliminate the difficulties at the source.

German Car Prices Rise

INCREASES ranging from 125 to 130 per cent were made in the prices of passenger automobiles in 1920 in Germany. According to information furnished by the Deutsche Automobilhaendlerverband (German Association of Automobile Dealers) of Berlin, and forwarded to the Bureau of Foreign and Domestic Commerce by Howard W. Adams, Berlin, American representative of the Department of Commerce, the prices, in marks, of automobiles in Germany for 1920 were as follows:

	5 Horsepower	10 Horsepower	16 Horsepower
Jan. 10..	18,000	32,000	41,000
Feb. 11..	31,500	56,000	71,750
May 1 ..	39,375	70,000	89,687
June 11.	40,000	75,000	95,000
Sept. 3 .	37,500	70,000	89,000
Dec. 21 .	40,000	77,000	92,000

The figures in the foregoing table represent the minimum domestic prices as furnished the Federal Department of Export Control in application for export permits. These prices apply to new passenger automobiles of average grade. The finer grade passenger automobiles commanded prices relatively higher than those indicated.

The 1920 prices for motor trucks also showed sharp increases, practically the same as those for passenger cars, but not so great from a percentage basis because of the higher bases applying at the first of the year. Prices of motor trucks were as follows, there being a drop beginning in September:

	2-ton	3-ton	4-ton
Jan. 10	60,000	70,000	75,000
Feb. 4	80,000	88,000	93,000
May 1	120,000	130,000	140,000
June 11	120,000	130,000	140,000
Sept. 3	102,000	112,000	122,000
Dec. 21	102,000	112,000	122,000

There was a much greater fluctuation in the prices of used cars, both passenger and trucks, during 1920. The heavy increases in the prices of passenger automobiles was not so much the result of the generally enhanced cost of labor and materials as it was the effect of the new tax on turnover of Dec. 24, 1919, which went into effect on Jan. 1, 1920. This measure carries with it a tax of 15 per cent upon certain articles of luxury, including passenger automobiles.

Problems and Possibilities of the Aluminum Piston

The aluminum piston has been rather widely adopted both in America and England for automobile work. It played an important part in airplane engine development. Its various advantages and limitations are discussed here in detail by an eminent authority on this subject.

By Dr. Walter Rosenhain, F.R.S.

THAT the aluminum piston played a very important part in the development of the airplane engine during the war is an undoubted fact. Whether it will attain—or retain—an equally important place in automobile engines remains for the future to prove, but it is undoubtedly being widely adopted both in England and America. That there are very wide differences between the airplane engine and the automobile engine is, of course, fully recognized, and the question arises whether these differences seriously affect the value of the aluminum piston for the latter purpose. We can form some opinion upon that question by considering the various factors which determine the utility of the light alloy piston in all types of engine.

At first sight, the value of a piston made of a light alloy of aluminum would appear to reside in this very fact of lightness; a saving of weight in any part of an engine, whether for service in the air or on the road, would seem to be valuable, and particularly so in a fast moving, reciprocating part. Yet in aero engine practice, saving of weight by the use of light alloy pistons has always been a minor consideration. Actually, the alloys used have always been regarded as very considerably weaker than cast iron, and the sections of the piston castings as used for cast iron have always been considerably increased when that material has been replaced by an aluminum alloy, with the result that the aluminum piston has often been quite as heavy as the iron one which it has replaced. Thus one possible advantage of the aluminum alloy piston has been deliberately sacrificed, and in the case of the modern alloys, which attain a strength quite comparable with that of cast iron even at the working temperature of the piston, such a sacrifice has been very largely unnecessary from the point of view of strength and stiffness. It has, however, had a countervailing advantage from a point of view next to be discussed.

Heat Conductivity, Not Weight, the Prime Advantage

The real advantage to be derived from the use of an aluminum alloy piston undoubtedly resides in the fact that these alloys possess a very much higher power of conducting heat than cast iron. If such units are chosen that the thermal conductivity of cast iron stands at 11, that of pure aluminum is 52, while most of the alloys which have been used for pistons have a thermal conductivity in the neighborhood of 40, or nearly four times that of cast iron or steel. A piston having a given cross sectional area in those parts which serve to conduct away the heat will therefore carry away approximately four times as much heat if made of an aluminum alloy than if made of iron. Further, if the section of the piston is increased so as to bring the weight approximately up to that of an iron one, this capacity for conducting away heat may be further multiplied by 2 or 2.5. This power of increased cooling of the combustion space has proved extremely valuable in the aeroplane engine. There the power output of a unit of given weight was limited, in one direction, by the amount of compression to which the explosive mixture in the cylinder could be exposed before ignition. This admissible compression ratio depends upon the temperature which the compressed gases attain, since too high a temperature leads to preignition. Thanks to the cooling effect of the aluminum alloy pistons, it became possible to increase the compression ratios of the engines without risk of preignition, thus producing a very marked increase in power, running in some cases up to something like 20 per cent and at the same time effecting a decrease in fuel consumption per horsepower hour. The actual difference in temperature which gave rise to these results has been estimated in various ways—since direct measurement of the temperature of the head of a working piston is by no means easy. Two estimates obtained in very different ways, however, both lead to a similar figure,—viz., that the head of an aluminum piston of good design never rises much above a temperature of 450 deg. Cent., while in a cast iron piston in the same type of engine temperatures of 450 deg. Cent. may be exceeded.

Advantages and Disadvantages of Aluminum Pistons

In the airplane engine, where the highest possible efficiency, not only in regard to fuel consumption, but more especially in power output per unit of weight, is of supreme importance, there could be no doubt of the very great value of the advantages to be gained by the use of the light alloy piston. For the automobile engine, however, conditions are distinctly different and other factors enter largely into the problem. Yet here, too, engine efficiency both in regard to weight and to fuel consumption is of considerable importance, and is likely to be increasingly so in the future. There is, further, the undoubted fact that it is better for an engine in every way if the temperature of the combustion head can be kept down. This is particularly so in the case of air cooled engines, but even when there is water cooling, such matters as lubrication and others are favorably affected by keeping down the temperature. The aluminum alloy piston, therefore, has a certain definite advantage even in the automobile engine, and the only question which can affect its widespread adoption is whether the disadvantages which may attach to it outweigh the gain. This is, necessarily,

a matter for the individual judgment of each designer and one upon which actual service experience must be consulted before final judgment can be given. All that can be done here is to state briefly some of the factors of the problem.

Probably the most serious disadvantage of the aluminum alloys from the point of view of their use as pistons is their relatively high coefficient of thermal expansion. The various alloys which have been used or advocated for pistons do not differ very much from one another in this respect, the coefficient of expansion lying in all of them in the neighborhood of 0.000023 per deg. Cent., as compared with 0.000010 for iron or steel. The aluminum piston, for a given rise in temperature, will therefore expand about two and a half times as much as one made of iron, but—it must be remembered—under similar working conditions, the light alloy piston will not get nearly so hot. If we accept the maximum working temperatures mentioned above—250 deg. Cent. and 450 deg. Cent.—it will be seen that the actual expansion of the hottest parts of the two pistons will not be very different—the expansion of the aluminum alloy piston head being, perhaps, 50 per cent greater than that of the iron one. In view of the fact that these expansions are themselves extremely small, this difference does not amount to very much. It does, of course, demand a slightly greater clearance allowance between piston and cylinder when cold, and this is sometimes objected to on the ground of causing "piston slap" when the engine is started from cold. Even this, however, can be very considerably reduced by a device which takes account of the fact that the lower or "skirt" end of the piston is always very much cooler than the head when the engine is working. It is, therefore, possible to make the initial clearance (when cold) between the piston and cylinder distinctly smaller at the skirt end of the piston. This closer fit of the piston skirt tends to prevent "slap" to a very considerable extent.

Heat Treatment for Aluminum Pistons

It may be objected at this point that in practice it has been found necessary to allow much larger initial clearances with aluminum pistons as compared with those made of iron or steel than the above remarks would suggest. This kind of experience, however, is really the result of employing aluminum alloy castings for pistons without proper previous treatment. Such thin walled hollow castings of light alloys, owing to their high shrinkage and high thermal expansion, are often very considerably stressed internally when taken from the mold. Even during machining they sometimes show signs of slight distortion when the outer layers are removed. When a casting in this condition is put into an engine and exposed to heat and vibration, there is a great tendency for a further release of stress to occur, with resulting distortion of the piston. This is not to be confused with what is often spoken of as "growth" of such castings; here there is no real growth at all, but merely a slight change of shape resulting from the release of internal stresses. Yet such slight distortion, perhaps rendering the piston slightly oval instead of circular in section, will make the piston much too tight in the cylinder unless excessive initial clearance has been allowed. Fortunately, there is a simple remedy for this difficulty: If the castings, before being machined, are "annealed" by simply heating them up to a temperature a little above 400 deg. Cent. (but not above 450 deg. Cent.), followed by moderately slow cooling, then such subsequent distortion cannot occur and much smaller clearances can be safely employed. This preliminary annealing or baking also takes care of the very small amount of real "growth" which may occur in some of the alloys. Only where the alloy has been previously hardened by heat treatment does it become undesirable to employ so high a "baking" temperature as that suggested above. In that case a baking or "tempering" for several hours at 250 deg. Cent. is advisable and satisfactory.

The next point to be considered in regard to the use of aluminum alloys for pistons is their strength, particularly when hot. The very fact that such pistons have been successfully used in aero engines during the war serves to prove that their strength under working conditions is sufficient for the purpose. None the less, it is interesting to examine the question of strength rather more closely, since it has been suggested above that, with the best of the alloys now available, the strength at the working temperature is so good that the pistons could safely be made much lighter than is the present practice. When we look at the records of strength tests made on various piston alloys, particularly at high temperatures, it is surprising that such material should have stood up as well as it has done to the exacting conditions of piston service in a high speed, high duty aeronautical engine.

Alloys Used for Piston Castings

A very large number of such pistons were made, during the war, of an alloy containing 12 per cent of copper, the remainder being aluminum and impurities. At the ordinary temperature, this alloy in the form of a chill cast bar gives a tensile strength of rather less than 22,500 lb. per sq. in., and at 250 deg. Cent. this has fallen to less than 8000 lb. Even this compares favorably with the usual casting alloy containing about 13 per cent of zinc and 2.5 per cent of copper, which at the ordinary temperature registers a tensile strength of 15,000 lb. per sq. in., but falls, at 250 deg. Cent., as low as 4800 lb. This latter alloy, like all those containing any considerable proportion of zinc, is thus entirely unsuited for use in pistons, although—curiously enough—some German airplane engine pistons were found to contain about 9 per cent. of zinc. Investigation into the properties of aluminum alloys at high temperatures, however, soon led to the improvement of the alloys. A first step consisted in the introduction of manganese. An alloy containing 14 per cent of copper and 1 per cent of manganese was found to possess a very remarkable property. Its tensile strength at the ordinary temperature was about 10,000 lb. per sq. in., but while in all other aluminum alloys the strength falls off with temperature, in this alloy it was found to rise up to a maximum which was reached in the neighborhood of 250 deg. Cent., where this alloy gave a test of 11,000 lb. per sq. in. This alloy, however, undoubtedly suffers from too high a content of copper, and the stiffening effect of nickel was next studied. Finally, an alloy was evolved which contains 4 per cent of copper, 2 per cent of nickel and 1.5 per cent of magnesium, which in the chill cast condition shows a tensile strength of over 15,000 lb. per sq. in., and at 250 deg. Cent. still maintains a strength of 13,500 lb. per sq. in. More recently, by special heat treatment, the strength of this alloy has been increased to a very marked degree, and its future use for pistons is strongly indicated. It is, however, an alloy which undoubtedly requires special care in its preparation, but the difficulties are no greater than those inherent in the adoption of any new type of alloy, and they have been successfully overcome by aluminum founders on quite a large scale. Given a material of this order of strength at the working temperature, there would appear to be no reason, from the strength point of view, why the light alloy piston should be made of greater section at any point than that which serves well in cast iron. On the other hand, although adherence to the scantlings adopted with cast iron pistons will result in an appreciable saving

of weight, it will to that extent also lessen the power of the piston to conduct away heat from the combustion space. Curiously enough, it would seem that in the airplane engine the heat conducting power is of greater importance than a saving of weight. In the automobile engine, where compression ratios need not be pushed to the extreme, on the contrary, it is probable that a saving in weight of the pistons, by lessening the inertia stresses and generally reducing vibration, may offer greater advantages than the additional cooling power of a piston with thicker walls. Whichever side of this balance of advantages be taken as greater, it is obvious that the design of the piston itself should be carefully considered, not merely from the point of view of strength, but also from that of heat conduction. Wall thicknesses should be proportioned so as to correspond, at each point, with the quantity of heat which has to be conducted away, and a thickening of the piston walls, as a compensation for a removal or reduction in the size of the customary internal ribs, would seem desirable. Another important point, also, in regard to piston design is that the inner surface of the piston head should not be "pocketed"—i.e., it should be exposed as freely and directly as possible to cooling by splashing oil. There is also a further factor of design to be borne in mind, and that is facility of casting. Pistons should, wherever possible, be cast in chill (iron) molds with chill cores. These latter it is necessary to remove at the right moment as soon as the casting has "set," otherwise the contraction of the casting is liable to make it bind on the core and to split during cooling. The interior of the piston should therefore be so designed that a metal core made in two or three simple parts can be easily and quickly withdrawn when desired.

Shrinkage and Other Factors in Casting

As in other light alloy castings, defects are not unknown in the case of pistons cast in these materials. It was thought at one time that different aluminum alloys possess widely different degrees of shrinkage during solidification, but careful measurement has shown that this is not the case even in widely different alloys. In all of them, however, shrinkage is considerable and must be allowed for in making the castings. The necessity of removing a metal core at the right moment has already been indicated. Further, care is required to secure the solidification of the casting in the proper sequence. If thicker parts are connected together by thinner ones, provision must be made for "feeding" these thicker parts with liquid metal from some "gate" or "riser." If this is not done, the metal—still partly liquid—which has filled these thicker spaces in the mold becomes cut off from the rest by the earlier freezing of the adjacent thinner parts, and the subsequent contraction of the thicker portions leads to what is known as a "draw"—in reality a shrinkage cavity which is frequently distributed over a certain region in the form of sponginess. Piston castings containing such "drawn" places are very apt to be seriously porous. It is, accordingly, sound practice to subject piston castings to hydraulic pressure test before putting them into service. If a spongy "drawn" place should become exposed to the explosion gases, the piston is very likely to be damaged by erosion, the hot gases under pressure being forced into the pores and then rushing out again as the pressure in the cylinder falls.

At one time it was thought that the occasional failure of aluminum alloy pistons by what is known as "burning" could be ascribed to the existence of spongy places. Fuller experience, however, has shown that such "burning" can occur with perfectly sound pistons. In the great majority of cases such burning arises from defective lubrication leading to local heating. On the other hand, it seems probable that in some cases, at all events, the relatively very weak nature of the alloys used for piston castings is in reality to be blamed for these failures. Owing to the very soft, weak state of some of these metals at the working temperatures, particles become loosened on the heated surface. These are exposed to the flame of the explosion on all sides and are melted at the edges, thus giving rise to the idea that the burning of the piston is due to partial local melting of the more fusible constituent of the alloy (the aluminum-copper eutectic). Actually, the body of the piston does not approach the temperature required to melt this eutectic by several hundred degrees. At all events, where the very much stronger alloys now available are employed, this cause of "burning" will be eliminated.

Piston Pin Bushes and Piston Rings

There are two other points connected with the aluminum alloy piston which deserve mention here; these relate respectively to the piston pin bushes or bearings and to the piston rings. Taking the latter first, the usual practice hitherto has been to employ the ordinary cast iron ring with the light alloy piston, and this combination has worked satisfactorily. It has been suggested that the presence of these relatively poorly conducting rings between the piston and the cylinder lessens the flow of heat from the one to the other. This may be true to a very slight extent, but the greater part of the heat flow must take place through the broad surface of the piston skirt which takes its bearing upon the cylinder wall on the side toward which the piston is pressed by the obliquity of the thrust of the connecting rod. A realization of this fact suggests the importance of making this surface large enough—i.e., of not making the piston as a whole too short. Very short pistons have failed, not only because they did not produce efficient cooling but also because the bearing pressure against the cylinder wall became too high. Where this error is avoided, however, the aluminum alloy piston works extremely well in a cast iron or steel cylinder. An attempt has been made to use an aluminum piston in a cylinder of a similar light alloy, but although a certain degree of success has been claimed, no serious attempt to introduce such a construction into engine practice has yet been made. Reverting to the question of piston rings, however, there is a certain objection to the use of the iron rings, since their greater density causes them to "hammer" upon the walls of the grooves in the piston. In the course of time this action tends to widen the grooves, which successively intensifies the evil by allowing greater amplitude of motion to the rings. A curious metallic, ringing sound is sometimes heard from an engine in this condition. The use of light alloy piston rings has therefore been suggested, but no serious amount of experience with these is yet available, the main doubt being whether they would satisfactorily retain the requisite "spring" to maintain a gas tight joint with the cylinder.

Finally, the manner in which the piston pin is to be carried in the light alloy piston remains to be considered. A good deal depends upon whether the pin is to remain fixed in the piston, the rocking motion to be taken by the "small end" bearing of the connecting rod, or whether the pin is to "float"—i.e., to be free to rotate relatively to either the piston or the connecting rod. In the majority of aero engines the latter state of affairs prevails, and for that purpose the aluminum alloy piston is generally provided with a cast iron bush which is inserted in one of two ways: it is either "cast in" or screwed in. The latter method requires no comment, but it must be borne in mind that a tight screwed fit when cold is likely to

(*Continued on page 1301*)

Engineering Analysis of European Four Wheel Brakes

The four-wheel braking system is making great progress in Europe and the results achieved are worthy of serious attention from American Engineers. This article discusses the engineering features of the chief types and presents the results of tests recently made. Uniformity in size noted.

By W. F. Bradley and S. Gerster

ALTHOUGH brakes on the rear wheels, or on the rear wheels and transmission, are to be found on the vast majority of automobiles, the front wheel braking system is making such progress, particularly in Europe, as to be worthy the close attention of all American engineers. The movement is not at all new, for at various intervals during the last twenty years more or less spasmodic efforts have been made to introduce four-wheel braking. The last time any effort was made to promote the use of four-wheel brakes was about 1910, when the Allen-Liversedge brakes appeared in England and the French engineer Perrot produced the Argyll chassis with brakes on all four wheels.

The present revival, which dates from the Armistice, differs from the others by reason of the fact that the four-wheel braking systems are perfectly satisfactory. It cannot be denied that the Perrot system as used notably by Delage, Hispano-Suiza and Darracq, as well as the Isotta-Fraschini system, gives perfect results from the standpoint of the user and are infinitely superior to the best brakes on rear wheels and transmission. The fears that exist in the minds of certain motorists, and which are shared to some extent by engineers, that four-wheel braking systems require delicate adjustment and are apt to interfere with steering are absolutely unfounded. It has been proved over and over again that when properly laid out these braking systems require no more attention and are no more delicate than any others.

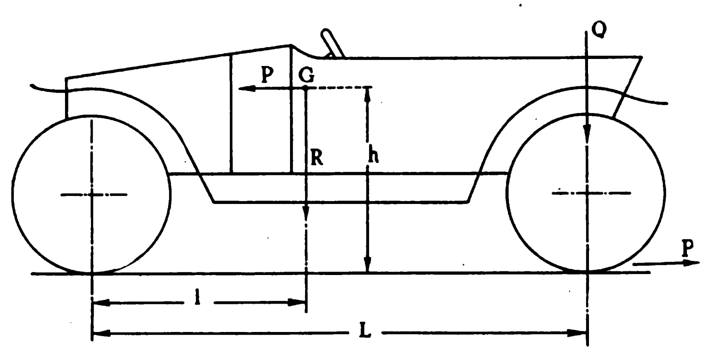


Fig. 1—Diagram of forces and reactions in braking.

Faculty of Adjustment

The cars with a four-wheel braking system are far above the average in the facility of adjustment. This, of course, is not due to the fact that brakes are placed on all the wheels, but because the complete design has been brought up to date and adjustment features have been given serious attention. As an example, Delage last year made a demonstration run of 3200 miles in six consecutive days, running in daylight only without a change of driver, and the total time for adjusting brakes and taking up wear was less than four minutes, and on no occasion was it necessary to use tools.

The only serious objection that can be made against four-wheel brakes is their extra cost. The front axle must be specially laid out for the extra stresses involved by reason of the braking effort, and numerous additional parts are required, this adding from $200 to $300 per chassis to production costs. It should be observed that up to the present four-wheel brakes have only been applied, in Europe, to high grade and costly automobiles, to which this additional production cost could be added without any great inconvenience. The full list of those actually in production on cars with four-wheel brakes is as follows: Delage, Darracq, Hispano-Suiza, Bellanger, Excelsior, Metallurgique, Piccard-Pictet, Isotta-Fraschini, Elizalde, all of these being high grade jobs. Delage, however, is now laying out a popular 10-hp. model, to be sold at a competitive price, to which front wheel brakes will be applied. This will be the first small car to be produced with this braking system. There is every reason to believe that next year other builders of small and medium cars will take up this feature. A development of some importance is that dealers, and particularly those with racing experience, now undertake to transform cars before delivering them to clients, by adding front wheel brakes. This modification is undertaken with the Perrot system, and in every case the front axle is changed.

Center of Gravity

The power of rear wheel brakes decreases as the wheelbase is shortened, as the center of gravity is raised, and as this centre is moved toward the front axle. The maximum braking effort obtainable with a car having brakes on all four wheels is found by the equation (1):

$$P = \frac{R \times l \times \mu}{L + (L \times h \times \mu)} \qquad (1)$$

This formula has been drawn up in accordance with Fig. 1, in which G is the centre of gravity; R the weight of the car; h the height of the centre of gravity; l the distance of the centre of gravity from the front axle; L the wheelbase; μ the coefficient of friction, and Q the weight on the rear axle. Equation (1) is the result of the two equations of equilibrium:

$$P = Q\,\mu \text{ and } Q = \frac{R \times L}{L} - P \times h^*$$

*See footnote on next page.

Fig. 2—4—Brake connection layouts on Bellanger, Excelsior and Delage.

on the supposition that the mass pivots around the point of contact of the front wheels with the ground.

By applying this formula it is seen that when the brakes are applied on the rear wheels only the rear axle is relieved of some of its load, which is transferred to the front axle. It is this transfer of weight from the rear to the front, when braking on the rear axle only, which is the cause of rear wheel skids with which every driver is familiar. This is so well known that skilled drivers frequently make use of the brakes to start a skid which will enable them to make a quicker turn than is possible with the steering wheel only.

Tests

When braking simultaneously on all four wheels, an effort can be obtained equal to the weight of the car multiplied by the coefficient of friction, this being the maximum retarding force. Taking a specific case of a car weighing 3306 lb., of which 1980 lb. on the rear axle, Perrot has calculated that the results shown in Table 1 would be obtained with rear wheel brakes only and with brakes on all four wheels.

It is interesting to compare these theoretical figures with the practical results obtained by the writer on a Darracq eight-cylinder car fitted with Perrot front wheel brakes. This was a chassis picked haphazard out of the shops and driven by a mechanic who had not been through any special training in the use of front wheel brakes.

With its loaded test body and two men aboard the weights were 2204 lb. on the front axle and 2623 lb. on the rear axle. Tests were made on an ordinary macadam road, on two different days, the first being very wet and the second being

Table I

	Distance covered, Rear wheel brakes*	Distance covered, Four wheel brakes
6 miles	3.5 feet	2.1 feet
20 miles	33.0 feet	19.0 feet
25 miles	57.0 feet	35.0 feet
40 miles	173.0 feet	102.0 feet
50 miles	229.0 feet	137.0 feet
60 miles	355.0 feet	210.0 feet

*See preceding page.—We think this expression should be

$$Q = \frac{R \times l}{L} - \frac{P \times h}{L}$$

The first term of the right hand side evidently represents the weight on the rear wheels with the car at rest and the second term the amount of weight transferred from the rear to the front wheels by the rear wheel braking action. The chassis may then be considered fulcrumed around the line of rear wheel ground contact and the moment of the inertia force around this line is Ph. This moment is balanced by the moment of the weight transferred to the front wheels whose distance from the line is L. Hence, if we call the transferred weight w, we have $wL = Ph$, and $w = \frac{Ph}{L}$. Another method of reasoning is as follows: The weight transferred cannot be expressed by Ph, because this is a moment expressed in pound-feet, and not a weight. To be made a weight this must be divided by a length again.—EDITOR.

Table II—Darracq Tests

	Four wheel brakes, Distance covered	Conditions
20 miles	28.4 feet	Dry Tarmac road
30 miles	40.0 feet	Dry Tarmac road
30 mlies	54.6 feet	Dry macadam
30 miles	65.6 feet	Wet macadam
40 miles	105.0 feet	Dry macadam
40 miles	108.0 feet	Dry Tarmac road
40 miles	98.4 feet	Wet macadam
50 miles	137.7 feet	Dry macadam
50 miles	147.6 feet	Wet macadam
60 miles	229.6 feet	Dry macadam
60 miles	239.5 feet	Wet macadam
	Rear wheel brakes only	
30 miles	122.9 feet	Dry macadam
40 miles	242.7 feet	Dry macadam
50 miles	319.8 feet	Dry macadam
60 miles	429.7 feet	Dry macadam

quite dry. On the dry day some tests were also made on a Tarmac type road, when it was found that quicker stops could be made up to 35 m.p.h., but beyond this speed the car could be stopped in a shorter distance on ordinary macadam. With the same chassis and on the same road, tests were made with the rear wheel brakes only with the results in Table II. The Darracq used for these tests has steel-lined aluminum drums of 16 in. diameter, with Ferodo lined shoes of 2 in. face width.

The figures were obtained by running the car at the required speed and dropping a sandbag overboard at the moment the signal was given to the driver to stop. The distance was measured from the point when the sandbag hit the ground (care being taken to see that the bag did not slide on the road) to the centre of the chassis. At high speeds it was rather difficult to obtain coordination between the dropping of the bag and the applying of the brakes, and several tests were made when this was in any doubt. It is obvious that these figures could be improved on, if desired, but their value lies in the fact that they are quite normal and represent the distances in which any driver could pull up with a car of this weight and this brake equipment.

It is interesting to examine these practical tests from a theoretical standpoint, calculating the distance in which the car can be stopped by the formula.

Distance required to stop:

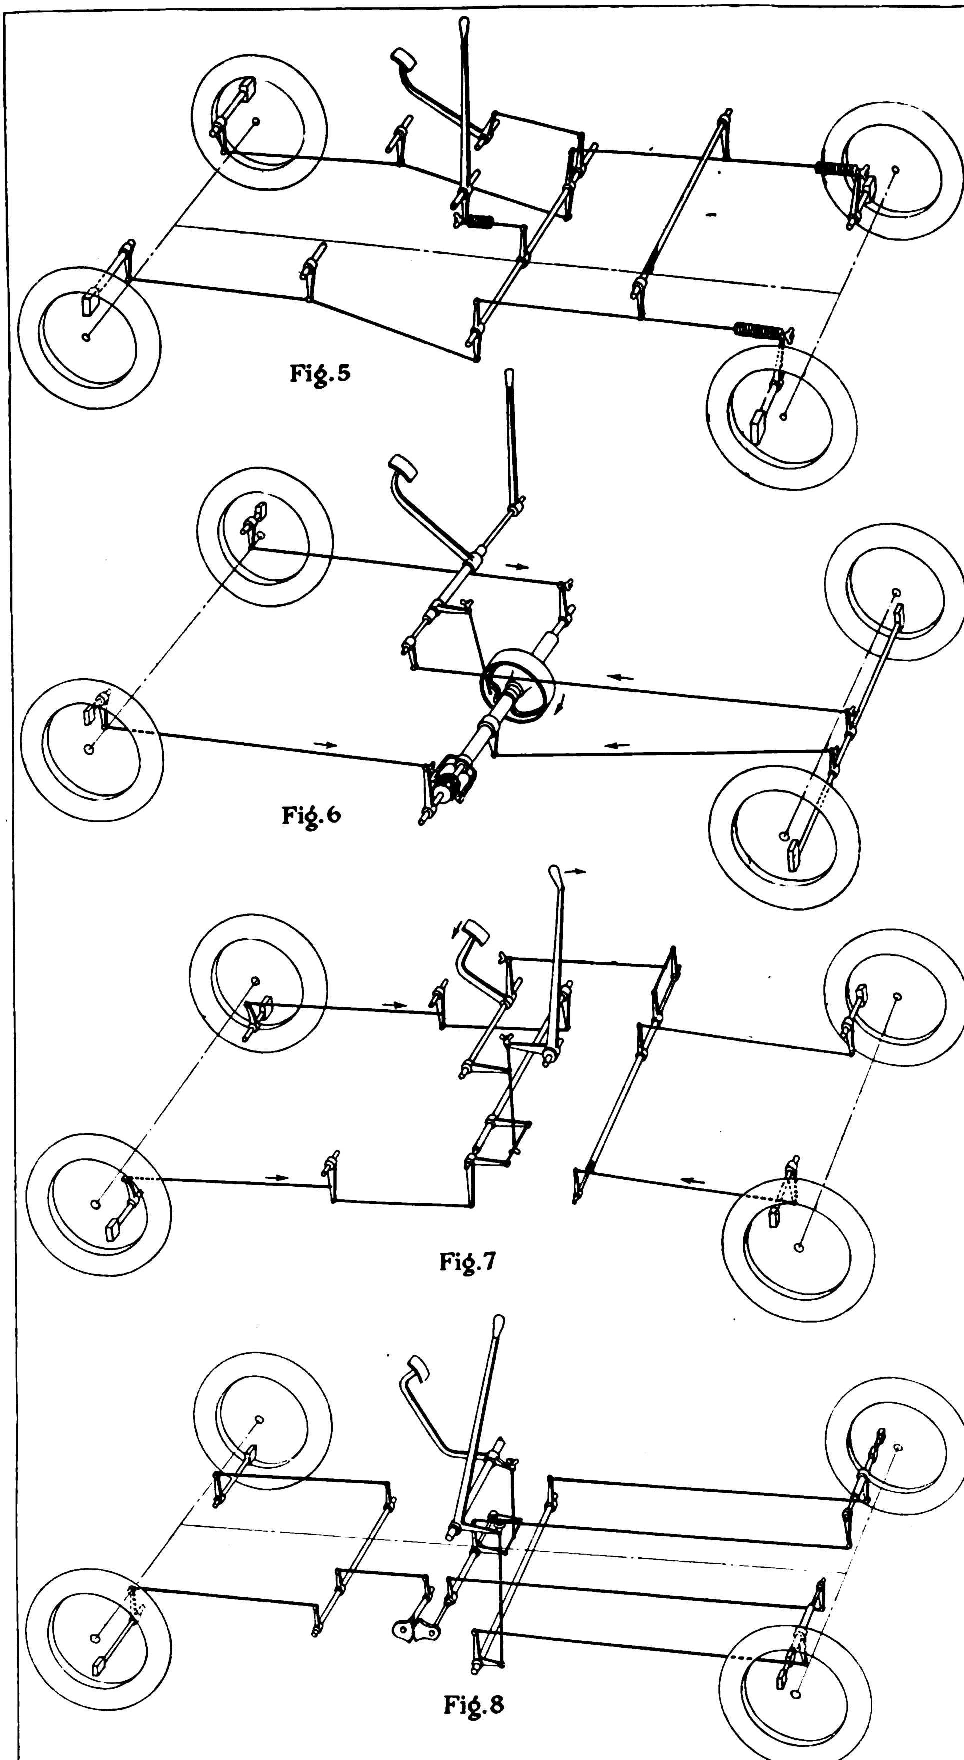
$$L. = 0.00393 \frac{P V^2}{F}$$

and taking as the coefficient of adherence of the wheels to the road 0.60. The comparative results are shown in Table 3.

Theoretical and Practical Relation

It will be observed that in the case of brakes on all four wheels there is very little difference between the theoretical figures and those obtained by the practical test. In the case of rear wheel brakes only the difference is greater, theory showing a much shorter stopping distance than is obtained in practice. This is due to the fact that when brakes are applied on the rear wheels, a portion of the weight on the rear axle is transferred to the front axle, and this reduction of weight on the rear is not taken into consideration in the calculations as usually made.

Claims have been made for considerably better performance than the above, and the following figures have been published as actual performance results for a hydraulic four-wheel braking system:



Figs. 5-8—Brake connection layouts on the Darracq, Hispano-Suiza, Isotta-Fraschini and Metallurgique. In each case there is one pedal and one brake lever.

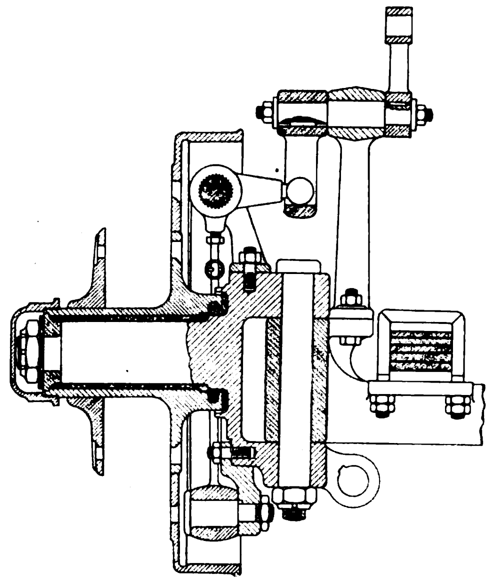


Fig. 9—Front Wheel brake of Dufour truck (1904).

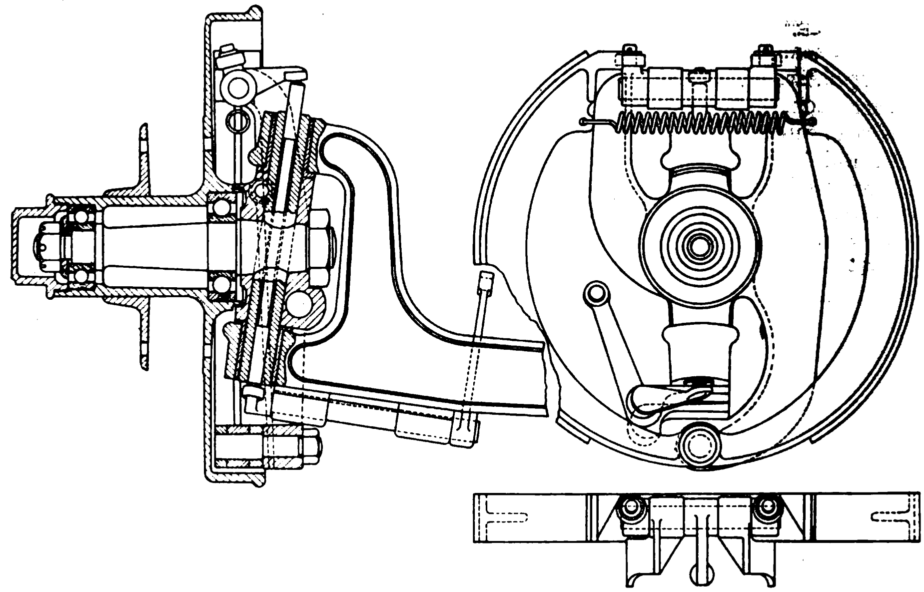

Fig. 10—Scat front wheel brake of 1910 showing inclined steering pivot.

Speed	Stopping distance
15 miles	9 feet
20 miles	16 feet
30 miles	36 feet
40 miles	64 feet
60 miles	144 feet

An examination shows that these are not performance but theoretical figures, for in every case from 15 to 60 miles an hour the coefficient of adherence is found to be 0.834. Obviously the coefficient of adherence is not absolutely uniform in any series of practical tests over a wide range of speeds. Further, the coefficient adopted is too high, 0.6 being a much more reasonable figure than 0.834. Figures such as these are harmful by reason of the wrong impression they convey regarding the value of four-wheel brakes.

On all cars built in Europe the brakes are applied simultaneously on the front and rear. There is no attempt to apply the rear wheel brakes ahead of the front wheel brakes, nor has any such arrangement been found necessary in practice. The only exception to the above is the Bellanger, Fig. 2, on which car the front and the transmission brakes are applied simultaneously by the pedal, and the rear wheel brakes are operated by side lever. Before the war Isotta-Fraschini had independent control of front and rear wheel brakes, the side lever being for the front and pedal for the rear. In practice the arrangement was not good, and the latest type Isotta-Fraschini brakes simultaneously on all four wheels. Various systems of brake application are in use: straight, diagonal, with equalizing mechanism, and without equalizers.

Table III

Speed	Rear brakes only		Four wheel brakes	
Miles	Theoretical	Practical	Theoretical	Practical
20	41.2	....	22.1	28.4
30	93.1	122.9	50.0	54.6
40	165.6	242.7	89.0	105.0
50	258.8	319.8	139.0	137.7
60	372.0	429.7	201.0	229.6

Excelsior (Fig. 3) brakes diagonally, so that the pressure is equalized at opposite corners, and if a brake cable

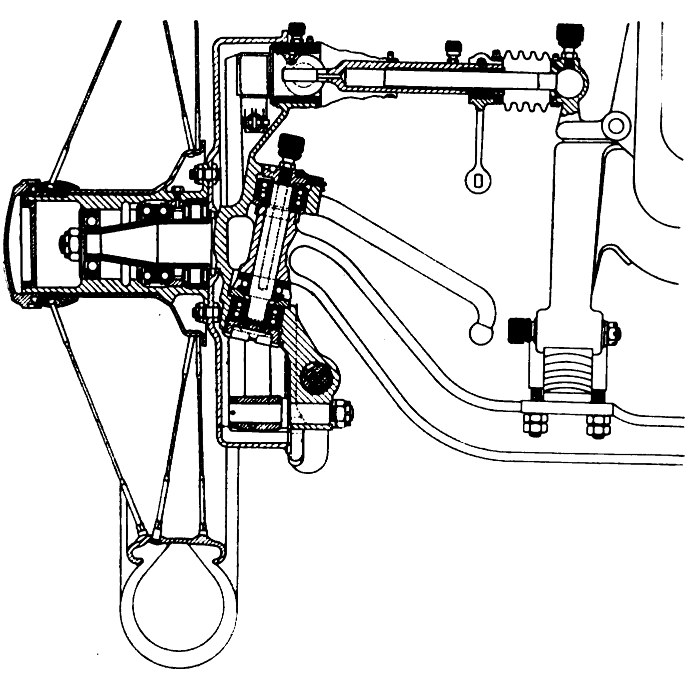

Fig. 11—Delage brake with cam above axle

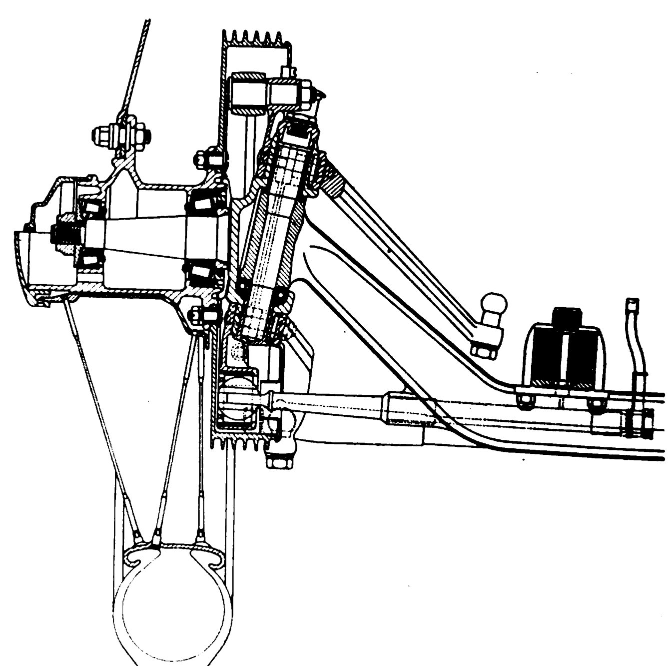

Fig. 12—Metallurgique brake with cam below axle

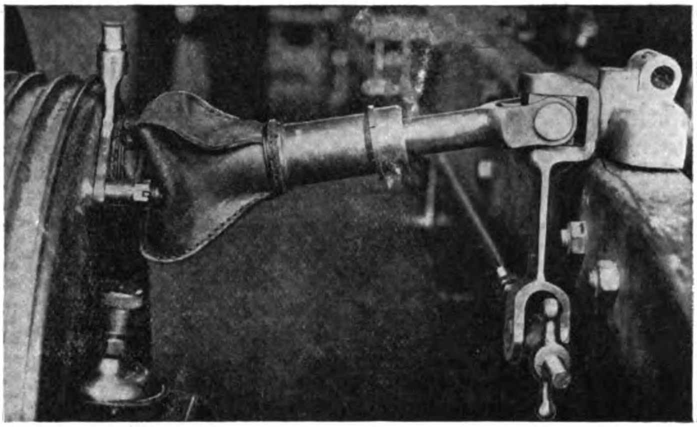

Fig. 13—Detail of Darracq brake operating mechanism on front wheel.

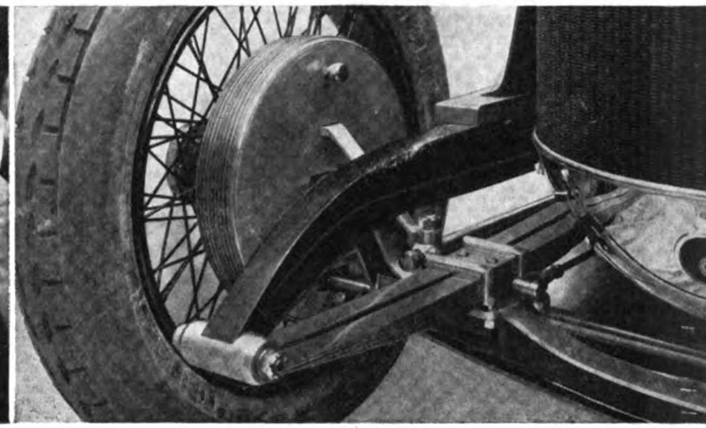

Fig. 14—Bellanger brakes and double springs.

broke a front and a rear wheel on opposite sides would still get the same braking effort. This is one of the patented features of Perrot's system, and was used by him on the first Argyll cars to have four wheel brakes. Curiously, however, those firms producing under Perrot license do not adopt this particular feature.

Delage, who has had more practical experience than any other firm on front wheel brakes, builds under Perrot license and brakes by pedal through two bevel type differentials (Fig. 4). There is a brake on the transmission, operated by hand, but its only practical use is to lock the car in a standing position. On the new 10-hp. type now going into production Delage has abandoned the transmission brake As under French law there must be two independent sets of brakes, it is assumed that the rear wheel brakes will be operated by lever as well as by pedal. Some such arrangement is necessary in order to lock the car in a standing position.

Darracq has simultaneous operation of the four brakes by pedal or by lever (Fig. 5), but unlike the Delage there is no equalizing mechanism. After long road tests of the two types it is difficult to determine which has the advantage in this particular respect. On the Darracq it is necessary to adjust the two front and the two rear wheels together, but once adjusted there appears to be no tendency for them to wear unevenly. On the Delage, on the other hand, any differences between the two wheels forming a pair will be taken care of by the differential. Obviously the Darracq is a cheaper production job.

Hispano-Suiza is the only one making use of a relay brake, as shown in Fig. 6. This device has been adopted in order to reduce the effort required to apply the brakes, and is successful to such an extent that the pressure required on the brake pedal is hardly any more than that for the accelerator. On the Hispano-Suiza all four brakes are applied by pedal, but the rear wheel brakes can be applied separately by lever.

Isotta-Fraschini brakes by means of pedal on all four wheels, or by means of the central lever, shown in Fig. 7. Metallurgique is rather special with the use of rear wheel drums having twice the width of those at the front and containing double brakes, one set being connected up to the front and operated by pedal, and the second set being controlled by hand. There is no brake on the transmission. The layout is shown in Fig. 8.

There is a certain historic interest in noting that one of the first front wheel brakes was used on the Dufour truck in 1904 (Fig. 9). This brake was very defective, for the axis of the steering pivot being a considerable distance from the point of contact of the wheel with the ground, there was a reaction on the connecting rod when the brakes were applied, and when one wheel was on dry ground and the other on a wet patch, there was considerable reaction on the steering gear.

When front wheel brakes came up again in 1910, on the Allen-Liversedge, the Argyll, and the Scat cars, the extended axis of the steering pivots cut the axis of the wheels at their point of contact with the ground, as shown in Fig. 10, which represents the Scat brakes of that period, so that the steering was not affected by unequal braking efforts on the front wheels.

All modern four-wheel brakes are on this principle, while the brakes themselves may be divided into two distinct classes—those built on the Perrot system with the cam and operating mechanism mounted above the axle, as shown in Fig. 11, on the Delage and as also used by Darracq and Hispano-Suiza, and those on the Isotta-Fraschini system with the cam below the axle. This latter design is adopted by Excelsior, Metallurgique (Fig. 12), Bellanger, and Piccard-Pictet.

With the Perrot system an extremely flexible connection is required from frame member to the brake drum. The brake camshaft is telescopic and is carried at its outer extremity on the frame member. Alternative methods of

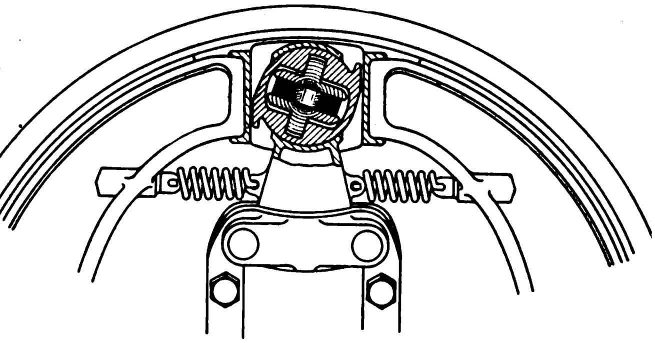

Fig. 15—Ball universal joint in brake cam on Metallurgique.

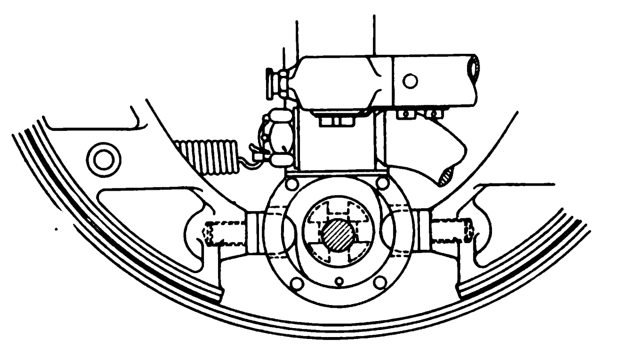

Fig. 16—Method of operating brake shoes on Bellanger.

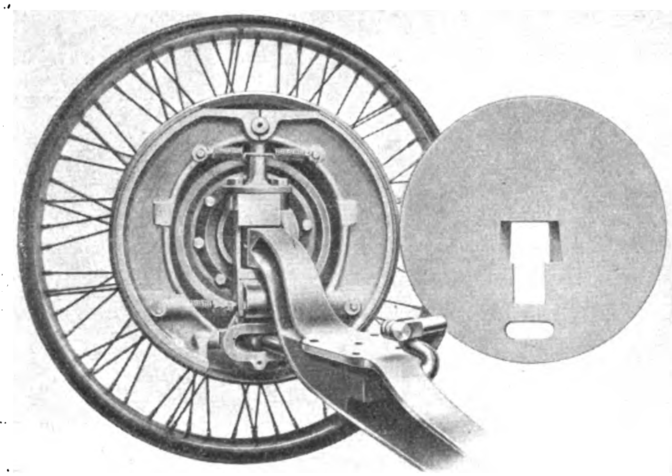

Fig. 17—Details of Bellanger brake.

mounting are shown in the Delage (Fig. 11) with a spherical connection on top of the frame member, and the Darracq (Fig. 13) with a yoke type of universal carried in the radiator support. On the latest Darracq the brake camshaft is mounted on the frame member, independently of the radiator support.

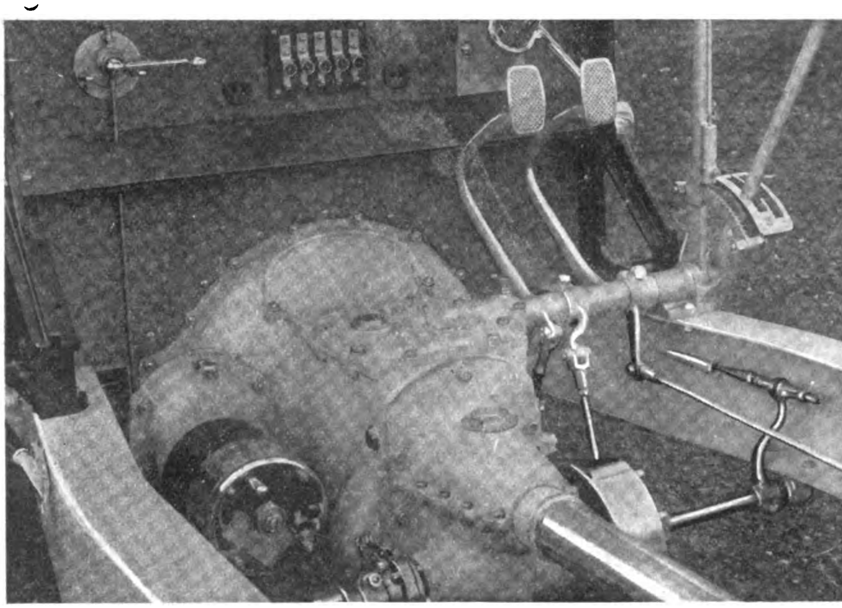

Fig. 18—Hispano-Suiza brake connections.

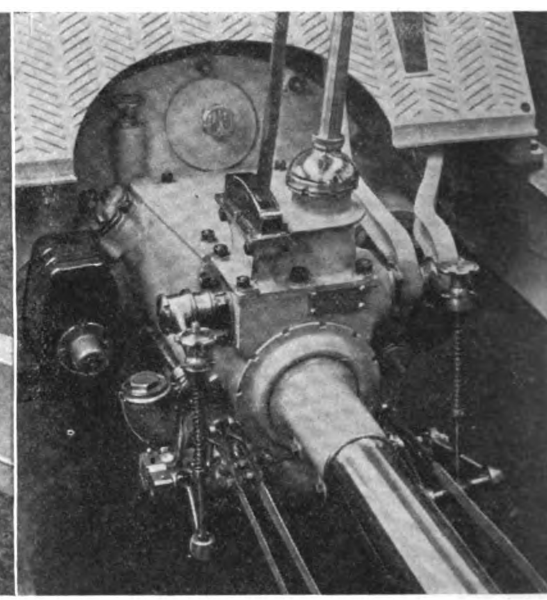

Fig. 19—Metallurgique brake adjustment.

The Perrot System

Advantages claimed for the Perrot system (Delage, Darracq, Hispano-Suiza, etc.) are that the whole of the brake operating mechanism being placed at the highest point there is the maximum protection against mud and dust. It is quite an easy matter, by the use of a leather gaiter, to completely protect the moving parts of the telescopic camshaft. The braking is not seriously affected with this design in case the front axle is bent in an accident, whereas with the brake camshaft mounted in the axle any accident to this latter makes the brakes inoperative, and the breakage of the main leaf of the front spring renders the brakes on the front wheels useless. As a remedy against this Bellanger uses double springs at the front (Fig. 14), held to the axle by a single pair of clips. It is most unlikely that two main levers will break simultaneously.

Generally a stop is fitted behind the rear shackle of the front spring to prevent the axle moving back in case of spring breakage. A third claim for the Perrot system is that it allows of the use of an axle with a bigger road clearance than is possible when the brake operating mechanism is carried in the axle itself. The objection can be raised against some of these designs that they are not very suitable for cheap production. An example is the spherical universal in the brake cam on the Metallurgique, shown in Fig. 15. The method of brake shoe operation on the Bellanger is shown in Fig. 16, with details of the brake in Fig. 17.

Uniformity in Size

On all the European high grade cars at present employing four-wheel brakes there is a large degree of uniformity in size, the drums varying in diameter from 15 to 16 in. and the shoes having a width of from 2 to 2½ in. on the Delage, Darracq, Hispano-Suiza, Metallurgique, Excelsior, Bellanger, and Piccard-Pictet cars. In all cases the brakes are internal expanding, the external contracting brake being quite unknown in Europe. Large use is made of ribbed cast aluminum drums with steel liners and aluminum shoes, this combination of metals being adopted in

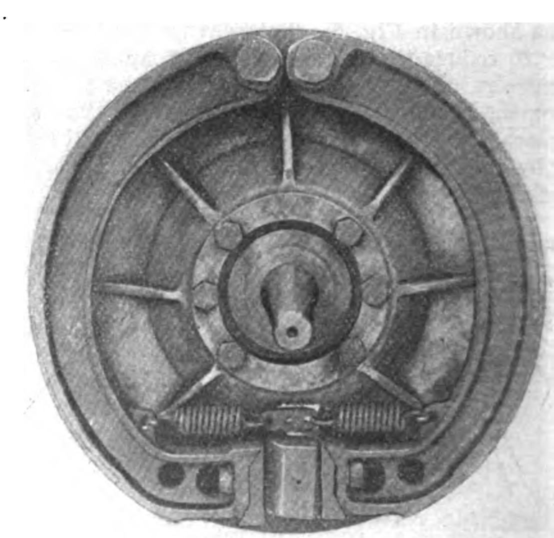

Fig. 20—Excelsior brake showing micrometer adjustment.

order to reduce unsprung weight to the lowest limits. Ferodo brake lining is used in the majority of cases, and while this gives fair satisfaction, it is admitted that the ideal lining has yet to be found. One of the objections raised against Ferodo is that when it becomes hot under strenuous service it assumes a spongy, almost rubbery character, with a loss of efficiency. Excellent results are claimed by Excelsior with alternating bands of cast iron and Ferodo. The dust from the iron shoes becomes impregnated in the fabric lining and improves its general efficiency.

Adjusting Arrangements

Much of the detail of these high-class braking systems is worth studying, and particularly the attention which has been given to arrangements for taking up wear and rapidly adjusting the brakes. On Delage and Darracq cars the normal wear is taken up by four butterfly nuts, two at the front and two at the rear of the chassis, shown in the case of the Darracq in Fig. 13. Delage also uses a bevel gear type of differential as balancing gear, the whole being in an aluminum housing. The use by Hispano-Suiza of steel cables for the front wheel brakes only is interesting, these cables going through guides in the frame members (Fig. 18), and adjustment being by butterfly nuts reached by lifting up the floor boards. Metallurgique unites all the brake adjustment at the rear of the gearbox, shown in Fig. 19. This firm also employs steel ribbons in place of the more commonly used brake rods, but to prevent rattle they are mounted vertically. Excelsior is the only firm using cable connections throughout, this choice being justified by the diagonal operation of the brakes. This firm provides for adjustment between the spherical cam and the brake shoes by having the hardened steel face pieces in the form of wedges with notches giving adjustments of one millimeter, as shown in Fig. 20.

French Semi-Diesel Competition

By W. F. Bradley

LITTLE public interest having been displayed in the semi-Diesel engine competition for French productions only, announced by the Automobile Club of France, this event has been withdrawn and new rules have been issued for a competition open to foreign nations on invitation. Those who are invited to take part are England, Belgium, Denmark, United States, Holland, Italy, Norway, Sweden and Switzerland. The bench tests will begin on October 15, 1921, and entries are received until August 1.

Four different classes of semi-Diesel engines are provided for under the rules, as follows:

Class 1, from 2½ to 9 hp.
Class 2, from 10 to 24 hp.
Class 3, from 25 to 34 hp.
Class 4, from 35 to 50 hp.

In the two latter classes the engines must have at least two cylinders.

The object of this competition is to encourage the development of semi-Diesel engines suitable for use on fishing boats, on agricultural tractors and for general stationary work. There are no restrictions on the type of fuel used, which may be either a petroleum by-product or derived from coal tar, on condition that it is readily obtainable commercially. Water injection is permitted.

The engines must develop their rated power at 450 r.p.m. for the first class; 400 for the second class; 350 for the third class, and 300 for the fourth class, the tolerances being 20 per cent plus or minus. While no weight limit is fixed, the total weight of the engine will be taken into consideration in making the awards. Fuel consumption must not exceed 450 grammes per horsepower-hour for fuel having a calorific value of 10,000 calories.

There will be six practical bench tests, as follows: (1) A 3-hour test under full load, followed by a similar test on the following day, it being absolutely forbidden to touch the engine between the two trials; (2) a 3-hour test at the same speed as the first test, but under half load; (3) a 3-hour test at half the maximum speed, with the load corresponding to this engine speed; (4) a 1-hour test at half maximum speed and at one-eighth maximum load; (5) a 1-hour test without load; (6) various starting tests, during which the engine must be started up from cold with the fuel used in normal running in a maximum time of 20 minutes. There will also be a series of tests at varying speeds and with quick changes from these different speeds. The ease with which the engine can be started up and reversed, the absence of noise and vibration and the east of starting after a long stop will be taken into consideration by the jury.

Awards in this competition will be made by the attribution of points for construction and operation on the following basis:

Construction.	Points.
Quality of construction	0 to 100
Ignition	0 to 100
Ease of dismounting and inspection of various parts	0 to 40
Interchangeability of parts	0 to 40
Lubrication	0 to 40
Ease of inspection and cleaning of valves	0 to 40
Joints for valve seats and piping	0 to 40
Operation.	**Points.**
General operation (noise, vibration, etc.)	0 to 200
Ease of starting	0 to 200
Ease of control	0 to 400
Consumption of lubricating oils	0 to 100
Fuel consumption under full load	0 to 500
Fuel consumption under half load	0 to 200
Fuel consumption without load	0 to 100
Fuel consumption under full load (half speed)	0 to 200
Fuel consumption with one-eighth load (half speed)	0 to 100
Weight per horsepower	0 to 100
Price of the engine	0 to 400
Ability to withstand racing	0 to 100

Some attention is being paid by French manufacturers to the development of semi-Diesel engines, not only for stationary work, but for use on trucks and agricultural tractors. Peugeot is working on this problem; Delaunay-Belleville has brought out an agricultural tractor with a semi-Diesel engine, and the S. M. I. M. Company has a truck engine in operation.

THE longest motor transport line in Spain was recently opened from Santander, on the shores of the Bay of Biscay, to the town of Burgos. The distance between the two towns is 96 miles, and the road is of a very difficult character, for starting from the sea level the route rises to an altitude of 3280 feet at Puerto del Escudo and drops down abruptly to Burgos. In certain places 18 per cent gradients are encountered. This line will carry both passengers and goods, the regular daily service being assured by four Fiat omnibuses and four lorries of the same make. The opening of this service was made the occasion of much local rejoicing, and a crowd estimated at 20,000 persons gathered to see the arrival of the first cars.

Tolerance Systems for Cylindrical Fits

The tolerances allowed must agree closely with the requirements if the limit gaging system is to be utilized to its fullest advantage. This article discusses the various tolerance systems used in connection with cylindrical fits and points out the various factors involved in each.

By P. M. Heldt

MANUFACTURE on the interchangeable plan was made possible by holding to close limits of measurement those parts which have to fit other parts, the dimensions being checked by means of limit gages. The manufacture of parts to limits is not at all new, but has been the accepted practice in the automobile industry during the past eight or ten years. But in the setting of the tolerances for different classes of work there has been in the past very little method, and there has been no uniformity in the practices of different shops. It is evident that the full advantage of a limit gaging system cannot possibly be obtained unless the tolerances allowed agree closely with the requirements. Of course, the average fit becomes better the closer the tolerances are made, but, unfortunately, exceedingly close tolerances mean high cost of production and high wastage. On the other hand, if the tolerances are made too large the parts will not go together properly and may require hand-fitting in assembling—the very thing it is desired to avoid by the limit system—or the rejection of parts in the assembling department which were passed by the inspectors.

There are two ways of looking at the matter of tolerances. In the first place, there would be no use in setting tolerances so close that the workmen cannot work to them. This was the point of view generally taken in earlier years, when the shop foreman was intrusted with the task of fixing the tolerances to which he thought the shop could work on any particular part, and these were set down on the drawings.

In recent years it has been found, however, that a shop force, provided it is furnished with suitable equipment and the working conditions are right, particularly as regards lighting, can be quickly trained to work to almost any degree of precision that may be called for. Hence in future there is no reason why the tolerances should not be determined solely with regard to the requirements of the work in hand. It will then be possible to standardize tolerances, so that parts made in different shops will be interchangeable. The need for such standardized systems of fits and tolerances became very apparent during the war when contracts for machine parts were let to an unprecedented extent. Had a complete system of standardized fits and tolerances been in existence at that time, untold trouble and waste would have been avoided. Although, as stated above, a shop force may be trained to work to any degree of precision that may be called for, the higher the precision the more expensive the work, and the tolerances should be set no closer than the purpose for which the part is intended actually necessitates.

When a shaft fits into a bore the character of the fit depends entirely upon the relation between the diameters of the shaft and bore. The question is sometimes asked, How large must a shaft be in order to just go into a hole of 1 in. diameter? The answer is that it must be 1 in. in diameter, in which case it will fit snugly into the bore, giving what is known as a push fit. If the shaft is made the least bit smaller in diameter it will enter the bore with a certain degree of freedom, whereas if it is the least bit larger it will require considerable force to cause it to enter. The degree of freedom on the one hand and the amount of force required on the other vary continuously with the difference in the diameters of shaft and bore. This difference, known as the allowance, may have an endless number of values, and there is, therefore, an endless number of degrees of fit that can be obtained. The necessity for determining upon a limited number of classes of fit arises from the fact that it is commercially impossible to make either shafts or bores to absolutely definite dimensions.

Tolerances must be set on both the bore and the shaft diameters. For instance, if for a particular part we set limits of 0.999 and 1.000 for the shaft and 1.000 and 1.001 for the bore, then it is possible for a 1.000-in. shaft to come together with a 1.000-in. bore and a 0.999-in. shaft with a 1.001-in. bore, representing the two extreme cases. There will always be such differences in fits of a certain class, but the extremes must not be far enough apart to completely change the character of the fit.

Three Fundamental Classes

In various systems there are different classes of fits. The British, in their deliberations on the subject, distinguished between three fundamental classes, viz., running fits, in which the bore is greater than the shaft diameter; interference fits, in which the bore is smaller than the shaft diameter, and transition fits, intermediate between the two. This classification is handy for purposes of discussion, but all actual systems of fits comprise a greater number. The lowest number is four, namely, running fit, sliding fit, push fit and force fit. A system of allowances and tolerances covering four fits is given in Table I, this having been evolved by J. E. Reinecker, a German machine tool manufacturer, and is in millimeters. The allowance is the difference between the shaft diameter and bore, being positive (+) when the shaft diameter is greater than the bore and negative (—) when the shaft diameter is less than the bore. The tolerances in this system are equally distributed on both sides of the nominal dimensions. This Reinecker system is typical of early attempts to standardize fits. Of late years the subject has been greatly elaborated.

As the class of fit depends upon the average difference in diameter between bore and shaft, it follows that if the bore is held constant for all classes of fit the shaft diameter must vary with the class of fit, and, conversely,

Table 1

Reinecker System of Tolerances

Diameter Ranges	Allowances for Different Classes of Fit: Running Fit	Sliding Fit	Push Fit	Force Fit
10– 16	—0.02 to —0.045	—0.01 to —0.035	+0.005 to —0.02	+0.02 to —0.005
17– 29	—0.025 to —0.06	—0.01 to —0.045	+0.01 to —0.025	+0.03 to —0.005
30– 50	—0.03 to —0.075	—0.01 to —0.055	+0.01 to —0.035	+0.04 to —0.005
51– 80	—0.035 to —0.09	—0.015 to —0.065	+0.01 to —0.04	+0.05 to —0.005
81–120	—0.045 to —0.11	—0.015 to —0.075	+0.015 to —0.045	+0.06 to —0.005
121–200	—0.055 to —0.13	—0.015 to —0.08	+0.015 to —0.05	+0.07 to —0.005

Limits for Bore and Shaft Diameter

Diameter Ranges	Bore Tolerance	Shaft Diameter Tolerances: Running Fit	Sliding Fit	Push Fit	Force Fit
10– 16	0.015	0.010	0.010	0.010	0.010
17– 29	0.020	0.015	0.015	0.015	0.015
30– 50	0.025	0.020	0.020	0.020	0.020
51– 80	0.030	0.025	0.020	0.020	0.025
81–120	0.035	0.030	0.025	0.025	0.030
121–200	0.040	0.035	0.025	0.025	0.035

In the lower table the figures represent the total tolerance or difference between the upper and lower limits.

if the shaft diameter is held constant for all classes of fit, the bore diameter must vary. The first system is known as the bore basis and the second as the shaft basis. The superiority of the one or the other of these alternate systems has been a much-discussed question. Superficially considered, there seems to be no great advantage one way or the other, but when the problem is closely looked into many points of difference come to light. Account must be taken, in the first place, of previous practice, as a large amount of capital is invested in gages, reamers, arbors, etc., and in case of a change in basic dimensions these tools are rendered useless.

Bore Basis and Shaft Basis

In England the subject of fits and tolerances was handled by a subcommittee of the Committee on Machine Parts, Their Gaging and Nomenclature, appointed by the British Engineering Standards Association, and this committee, after several sessions, decided to adopt the bore basis. In Germany, where the subject is handled by a subcommittee of the Standards Committee of the German Industry, the conclusion was reached that both the bore basis and the shaft basis would have to be retained.

The chief reason for the preference of the bore basis over the shaft basis is that the bore is usually finished by a reamer and also must fit a mandrel, and if the bore is constant for all classes of fit it saves a great deal on reamer and mandrel equipment. The German committee found it impossible to agree on a single system, as important branches of the German industry had been working on the shaft basis and, in view of their investments in gages and tools, they wanted to continue to do so, whereas the machine tool industry and the precision industry felt they could not give up the bore basis.

Advantages of Shaft Basis

The shaft basis has advantages in those branches of industry where cold rolled steel is used to quite an extent, as with this system fits of different kinds can be made on the same shaft without any offsets or shoulders on the shaft. This entails cheaper construction, hence is to be preferred in many lines, such as shop equipment, agricultural machinery, etc. In many cases it is a much easier matter to replace a smooth than a stepped shaft. The shaft basis was also claimed to be preferable where ball bearings are used, because German ball bearing manufacturers want to turn out their bearings with only one inner and one outer diameter for each size, with the zero line in both cases as the limit. This places the outer race on the shaft basis and at the same time gives a press fit for the inner race on the standard shaft. It is believed that the shaft basis offers a balance of advantages to firms specializing on a narrow line of products, whereas the bore basis is to be preferred by shops taking in almost any kind of work, which must, therefore, have a large range of equipment.

Disposition of Tolerances

Another question that comes up in the consideration of fits is the disposition of tolerances. Formerly it was customary to distribute these equally on both sides of the nominal dimension, and such dimension figures as 2.500 ± 0.001 in. were commonly used. But this sometimes led to trouble. Suppose, for instance, that a designer wanted a running fit on a 1¼-in. shaft and figured that an allowance of 0.001 was necessary to give clearance for the oil film. If at the same time he figured on plus and minus tolerances of 0.001 in. each, he would dimension his bore 1.250 ± 0.001 in. and his shaft 1.249 ± 0.001 in. However, in that case his minimum bore would be 1.249 in. and his maximum shaft 1.250 in., and instead of getting a running fit he would get a press fit in this extreme case. Such mistakes are not unavoidable with symmetrically disposed tolerances (the bilateral system), but they are more likely to occur with them than with the unilateral system.

Most of the arguments that have been adduced in favor of symmetrically disposed tolerances have to do with considerations of established practice. This was the common system some years ago and most of the firms which then adopted the limit gage system are equipped for it. These firms may not be very numerous, but, on the other hand, they include some of the largest concerns in the machinery industry. If the nominal size were made the low limit for bores, that is, if the tolerances were entirely disposed on one side of the nominal size, then all mandrels and reamers made for standard holes would be rendered useless. In Europe the point has been raised that ball and roller bearings as at present standardized can in many cases most easily be dealt with if the limits of the holes to receive the outer races are controlled by gages having at least one minus limit. However, in a set of shaft and housing fits proposed to the Standards Committee of the S. A. E. last January by a subcommittee largely composed of representatives of the bearing industry, housing bores with only plus tolerances were recommended. For the shafts also only positive tolerances are recommended. It has further been argued against the introduction of tolerances all to one side of the nominal dimensions that the introduction of any new system necessarily entails much extra control and work which is hardly warranted by the theoretical gain put forward in favor of the change.

An argument of a different character put forward in favor of the bilateral system is to the effect that where the bore basis is used it results in holes nearer, on the average, to the standard size. Where the low limit is the nominal size no hole can possibly be of standard size unless the "go" end of the gage be forced into the hole, which in that case will be of exactly the same size as the gage. Under such conditions there is no margin for error, and the operator, to obtain the desired result, namely, a standard hole, is obliged to exercise extreme care. Such use, moreover, is very injurious to the gage. In order to preserve the accuracy of the gages the pieces should enter the "go side" freely and the operator should be given full opportunity to take advantage of the permitted tolerance. With plus and minus limits both these advantages can be obtained, while the majority of holes produced will be very close to the standard size.

It is a rather strange fact that whereas England quickly reached a decision in the question of shaft basis vs. bore basis, which had proved a stumbling block in Ger-

many, at least in the sense that it was found impossible to adopt one of the two to the exclusion of the other, Germany disposed quickly of the problem of the disposition of tolerances on which no decision could be arrived at in England. In the German system the nominal dimension is the maximum dimension of the shaft where the shaft basis is used, and the minimum dimension of the bore with the bore basis.

In England representatives of the mechanical industries as late as the latter part of 1919 seemed to be divided into two substantially equal camps with no side willing to yield, for a committee report issued at that time stated that no decision could be made until further light had been thrown on the subject. However, recent private reports are to the effect that since that time there has been a marked change in England in favor of the unilateral system.

Advantages of the Bilateral System

The chief advantage claimed for using the zero line as the limit is that it is clearer than the system of symmetrically disposed tolerances. With the former system and the bore basis the shafts for all fits which are stationary, in the sense that there is no continued motion between the parts in operation, are given a positive deviation, those for all running fits, negative deviations. On the contrary, on the shaft basis the bores for running fits receive plus deviations, those for stationary fits minus deviations. The sign of the deviation therefore characterizes the kind of fit. Another advantage resides in the fact that one of the limiting dimensions is a standard dimension. The "go" side of all gages is a standard dimension for all qualities of fit. This facilitates the introduction of such a system by firms which previously made use of standard gages.

Qualities of Fit

It is obvious that not all industries can make use of the same quality of fits. Corn shellers, for instance, do not have to be built as accurately as aircraft engines. In the coarser grades of work where a running fit is wanted it is essential that the maximum shaft diameter be slightly less than the minimum hole diameter, but it does not matter so much if there is considerable clearance between the minimum shaft diameter and the maximum bore. Opinions as to the number of qualities needed differ. At the meeting of the British Committee above referred to some representatives thought that four or five qualities of work (degrees of fineness of tolerance) would be needed, while others thought three would be sufficient. In France only two qualities are in use. The Germans have adopted four qualities.

The system of standard cylindrical fits as worked out by the Standards Committee of the German Industry comprises eight classes of fit—press fit, light press fit, push fit, sliding fit, close running fit, running fit, free running fit and loose running fit—and four qualities of fit—coarse fit, plain fit, precision fit and high precision fit. The high precision quality goes together only with the sliding, push, light press and press fits. Precision fits are specified for all eight classes of fit. Plain fits are specified in conjunction with four classes of fit, viz., loose

running, running, tight and centering. Coarse fits are specified in connection with only two classes of fit, coarse running and tight.

Variation of Tolerance With Diameter

Naturally the allowances as well as the tolerances must increase with the diameter of the piece. At a meeting of the British Committee held in the fall of 1919, the view was expressed that further experimental work was needed before the basis on which allowances and tolerances should be determined could be settled, but those in attendance were of the opinion that the formula

$$\text{Allowances} = a + b\sqrt{D}$$

would give suitable results and might be accepted provisionally, a and b being constants and D the diameter. On the other hand, the German Committee adopted the expression

$$0.005\sqrt[3]{D}$$

for the unit of tolerance which serves to measure the tolerance, allowance, clearance, interference, etc. This is supposed to be the minimum permissible clearance between shaft and bore when using a light lubricating oil, taking into account the extreme wear of the "go" side of both the plug and caliper gages. Such a tolerance unit is a convenience, as it permits of tabulating the whole system of fits without giving the tolerances for many different ranges of size. For a 1-in. shaft this tolerance unit figures out to 0.00058 in. In the German standard system of fits all tolerances, clearances and interferences are given in multiples and fractions of the tolerance unit.

Wear and Marking of Gages

The German Standards Committee has also considered and set limits for the permissible wear of gages. These limits are as follows: 0.25 tolerance unit for a tolerance of 1 unit; 0.35 tolerance unit for a tolerance of 1.5 units; 0.40 unit for a tolerance of 2 units; 0.50 unit for a tolerance of 2.5 units, and 0.60 unit for a tolerance of 3 units.

In order that there may be no confusion between gages for different quality of fit the gages are to be given a coat of enamel of different colors, the colors chosen being as follows:

High precision fit gages, azure blue.
Precision fit gages, black.
Plain fit gages, "postal" yellow.
Coarse fit gages, light green.

The "no go" side of all gages will be painted a brilliant red. The nominal size is stamped on the gage, as well as letters denoting the class and quality of fit and whether it belongs to the bore basis or shaft basis system.

Distribution of Errors Over Tolerance Range

An interesting investigation of the distribution of errors when working to limit gages has been made by John A. Prestwhich & Co. of Tottenham, England. This concern uses the bilateral system of fits. In that case the dimension midway between the limits is the one desired by the designer, and it might be expected that the same number of parts would be over the standard as below the standard size, the same as in the case of a marksman shooting at a target a large number of times there will be the same number of hits to the right as to the left of the bullseye. The theoretical distribution of errors in such a case is given by the Gauss equation of probability represented by curves A, Fig. 1. Prestwhich & Co., by means of a highly accurate liquid gage measured up 74 finished crankpins and found that these

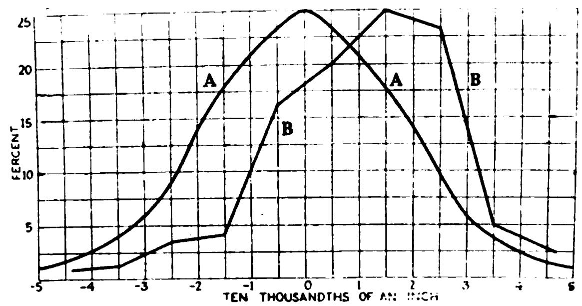

Fig. 1—Distribution of errors within permissible limits.

varied as shown by curve B, Fig. 1. The abscissas show the deviations from the standard size in ten thousandths of an inch, the tolerances being + and — 0.0005 in., whereas the ordinates show the percentage of the total number of pins between the limits represented by adjacent verticals. It is seen that this curve is displaced to the probable error curve by about 0.00015 in. This is easily explained, because in turning down a shaft the workman does not make any special effort to obtain the standard size but merely to come within the specified limits. On approaching the upper limit he gets very cautious, and as soon as he has reduced the diameter below this limit he stops because he has met the requirements. He keeps away from the lower limit for fear of going beyond it. There is, therefore, a natural bias toward the upper side, and the reasoning on which the curve of natural errors (A) is based does not apply to this case. Prestwhich & Co. draw the conclusion that if the tolerances had been set at + 0.00035 and — 0.00065 instead of at ± 0.0005 in. a great number of the shafts would have been of the standard size and the accuracy in general would have been closer.

Standard Tolerances in Engineering Contracts

Undoubtedly, once a standard system of tolerances is adopted it will be used to a large extent for acceptance inspection and specified for this use in contracts. All that is necessary is to mention the number or letter of the standards sheet in the contract, stating that parts will be accepted on the basis of inspection according to the particular standard. In this connection account must be taken of the wear of the "go" side of gages. Cases might occur where the manufacturer's inspection department used a gage worn nearly to the permissible limit, but the customer's inspector might use a new gage and reject parts which had been passed by the manufacturer's inspection department. In order to be thoroughly practical a system of fits must specify the allowable wear of the "go" side of gages and parts must be accepted if they don't exceed the measurement of the new gage on the "no go" side and the measurement of a worn gage on the "go side." In the German system the limits given in the standards sheets are working limits and they may be exceeded by the contractor by the amount of gage wear permissible. If any special tolerances are given in contract drawings they represent acceptance values or guarantees. It is the intention in Germany to have the standards adopted as legal by Parliament so their use in commercial contracts will be binding.

The German system of fits has been adopted by the Austrian and Swiss standards committees. In England the movement seems to have reached a stage of deadlock, owing to inability to agree on the question of disposition of tolerances, but there is no doubt that it will be taken up again in the near future, especially if other countries settle the matter in a satisfactory way.

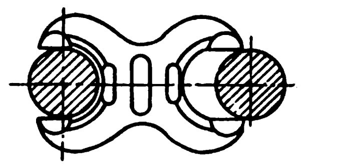
GERMAN INDUSTRIAL STANDARDS	**Precision Fit** Shaft Basis	G. I. STANDARD **40**

Abbreviated Designation for Shaft—fN

The precision fit is applicable to the running fits—loose running fit, free running fit, running fit and close running fit, as well as to the sensitive fits—sliding fit, push fit, light press fit and press fit. But the latter must be machined according to the high precision standard, G. I. Standards 48 to 51, if particularly rigid demands are made with regard to similarity of fit.

"Go" Side

The gage must go over the shaft by reason of its weight alone.



"No Go" Side

It must be impossible to pass the gago over the shaft and it must at most grab the shaft.

Dimensions in MM.

Diameter Ranges	New Gage Deviations Upward	New Gage Deviations Downward	Worn Gage Go Side Permissible wear	Worn Gage Go Side Deviation	Gage
	Go Side	No Go Side

Tolerance Units	0	− 1	0.25	+0.2	

The deviations of this sheet are identical with those of the sliding fit shaft of the bore basis system according to G. I. Standard 23.

This sheet also specifies the shaft basis shaft for high precision fits.

Sample German standards sheet giving tolerances for precision fits on the shaft basis.

Using German Tolerance Chart With English Measures

The German tolerance unit is equal to 0.00058 in. for a nominal diameter of 1 in. Using the chart of the system, it is an easy matter to calculate the limits in inches for any nominal diameter, class and quality of fit. Suppose that the bore basis is to be used and it is desired to find the necessary limits for a 1.5-in. shaft and bore which are to be a running fit of precision quality. Referring to the chart, the lower limit for the bore is found to be the zero line, that is 1.5 in. The upward deviation is 1.5 tolerance units. This amounts to

$$1.5 \times 0.00058 \times \sqrt[3]{1.5} = 0.001 \text{ in.}$$

The limits for the bore, therefore, will be 1.500 and 1.501 in. The deviations for the shaft are — 1.5 and — 3 tolerance units. Hence the limits for the shaft are 1.49[illegible] and 1.498 in.

Now let us take a 2-in. shaft and bore under the shaft basis to have a running fit of coarse quality. The shaft deviations are + zero and — 9 tolerance units, and the bore deviations + 9 and + 18 tolerance units. Nine tolerance units in this case amount to

$$9 \times 0.00058 \times \sqrt[3]{2} = 0.0065 \text{ in.}$$

and 18 tolerance units = 0.013 in. Hence the limits for the shaft would be 1.9935 and 2 in. and the limits for the bore 2.0065 and 2.013 in.

Tolerances in S. A. E. Standards

In the S. A. E. standards there are a good many examples of tolerances and these reflect modern American practice which, however, is not based on a unified or standardized system. For instance, on poppet valve stems a tolerance of 0.001 in. is allowed and both limits show downward deviations from the nominal size, the stem being intended to be a free sliding fit in the reamed bushing. Shanks of connecting rod bolts are dimensioned so that the maximum diameter is identical with the nominal size and the minimum from 0.002 to 0.004 in. smaller, according to the nominal size. The starting crankshaft end has limits of 0.998 and 1.000 in. and for the attached starting crank the hub bore limits are 0.9990 and 1.0005 in., while for the removable starting crank the hub bore limits are 1.010 and 1.015 in. This evidently corresponds to the shaft basis and tolerances to one side of the zero line. The tolerance on the shaft is a little larger than that corresponding to the plain fit of the German system. On rod end pins both deviations from the nominal size are negative, on the ½-in. size — 0.004 and — 0.007 in., for instance. The holes in the rod ends through which these pins go have both positive and negative deviations, + 0.001 and — 0.002 in. for the ½-in. size, for instance. The practice represented by these figures does not seem to fit in with any of the systems above discussed. In splined fittings the bore basis and tolerances to one side of the nominal dimension are used.

Tolerances in Ballbearing Mountings

The proposed standard ballbearing mountings submitted to the S. A. E. last winter correspond neither to the shaft basis nor to the bore basis. The inner race should be a press fit on the shaft. Let us take the 25 mm. bore size. For a high precision fit, according to the German system the tolerance on the shaft diameter would be 0.00057 in., the proposed tolerance was 0.0005 in. The tolerance on the bore, according to the German system would be the same, that is, 0.00057 in., that in bearings, according to the American standard is 0.0006 in. The maximum allowance in the German high precision press fit is + 2 tolerance units = + 0.00114 in., the minimum, zero. In the proposed American standard the maximum allowance is + 0.0009 in., the minimum, — 0.0002 in. Hence the tolerances on this size of bearing and shaft corresponded very closely to the German high precision fit, and the allowance lies between the German press and light press fits, somewhat closer to the former.

If now we take the largest size of bearing listed, with a bore of 205 mm., we find the following (the figures in parentheses following the different values correspond to the German high precision fit, hole basis, for the same nominal size). Tolerance on shaft, 0.0005 in. (0.00116); tolerance on bore, 0.0008 in. (0.00116); maximum allowance, + 0.0011 (0.0022); minimum allowance — 0.0002 in. (0). This shows that on the larger shafts the tolerance allowed in the proposed American system was less than half as great as that of the German high precision fit, which supports the contention made in the discussion at the Standards Committee meeting that the proposed tolerances were too fine.

The proposed housing bores are not held quite so close. For instance, for an 80 mm. outside diameter bearing the housing tolerance is 0.0010 in. (0.00085 in.); the bearing diameter tolerance, 0.0005 in. (0.00085 in.); the maximum allowance, — 0.0015 (— 0.0017 in. for sliding fit); the minimum allowance, 0 (0). For the largest size of bearing listed (400 mm. outside diameter) the figures are as follows: Housing bore tolerance. 0.0020 in. (0.00145 in.); bearing outer race tolerance, 0.0012 (0.00145 in.); maximum allowance, 0.0032 (0.0029); minimum allowance, (0).

Another S. A. E. standard involving a cylindrical fit is that of spring eye bushing and bolt tolerances. The tolerances on the eye bushings are set at + 0.001 and — 0.003 and those on the bolts at — 0.005 and — 0.008 in.

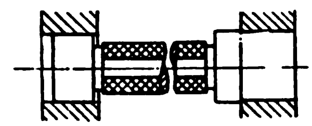
GERMAN INDUSTRIAL STANDARDS	**Precision Fit** Shaft Basis—Free Running Fit	G. I. STANDARD **41**

Abbreviated Designation for Free Running Fit—LL

Free running fits are used for joined parts which are to move relative to each other with plenty of play

"Go" Side

The gage must enter without force.



"No Go" Side

The gage must not enter but at most bite.

Dimensions in MM

Diameter Ranges	New Gage				Worn Gage		Gage
	Deviations		Maximum Play Calculated	Minimum Play Calculated	Go Side		
	Upward	Downward			Permissible wear	Deviation	
	No Go Side	Go Side					
1 to 3	+0.035	+0.018	0.040	0.018	0.003	+0.015	Plug Gage
Above 3 to 6	+0.045	+0.025	0.053	0.025	0.005	+0.020	
Above 6 to 10	+0.055	+0.030	0.065	0.030	0.005	+0.025	
Above 10 to 18	+0.065	+0.035	0.077	0.035	0.005	+0.030	
Above 18 to 30	+0.080	+0.040	0.095	0.045	0.008	+0.037	
Above 30 to 50	+0.095	+0.050	0.113	0.050	0.008	+0.042	
Above 50 to 80	+0.110	+0.060	0.130	0.060	0.010	+0.050	Flat Gage*
Above 80 to 120	+0.130	+0.070	0.152	0.070	0.012	+0.058	
Above 120 to 180	+0.150	+0.080	0.175	0.080	0.012	+0.068	
Above 180 to 260	+0.170	+0.090	0.200	0.090	0.015	+0.075	
Above 260 to 360	+0.190	+0.100	0.225	0.100	0.018	+0.092	Length Gage*
Above 360 to 500	+0.220	+0.120	0.250	0.120	0.020	+0.100	
Tolerance Units	—5.5	—3	6.5	3	0.5	—2.5	

*When flat gages or length gages are used the fits are apt to be slightly closer than when plug gages are used.

Sample German standard sheet giving tolerances for precision free running fits on the shaft basis.

Status of Movement in U. S.

So far not much has been done in the United States to standardize cylindrical fits, but the machinery for taking up the work exists here. The American Engineering Standards Committee has designated the American Society of Mechanical Engineers sponsor for standards on gages and gaging and the subject of fits would seem to come within the province of the committee appointed under this arrangement. This committee has recently issued a questionnaire dealing with the subject of fits and tolerances in general and no further steps will be taken until the replies to this questionnaire have been received and the information contained in them has been sifted and compared.

A line of standardization work closely related to that on cylindrical fits is screw thread standardization, and considerable progress in this has been made by the National Screw Thread Commission, a progress report of which was issued only recently. The National Screw Thread Commission recommends the adoption of four classes of fit for screw threads—loose, medium, close and wrench fit, and two qualities of work (or subdivisions) under medium and wrench fits. The commission also recommends the adoption of the bore basis. That is, the pitch diameters of the minimum nuts for all fits are the theoretical pitch diameters for the particular bolt size and all tolerances on nut pitch and other diameters are upward. The maximum screw is below basic for the loose fit, basic for the two medium fits and above basic for the close fit and the two wrench fits. The tolerances on all screws are minus.

If the recommended screw thread standards are adopted, as there is every likelihood that they will be (with possibly minor changes) the work of the Screw Thread Commission will furnish guidance for the Committee on Gages and Gaging or that on Allowances and Tolerances if one should be appointed. The Bureau of Standards has expressed itself as follows on the various questions arising in connection with the standardization of cylindrical fits:

"The Bureau is in favor of the use of the principle of the standard hole as against that of the standard shaft. There are, however, certain special cases in which the standard shaft is good engineering practice. For example, in machine tool building in cases where a single

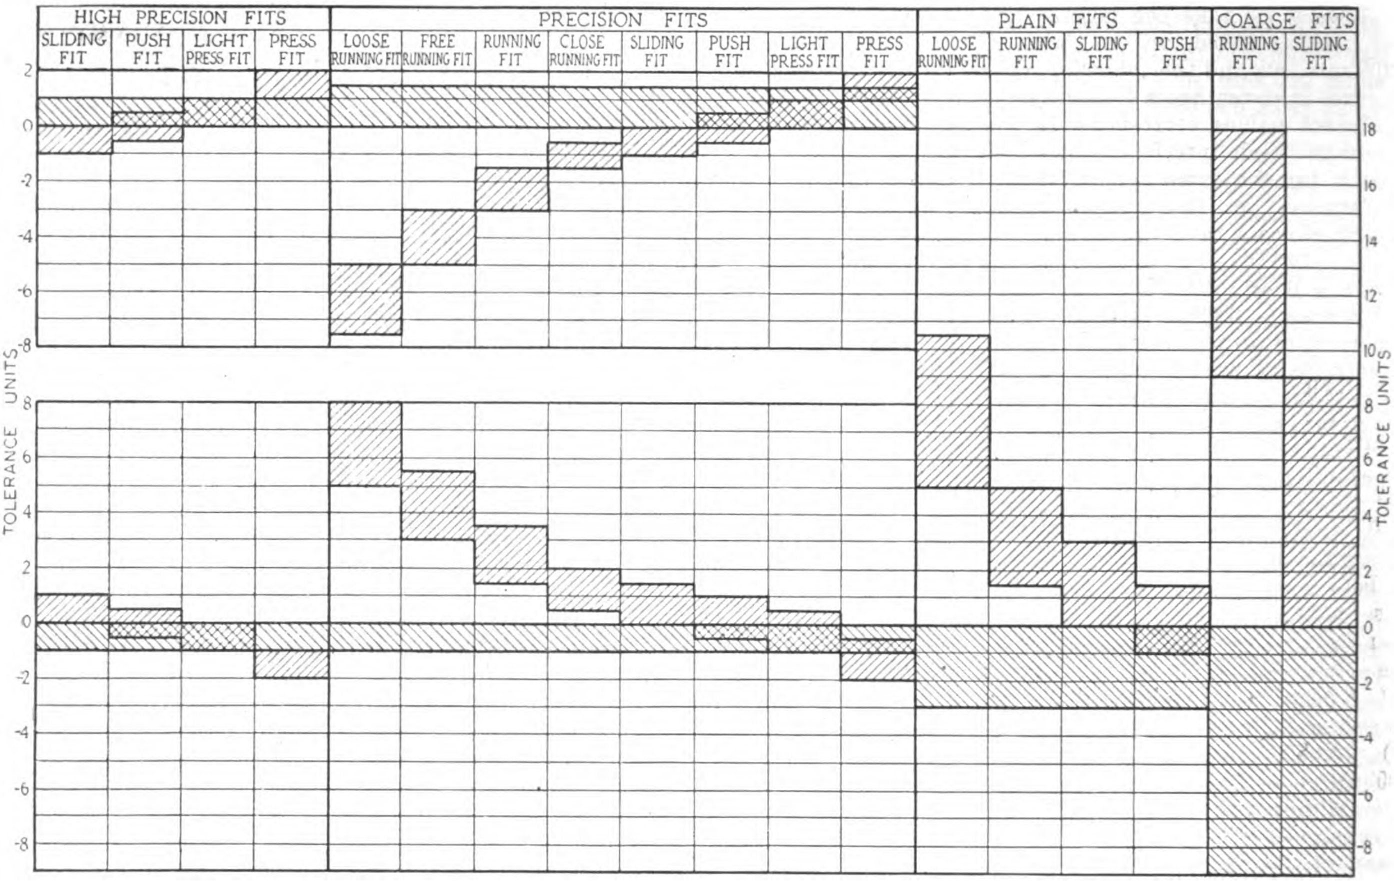


Diagram in upper left hand corner shows tolerances for hole basis. The larger diagram shows tolerances for shaft basis. Both diagrams represent the German standard system for cylindrical fits.

shaft runs in several bearings, requiring different qualities of fit, it is good practice to keep the shaft of uniform diameter and vary the journals to obtain the kind of fit required at each bearing.

"It is the opinion of the Bureau that in general the minimum hole should be of basic size and that the tolerances on the hole should be plus, and that the maximum

Definition of Terms

Fit in general denotes the physical correlation of two parts joined together, and is characterized by the clearance or interference.

Clearance is the free space between bore and shaft.

Interference is the amount by which the diameter of the shaft to be inserted exceeds the bore.

Allowance is the difference between shaft diameter and bore; it is positive when the shaft diameter is greater than the bore and negative when the shaft diameter is smaller than the bore. Positive allowance is interference; negative allowance, clearance.

Maximum and minimum limits are the extreme dimensions between which the actual dimensions of the completed part must lie.

Tolerance is the difference between the greatest permissible (maximum) dimension and the smallest permissible (minimum) dimension of a piece of work.

Minimum clearance is the difference between the minimum bore and the maximum shaft diameter.

Maximum clearance is the difference between maximum bore and minimum shaft diameter.

Minimum interference is the difference between the minimum shaft diameter and the maximum bore.

Maximum interference is the difference between the maximum shaft diameter and minimum bore.

Nominal dimension is the measurement which indicates the size of the part.

Deviation is the difference between the actual and nominal dimension.

The upward deviation added to or subtracted from the nominal dimension gives the maximum dimension.

The downward deviation added to or subtracted from the nominal dimension gives the minimum dimension.

Qualities of fit are grades of workmanship according to which the precision of fits is graded.

Unilateral system is a system in which there are tolerances on one side of the nominal dimension only.

Bilateral system is a system in which there are tolerances on both sides of the nominal dimension.

The bore basis is characterized by the following:

The bore remains the same for any particular quality of fit, that is, the diameter of bore does not change with a change in the class of fit, whereas the diameter of the shaft is made different according to the class of fit. The downward deviation of the bore is zero, therefore the zero line is the lower limit of the bore diameter. Shafts on which there are fits of different classes must be offset.

The shaft basis is characterized by the following:

The shaft diameter remains the same for any particular quality of fit, that is, the shaft diameter does not change with a change in the class of fit, whereas the bore diameter is made different according to the class of fit. The upward deviation of the shaft is zero, hence the zero line is the maximum or upper limit of the shaft diameter. Shafts on which there are fits of different classes may be either smooth or offset.

Storage Battery Equipment Important Design Problem

The designer has before him the problem of selecting storage battery equipment and of determining its position on the car. This article discusses the factors influencing performance and points out its intimate relation with owner satisfaction. Advantages of standardized equipment.

By Donald D. Blanchard

THE storage battery is to-day a most important part of automobile equipment. By the almost universal adoption of battery ignition in passenger-car practice, the satisfactory performance of the car has been inseparably linked with the performance of the battery. It is, therefore, a matter of prime importance that the automobile engineer choose wisely when selecting a battery for the car he has designed.
